### TYPHOID FEVER IN INFANTS.

BY I. N. LOVE, M.D.

ST. LOUIS, MO.

Time out of mind the general sentiment in the profession has been in favor of the thought that typhoid fever is not a disease incident to early childhood; but when we remember that the Eberth bacillus is the definite cause of the disease and that it is usually carried through polluted drinking water, the query may well be presented, Why should children who drink water escape typhoid fever any more than those of larger growth?

Age materially affects the liability to the disease, it being especially a disease of youthful vigorous individuals of 15 to 30 years. It is true that above that age it is much less frequent, although cases have been observed as late as 60 or even 70 years of age. Formerly it was often said that young children were never attacked, but Strumpell truthfully remarks: "This was because the disease was not recognized, for in reality it is only children under 1 year who seem to be seldom infected." When we recall that children under 1 year rarely drink water, their food being so largely fluid and being almost uniformly sterilized, we can readily understand why they should escape, and yet we may well question whether there is any special immunity against the danger of the Eberth bacillus in children under 1 year, the same as against most other infectious germs. Osler says upon this point: "It is not very infrequent in childhood but infants are rarely attacked." Murchison has seen a case at the sixth month. Cases have been observed which were congenital in which the mother had the disease late in pregnancy.

It has been my good or ill fortune to see during the past ten years in consultation, a number of children under the age of 2 years which presented mild intestinal disturbance, no marked tenderness over the bowels, a very high temperature, and where the apparent cerebral complications, delirium and stupor being prominent symptoms, were the apparent cause of death. In these cases in the death certificate the cause of death was usually given as congestive fever or meningitis. Two of these cases occurring within the past year, in both of which *post-mortem* examination revealed a pronounced error of diagnosis, has emphasized in my mind the thought that typhoid fever exists more frequently in early child life and in a serious form, than is generally suspected. It has generally been supposed that typhoid fever is milder when found among children than among the adolescent. Certainly, it has been noticed that intestinal complications and the characteristic ulcers are much less frequent, and as Strumpell says, this explains why "intestinal hemorrhage and peritonitis

are much rarer in children," but he truly observes, "severe cerebral symptoms are on the other hand very frequent."

As we know, the laity have long been disposed to apply the term "nervous fever" to this disease, and the term is truly justifiable, because we know how frequent and severe the nervous derangements are which occur in typhoid fever. Indeed, in the adult one often finds apparently mild cases where the temperature ranges low and yet where the nervous phenomena are very pronounced. Considering the undeveloped, sensitive nervous organization of the child, we have good reason to look for even more pronounced and serious nervous manifestations than in those older.

I present the following case:

A little girl of 18 months, child of a very prominent physician, was taken sick early in May with marked intestinal disturbance. The evacuations from the bowels were frequent and copious, accompanied by mucus and blood. The temperature ranged from 102 to 104 and on one occasion reached 105 degrees. There seemed to be a history of acute indigestion. The usual treatment was applied in this direction and the temperature was controlled by cooling baths. Flushing of the colon with medicated warm water was applied, followed by starch-water injections containing a few drops of laudanum for the purpose of calming the bowel and reducing the frequency of the operations which interfered with rest. During the early part of the attack, the child though having frequent operations, was noticed to be calm and gave no evidence of pain. Not until the fourth or fifth day, however, was marked mental obtundity observed, and the staring appearance of the eyes, together with the indifference to surroundings, impressed me with the fact that there was a cerebral complication. The course of treatment was continued and the supposed cerebral complication became more pronounced. Inability to distinguish light or sound and later a crossing of the eyes, apparently justifying a diagnosis of meningitis. The child died about the tenth day. *Post-mortem* examination developed the absence of meningeal inflammation and the presence of ulcerations of the glands of Peyer, showing us, the physicians in attendance, how little we knew of the cause of death.

The indications for treatment were the same. A recognition of the disease in advance would have probably made no difference, for the holding of the temperature down within safe range, the giving of a bland diet, the securing of rest, the administration of antiseptic remedies to relieve intestinal irritation would have been the indications no matter what the diagnosis. The one case was almost a duplicate of the other, and both have emphasized in my mind, together with other experiences, the thought that we must admit the possibilities of typhoid fever during infantile life even more frequently than we have been in the habit of doing, and that we must be on the alert in this direction in order that we may make a correct diagnosis.

When we recall the fact that the serious disturbance of the nervous centers, producing coma and eventually paralysis in infectious diseases, (whether due to the Klebs bacillus, the bacillus of Eberth, the pneumococcus or Fehleisen's bacillus of erysipelas)

are due to the toxin secreted by the bacilli (and the nervous phenomena in all these diseases are often very pronounced) we can readily appreciate that the child who is so prone to the hybrid and indefinite expression of disease, should often be listed for meningitis instead of typhoid fever.

Infectious cerebro-spinal meningitis is often accompanied by a rash similar to that of typhoid fever, and we can readily see how easy it is to make an error in diagnosis in this direction.

This short paper may be condensed into the following conclusions:

1. Typhoid fever occurs more frequently in children than is generally supposed.

2. The fact that ulceration and hemorrhage is much less frequent would explain the absence of pronounced abdominal symptoms.

3. The erratic, undeveloped and hyper-sensitive nerve centers in early child life explain why the toxic secretions of the Eberth bacillus should make cerebral symptoms very pronounced.

4. Given a child of any age with or without intestinal disturbance, with a continued elevated temperature, with or without marked evidence of cerebral disturbance, the possibility of the presence of the Eberth bacillus of typhoid fever should be constantly kept in mind.

#### FURTHER REPORTS ON THE ABORTION OF TYPHOID FEVER.

Read before the Mississippi Valley Medical Association at Hot Springs, Ark., Nov. 21, 1894.

BY JOHN ELIOT WOODBRIDGE, M.D.  
YOUNGSTOWN, OHIO.

When I accepted an invitation to present a paper at your last meeting, selected for my subject the question, Can typhoid fever be aborted, and answered it in the affirmative, antagonizing the teachings of the most learned professors in every medical college in the civilized world, I knew that I should be severely criticized, no matter how conclusive the evidence might be that my views were correct, and I fully realized, to use the words of a distinguished *litterateur*, that I might expect to stand but sit and sleep on pin points for some years.

Nothing, save the feeling of responsibility for every life sacrificed to typhoid fever, and the positive knowledge of its correctness could have forced from me that affirmative answer; looking back over twelve years experience without a death from typhoid, malarial, or any continued fever, to a preceding series of sixteen years with a death rate of 17 per cent. from typhoid fever alone; and from a time when my brother practitioners were having no better results than I formerly had. On July 17, 1893, I gave in my local society the names and residences of twenty-one cases of typhoid fever out of the large number I had treated. June 25, 1893, I instituted a series of clinical charts and began numbering with 20, presenting at your last meeting twenty charts, to show the modification of the temperature curve by treatment.

I deem it my duty as a conscientious physician, desiring only the welfare of mankind and the advancement of my profession, to continue the reports of cases falling under my observation. The many grateful letters and kindly words of encouragement I have received from brother physicians, and in some cases from the patients themselves, more than offset

the intolerant words and unkindly criticism I have met with from others.

Case 78.—Typhoid fever; name, J. J., age 6 years; residence, Darrow Street; date of admission, July 26, 1894. Result, temperature touched normal on the ninth day.

Case 82.—Typhoid fever; name, Ezra Main; age 26; nativity, American; occupation, farmer; residence, Trumbull County; date of admission, August 31, 1894. Commenced treatment August 30, one day before removing to the hospital. This patient was diagnosed as typhoid fever and treated a few days by Dr. T. H. Stewart of Church Hill. The symptoms becoming grave he feared to continue without a trained nurse, an expense which the family could not afford; hence he was turned over to me on the twelfth day of his sickness and moved nine miles in an ambulance to the Youngstown City Hospital, August 31. Bowels very tympanitic; tenderness in right iliac region; rose spots abundant; tongue coated, margin red.

I have no feeling of unkindness for those persons, because I know that truth being eternal will prevail, and that my critics of to-day, should we all live, will

themselves practice the antiseptic abortive treatment in time, and thus vindicate the position which I have been obliged to assume as a logical sequence of the facts I have observed.

I hope, however, that by going annually before some great medical body, reporting the cases in which the fever was aborted during the intervening periods and exhibiting the clinical charts, and premising that I see the cases at a reasonably early stage of the disease with no death to mar the record, that I may ultimately prove beyond the possibility of a doubt that I am not teaching the world to expect or demand more of my profession than it ought. Few can realize the anxiety with which one stands before a representative body like this to say that the greatest thinkers, that all of the great teachers in this most learned of the professions, the highest aim of which is to mitigate human suffering and to save human life, have promulgated an error which in the one disease under consideration costs more than 50,000

Case 85.—Typhoid fever; name, C. Smith; age 10 years; residence, Fosterville, Ohio; date of admission, Sept. 13, 1894. This boy lived in a neighborhood where there were several cases of typhoid fever. Was not confined to bed all of any day, but although presenting well marked symptoms of the disease rode several times on his pony to my office to see me. Temperature touched normal on the tenth day of treatment. September 13. Headache severe for several days past; epistaxis; bowels tender and tympanitic. September 17. Rode his pony to my office.

lives annually and unnumbered years of miserable sickness.

Since our last meeting, I have treated alone or in consultation, fifty-four cases of typhoid fever, without a death and with an average duration of treatment of about twelve days. I had, also, a case of pneumo-typhus and two or three cases sent by other physicians at late stages of the disease, one as late as the sixteenth day. I was called during the year to see one case on the thirty-fourth day of sickness when no treatment was needed and another at a somewhat earlier period but when the patient was dying of exhaustion and no treatment was possible. In the Section of General Medicine at the San Francisco meeting of the AMERICAN MEDICAL ASSOCIATION I reported my cases up to and including No. 75.

Case 76.—Pneumo-typhus; was in a desperate condition when I was called. She had been sick ten days; was coughing incessantly, raving wildly and having a profuse hemorrhage of the lungs; her pulse was 160; temperature 106.4. She was treated as a case of typhoid fever, with necessary additions in the later stages to meet the lung complication and made a good, though as you will see, not a rapid recovery. She lost all her hair.

Case 78.—John Joyce; was treated until the tenth day of sickness, by the family physician under a first diagnosis of malarial fever. Dr. Cunningham, who had seen some practice in Chicago accompanied me on my first visit having expressed a desire to see some of my work. I asked him to examine the patient and make a diagnosis. He did so, remarking that he should consider it a typical case of typhoid fever. Fearing that his words might frighten the boy's mother who was a stranger to me, I said: "Madame, you need not be alarmed; there is no danger from typhoid fever if it is properly treated." His temperature touched normal as you will see, on the eighth day of treatment.

Case 82.—Was sent to the hospital from the adjoining county of Trumbull, by Dr. T. H. Stewart. He was in the hospital ten days.

One of the best practitioners in Ohio made a diagnosis

Case 86.—Name, N. H.; age, 17 years; residence, Pine Street; date of admission, Sept. 20, 1894. This patient was under the care of another physician who had prescribed corrosive sublimate and one of the coal tar derivatives; enjoined perfect rest, milk diet; made a prognosis of several weeks severe sickness. I was called on the twelfth day of sickness. Found a typical case of typhoid fever and gave a prognosis of no danger and ten or twelve days sickness. She sat up, having a normal temperature on the tenth day, but a few days later she developed a phlebitis from which she has hardly recovered. September 20. Rose spots abundant, other symptoms characteristic.

of typhoid fever and called me in consultation to Case 83 which made a good recovery.

Case 86.—Was taken sick at the home of her parents, but her physician, recognizing the gravity of her condition had her removed to her sister's in a better and healthier locality, and had her put to bed down stairs, saying that she would be very sick for several weeks. He treated her until the twelfth day of sickness. I was subsequently called to attend this case and being unaware of the Doctor's prognosis, I told the family she would probably be much better in four or five days, and sitting up in ten days, which she did, but had an attack of phlebitis, which greatly prolonged the sickness.

The physician who called me in consultation to Case 83 was himself called in consultation to see Case 86, and after consulting, the two physicians went together to the family (in which there had already been three other cases and one death from intestinal hemorrhage) and told them that Mr. M.'s

symptoms were all so very bad that they advised that Dr. Woodbridge be sent for in consultation. Upon consulting with the doctors, I said: "There is no dan-

never is any danger of death from typhoid fever when taken at the stage at which we take this case." Yet his pulse was 100, and his temperature was 105.2;

Case 87.—Typhoid fever; name, O. M.; residence, ———; date of admission, September 22, 1894. This patient was the fourth case of typhoid fever in the family, one having died after an intestinal hemorrhage. His nervous symptoms being very severe, his attending physician asked for counsel. After consultation with his other physician, he asked to have me called, expressing to the family the opinion that the man would die under any known treatment of typhoid fever. Temperature touched normal on the tenth day of treatment.

Case 92.—Typhoid fever; Mrs. Yost; age, 24 years; residence, Hazelton, Ohio; date of admission, Oct. 27, 1894. Diagnosis by Drs. Bennett and Yost. Temperature touched normal on the tenth day of treatment. October 27. Bowels very tender and tympanitic; headache severe; nervous symptoms grave; sleepless; rose spots abundant. October 31. Pulse dicrotic. November 1. Pulse dicrotic.

Case 89.—Pneumo-typhus; name, P. G.; age 4½ years; residence McGuffey Street; date of admission, Oct. 16, 1894. Temperature touched normal on the eighth day of treatment. On the beginning of treatment nose bleed; headache severe; bowels very tympanitic; slightly delirious. On the twelfth day of treatment rose spots abundant. On the eighteenth day of treatment playing out of doors but very irritable and cross.

ger of a fatal termination. He will have a normal temperature in ten or twelve days;" but added, "there is not only no danger of death in this case, but there

Case 93.—Typhoid fever; name, Mrs. ———; residence, Thorn Hill, Ohio; date of admission, Oct. 27, 1894. Sanitary surroundings terrible! No fire in house (kitchen separate). No change of bed or body linen. No attention to the ordinary demands of cleanliness. Husband taken from her bedside to jail. Temperature touched normal thirteenth day of treatment. When first seen, intense headache; no sleep for three or four nights; very nervous; abdomen tender and very tympanitic. October 15. Three hemorrhages of bowels.

his other symptoms were extremely grave, I was not expected to see him again. Prognosis verified by the result.

*Case 91.*—Mrs. G., was seen in consultation with her attending physician. Her urine showed large quantities of albumen, and an abundance of both granular and hyaline casts. Her temperature never went above 101. She had considerable intestinal hemorrhage but made a good recovery.

*Case 93.*—When called in Case 93, I was told that she had been sick about ten days, but later information led me to believe that she had been sick twelve or thirteen days. Her condition, circumstances and surroundings were horrible; neither any part of her bedding nor her underwear were changed, nor were her face or hands or any part of her body washed during her sickness. There was a cooking stove in a back kitchen somewhere, and no fire anywhere else; it was cold weather with snow much of the time. The room adjoining hers, separated from it only by a loose board partition, was scrubbed once and when I went in the water was standing in puddles. On one of my visits I found the unemptied bed-pan on the bed, and on inquiring found her bowels had moved on the morning of the preceding day. Her husband was taken from her bedside to jail. She had three intestinal hemorrhages in one day. She made, as you see, a rapid recovery, her temperature becoming normal on the twelfth or thirteenth day. She lived so far in the country that I could not visit her every day.

*Case 94, 92 and 96.*—Dr. J. O. Yost, his wife and sister are in-

*Case 96.*—Typhoid fever; name, Kittle Yost; Hazelton, Ohio; date of admission, Nov. 5, 1894. Allowed solid food after the fifth day of treatment. Diagnosis made by Drs. Bennett and Yost. Nov. 5. Headache severe; cough incessant; abdomen tympanitic and tender, pressure produces gurgling.

interesting indeed. Mrs. Yost was under the care of Dr. B., a gentleman of unquestioned ability, who about a year ago passed through a very severe ordeal with typhoid fever, confined to bed six weeks, unable to attend to business an additional three months and even yet not over the effects of the attack. Seeing his patient growing worse, Dr. B. called on me about the tenth day and asked me to see her. I found as he said, a typical case of typhoid fever; the temperature  $104\frac{1}{2}$ ; the pulse varying between 110 and 134, which later became dicrotic. The bowels were very tender and tympanitic; marked dullness over the spleen; the margins of the tongue red, the center coated; much gurgling on pressure; a few rose spots which afterward became abundant; nervous and sleepless; very severe headache. A man boarding in a near by house dying, necropsy revealed extensive typhoid lesions and a perforation. The doctors asked if I considered Mrs. Yost in very great danger. I answered, giving my usual prognosis: "Typhoid fever is never dangerous if properly treated early." Two days later Dr. B. called my attention to Dr. Y., saying that he himself had typhoid fever. Examining him, I found his symptoms nearly as well marked as were those of Mrs.

Yost, save that his temperature and pulse were not so high or frequent and he had no rose spots.

He said if he were going to be confined to bed he should go home. I said: "Stay and attend to your practice. I assure you that you will be able to at least see patients in your office every day of your sickness," and he was.

Eight days later, Miss Yost was attacked with typhoid fever, not having said anything about being sick as long as she was able to sit up. Her temperature the day before I saw her was  $104\frac{1}{2}$ ; her pulse 100, and all her symptoms characteristic. I told the doctor that she would have to stay in bed three or four days perhaps, but would be well in ten days, and could eat solid food all the time.

This closes the record since our last meeting. Some of the cases diagnosed and numbered as typhoid may possibly have been some other fever, but whatever they were, they all recovered under the treatment of typhoid fever; and this treatment is the least harmful they could possibly have had, there being nothing in it that could possibly be injurious except the little bit of calomel, and of that the dose is exceedingly small, less than one one-hundredth of the dose usually given.

No sane man would dare to go into houses with three or four members of a family sick with typhoid fever, the temperature of some of the patients above 105 degrees and give my invariable prognosis, unless he knew that there was power in medicine to ward off the threatened danger. No man would dare to make the promises I have made for so many years, unless he knew he could fulfill them. Remember, I have invited the closest scrutiny of my cases, and should I have a death from typhoid fever, or fail to abort a case when seen early, it would be emblazoned all over this broad land. But had I twenty years instead of twenty minutes, and could take you back and show you all the evidences that proved to me that typhoid fever can be aborted; could I show you all the typical cases that have yielded to this intestinal antiseptic; show the awful complications that threatened the life; show the white-haired old lady, with the positive proof of a preëxisting Bright's disease, with her repeated intestinal hemorrhages; show you the old man of 73 years, whose young son had succumbed to an intestinal hemorrhage; show the young lady with a year-old ovarian trouble presenting a rounded fluctuating mass through the abdominal walls; show you the wife of Angus McPhee with the blood welling up from her lung, and show you, too, that all of these patients recovered, many of them under the most adverse circumstances, totally disregarding all of the things usually insisted upon as essential to recovery. Many of them with only such nursing as a young child could give. Some giving no attention to restrictions as to diet, and all allowed to use their own pleasure as to exercise and bathing, and yet with no death to mar the record. You would commend my course in making so great a sacrifice and even endangering my professional career in the interest of humanity.

In the abortive treatment of typhoid fever, an early diagnosis is of the first importance. Every case of typhoid fever should be put upon proper treatment the first time seen. There should be absolutely no exception to this rule. If you await the development of pathognomonic symptoms of typhoid fever before beginning treatment, you will not always succeed in aborting the disease. Therefore a diagnosis from any other disease to typhoid fever is wholly unjustifiable, but the reverse is always proper, because the best possible treatment for typhoid fever is also

a safe initial treatment for any disease for which it could be mistaken.

If you always begin proper treatment when you first see your patient, he will be well often before a positive diagnosis is possible, and you will be deprived of what might otherwise have been a valuable record, but your patient will be the gainer. And after all we are physicians first and investigators afterwards. Hence, when consulted by a patient who could possibly become a victim of typhoid fever, diphtheria, la grippe, pneumonia or any pathologic condition which would be benefited by an intestinal or systemic antiseptic or eliminant, begin at once the treatment for typhoid fever.

It must not be supposed that because I have begun treatment at almost every stage of typhoid fever and have treated so large a number of cases and have had no death from typhoid fever or any disease that could be mistaken for it for more than twelve years, that such results are always possible. These cases make the proof positive that typhoid fever can be aborted, but it does not follow that it can always be aborted, or even that every life can be saved when it has not been properly treated in its earliest stages.

Next in importance to an early diagnosis, if indeed it should not stand *first*, is, that your prescriptions be properly compounded of pure and active ingredients. Messrs. Parke & Davis have for years supplied most of the materials entering into my prescriptions, and latterly they have put up for me, tablets of formulas Nos. 1 and 2, and soft capsules of formula No. 3 in a most satisfactory manner.

Begin the treatment with a tablet of formula No. 1:

R. Podophyllin . . . . .	gr. 1-960.
Hydrarg. chlor. m . . . . .	gr. 1-16
Guaiacal carb. . . . .	gr. 1-16.
Menthol . . . . .	gr. 1-16
Eucalyptol . . . . .	q.s.

Sig.: Every fifteen minutes.

No laxative effect should be produced during the first twenty-four hours, the object being to secure the antiseptic before the eliminative effect of the remedy. During the second period of twenty-four hours, not less than five or six free evacuations of the bowels should be secured. Then formula No. 2:

R. Podophyllin . . . . .	gr. 1-960
Hydrarg. chlor. m . . . . .	gr. 1-16
Guaiacal carb. . . . .	gr. 1-4
Menthol . . . . .	gr. 1-16
Thymol . . . . .	gr. 1-16
Eucalyptol . . . . .	q.s.
R. Guaiacal carb. . . . .	gr. iii
Thymol . . . . .	gr. i
Menthol . . . . .	gr. ss
Eucalyptol . . . . .	m j

One or more tablets every hour or two should be given with No. 1 as frequently and in as large doses as possible without producing too much laxative effect, and as long as necessary if no symptoms of ptyalin (a wholly unnecessary complication), appear, in which event they must be discontinued promptly for a day or two, and if necessary chlorate of soda or potash given, returning as soon as possible to formulas Nos 1 and 2. The object is to give these remedies as freely as possible at first, and then so gradually reduce the size and frequency of the doses as to allow the movements of the bowels to become less and less frequent, until, as the temperature approaches normal, the

movements shall be reduced to one or two each day. About the fourth or fifth day of treatment begin No. 3 every three hours.

Every dose of medicine should be washed down with large draughts of distilled or sterilized water, or according to indications with some good laxative or diuretic mineral water.

This treatment begun early and intelligently carried out will, if the remedies are pure, active and properly prepared, abort typhoid fever and a death from the disease will be unknown.

## ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 948.)

### CHAPTER III.

#### CHANGES OF THE TEMPERATURE, PULSE AND RESPIRATION IN YELLOW FEVER.

Owing perhaps chiefly to the sudden origin, rapid progress, and singularly fatal nature of yellow fever, as well as the infrequency of the use of the thermometer in the investigation of the disease, but few facts of value relating to the definite degrees of temperature in the different stages of the disease can be found in the writings of various observers. Almost all observers, however, as Benjamin Rush,<sup>15</sup> J. Deveze,<sup>16</sup> Wm. Currie,<sup>17</sup> C. Caldwell,<sup>18</sup> Samuel Jackson,<sup>19</sup> P. Chas. A. Louis,<sup>20</sup> W. Arnold,<sup>21</sup> R. Jackson,<sup>22</sup> Lionel Chalmers,<sup>23</sup> John Lining,<sup>24</sup> A. M. F. Savarésy,<sup>25</sup> William T. Wragg, Daniel Blair,<sup>26</sup> John Davy,<sup>27</sup> Schmittlein,<sup>28</sup> and many others, concur in the statement that in the early stage of reaction or febrile excitement the temperature is elevated to a greater or less degree, in different cases, above the standard of health; and still further, that this elevation of temperature is not permanent, but at the end of from two to five days, in most cases, is succeeded by a decided fall; and although the symptoms may be of the gravest character and the patient *in extremis*, neither the elevation of the temperature nor the frequency of the pulse give any true indication of the danger.

Dr. John Lining, of Charlestown, S. C., appears to have been the first physician who recorded definite observations on the variations of the temperature in yellow fever. In his description of the American yellow fever, contained in a letter addressed to Dr. Robert Whyte, Professor of Medicine in the University of

<sup>28</sup> On the Temperature in Diseases, by Dr. C. A. Wunderlich. (Sydenham Society, page 405.)

Edinburgh, dated Charlestown, Dec. 14, 1753, and published March 7, 1754, the following general observations relate to the changes of the pulse, respiration and temperature in this disease: "After a chilliness and horror with which the disease generally begins, a fever succeeded, in which the pulse was very frequent till near the termination of the fever, and was generally full, hard, and consequently strong; in some, it was small and hard, in others, soft and small; but in all these cases, it frequently varied in its fullness and hardness. Toward the termination of the fever, the pulse became smaller, harder and less frequent. In some, there was a remarkable throbbing in the hypochondria; in the latter of which it was sometimes so great that it caused a constant tremulous motion of the abdomen.

"The heat generally did not exceed 102 degrees Fah.; in some it was less; it varied frequently, and was commonly nearly equal in all parts, the heat about the precordia being seldom more intense than in the extremities, when they were kept covered. In the first day of the disease, some had frequent returns of a sense of chilliness, though there was not any abatement of their heat. In a few, there happened so great a remission of the heat for some hours, when at the same time the pulse was soft and less frequent, and the skin moist, that one from these circumstances might reasonably have hoped that the fever would only prove a remittent or intermittent. About the end of the second day, the heat began to abate.

"The respiration was by no means frequent or difficult, but was soon accelerated by motion, or the fatigue of drinking a cup of any liquid.

"A nausea, vomiting or frequent retching to vomit, especially after the exhibition of either medicines or food, came on generally the third day, as the fever began to lessen; or rather as the fullness of the pulse, heat and disposition to sweat began to abate. Some, indeed, but very few, on the first day had a vomiting either bilious or phlegmatic.

"The strength was greatly prostrated from the first attack. The pain in the head, loins, etc., of which they had complained before the attack, was greatly increased, and in some the pain in the forehead was very acute and darting; but these pains went off generally the second day. The face was flushed, and the eyes were hot, inflamed, and unable to bear much light.

"The fever accompanied with these symptoms terminated on the third day, or generally in less than seventy-two hours from the first attack, not by any assimilation, or concoction and excretion of the morbid matter; for if by the latter, there would have been some critical discharge by sweat, urine, stool or otherwise, none of which happened; and if, by the former, nothing then would have remained but great debility. No; this fever did not terminate in either of these salutary ways, excepting in some, who were happy enough to have the disease conquered in the beginning by proper evacuations, and by keeping up a plentiful sweat, till the total solution of the fever by proper mild diaphoretics and diluents. But those who have not that good fortune, however tranquil things might appear at this period, (as great debility and a little yellowness in the whites of the eyes seemed to be the chief complaints, excepting when the vomiting continued), yet the face of affairs was soon changed; for this period was soon succeeded by the

second *stadium*,—a state, though without any fever, much more terrible than the first; the symptoms in which were the following:

"The pulse immediately after the recess of the fever, was very little more frequent than in health, but hard and small. However, though it continued small, it becomes soon afterward slower and very soft; and this softness of the pulse remained as long as the pulse could be felt. In many, in this stage of the disease, the pulse gradually subsided, until it became scarce perceptible; and this notwithstanding, all the means used to support and fill it; and when this was the case, the icteritions—like suffusion, the vomiting, delirium, restlessness, etc., increased to a great degree. In some, the pulse often being exceedingly small and scarce perceptible, recovered considerably its fullness; but that favorable appearance was generally of but short continuance.

"The heat did not exceed the natural animal heat; and when the pulse subsided, the skin became cold and the face, breast and extremities acquired somewhat of a livid color. . . . The respiration was natural or rather slow. . . . The vomiting or retching to vomit increased, and in some was so constant that neither medicines nor ailments of any kind were retained. Some vomited blood; others only what was last exhibited, mixed with phlegm; and others again have what is called the black vomit. The retching to vomit continued a longer or shorter time according to the state of the pulse; for as that became fuller, and the heat greater, the retching to vomit abated, and *é contra*.

"The debility was so great that if the patient was raised erect in the bed, or in some, if the head was only raised from the pillow, while a cup of drink was given, the pulse sank immediately and became sometimes so small that it could scarcely be felt; at this time they become cold, as in a horripilation, but without the anemic-like skin; their skin became clammy, the delirium increased, their lips and skin especially about the neck, face and extremities, together with their nails, acquired a livid color.

"There were many small spots, not raised above the skin, which appeared very thick on the breast and neck; but less so on the extremities, and were of a scarlet, purple or livid color. In women the menstrua flowed, and sometimes excessively, though not at their regular periods.

"There was such a putrid dissolution of the blood in this *stadium* of the disease, that, besides the vomiting of blood formerly mentioned, and the bloody urine soon to be taken notice of, there were hemorrhages from the nose, mouth, ears, eyes, and from the parts blistered with catharides. Nay, in the year 1739, or 1745, there were one or two instances of a hemorrhage from the skin, without any apparent puncture or loss of any part of the scarf-skin.

When this *stadium* of the disease terminated in health, it was by a recess or abatement of the vomitings, hemorrhages, delirium, inquietude, jactations, and icteritious-like suffusion of the skin, and white of the eyes; while at the same time, the pulse became fuller and the patient gained strength, which after this disease was very slowly. But when it terminated in death, these symptoms not only continued, but sooner or later increased in violence, and were succeeded with the following, which may be termed the third *stadium* of the disease, which quickly ended in death.

"The pulse though soft became exceedingly small and unequal; the extremities grew cold, clammy, and livid; the face and lips in some were flushed; in others, they were of a livid color; the livid specks increased so fast that in some the whole breast and neck appeared livid; the heart palpitated strongly; the heat about the precordia increased most; the respiration became difficult, with frequent sighing; the patient now became anxious and extremely restless; the sweat flowed from the face, neck and breast; blood flowed from the mouth or nose or ears, and in some, from all these parts at once; the deglutition became difficult; the hiccoughs and subsultus of the tendons came on and were frequent; the patients trifled with their fingers, and picked the nap of the bedclothes; they grew comatose, or were constantly delirious. In this terrible state, some continued eight, ten or twelve hours before they died, even after they had been so long speechless, and without any perceptible pulsation of the arteries in the wrists; whereas, in all other acute diseases, after the pulse in the wrist ceases, death follows immediately. When the disease was very acute, violent convulsions seized the unhappy patient, and quickly brought this *stadium* to its fatal end. After death, the livid blotches increased fast, especially about the face, breast and neck, and the putrefaction began early, or rather increased very quickly.

"This was the progress of this terrible disease through its several *stadia*. But in hot weather, and when the symptoms in the first stage were very violent, it passed through these stages, as Dr. Warren has likewise observed, with such precipitation that there was but little opportunity of distinguishing its different *stadia*; the whole tragedy having been finished in less than forty-eight hours."

Dr. Lining also records observations on the changes of the tongue, skin and urine which have been omitted from the preceding quotation, in order to present in a connected manner his accurate accounts of the changes of the pulse, capillary circulation, blood, respiration and temperature.

In his prognostics, Dr. Lining held that a sediment in the urine in the first and second day of the disease is bad, and the more copious the sediment is, the greater is the danger; bloody urine and all hemorrhages, excepting slight ones from the nose are bad; and the more copious they are, the greater is the danger; a suppression of urine, especially in those who in the course of the disease have had large discharges that way, is a certain sign of the quick approach of death.

Dr. Lining held that the yellow fever of America was a pestilential, specific contagious fever, imported from the West Indies, "which continues two or three days and terminates without any critical discharge by sweat, urine, stool, etc., leaving the patient excessively weak, with a small pulse, easily depressible by very little motion, or by the erect posture; and which is soon succeeded with an icteritious color in the white of the eyes and the skin, vomiting, hemorrhages, etc., and these without being accompanied with any degree of a febrile pulse and heat."

Subsequent observations have tended to confirm the accuracy of Dr. John Lining's comprehensive description; and the voluminous writings of Dr. Benjamin Rush, of Philadelphia, Drs. Samuel Latham Mitchell, and Edward Miller, of New York, and others a century later added literally nothing to the

fullness of his description; but on the contrary these writers, and especially Benjamin Rush, caused much subsequent confusion by confounding the endemic malarial, paroxysmal fevers of the paludal regions of North America with the specific yellow fever of the West Indies.

Savarésy<sup>29</sup> who observed yellow fever in Martinique in 1803 and 1804, affirmed that the heat rises often as high as 38 or 40 degrees of Reaumur—equal to 117.00 or 102.2 Fahrenheit.

Dr. John Davy<sup>30</sup> published in 1814 the first of his remarkable papers containing the results of his experiments in animal heat; and in 1816 he began his observations upon the temperature of man in various climates, in various diseases and under various states of rest and exercise, fasting and repletion in various races;<sup>31</sup> and in 1828 he established the singular fact that the human body may manifest a high degree of heat after death.

The following are the cases as reported by Dr. John Davy:

*Case 1.*—Aged 23 years; was admitted into hospital on July 30, 1828, laboring under symptoms (as it was supposed) of acute rheumatism, having some pain first in one shoulder, then in the other, followed by pain in the hips, attended with much pyrexia, and a very rapid pulse. He died on August 6, a few minutes after 7 A.M. As the weather at the time was very hot (Military Hospital in Valetta, Island of Malta), and dead animal matter putrefied rapidly, it was necessary to inspect the body as soon as possible. Accordingly, it was examined three hours and a half after death; when the temperature of the air of the room was 86 degrees. The appearances most remarkable, discovered on dissection, were extensive collections of matter in the right shoulder, among the muscles on each side of the spine of the scapula, with sinuses extending to the axilla, and around the capsule of the shoulder joint; and a lesion of the same kind, and as extensive, in the left hip close to the head of the femur, spreading through the glutei muscles; and marks of incipient inflammation (as ecchymosis) on the right hip. The viscera were apparently sound. The right cavities of the heart and the great vessels were distended with liquid blood. The body was slender but not emaciated. Its surface was warm; the deeply seated parts felt very hot, imparting a disagreeable sensation, almost like that of burning, to the hand in contact with them. The thorax was first opened and afterwards the abdomen. After partial exposure of the surface of the contents of these cavities to the air for about ten minutes, a thermometer was procured. Placed under the left ventricle of the heart it rose to 113 degrees, and under the liver, in contact with the lobulus spigelii, to 112 degrees.

*Case 2.*—Aged 27 years, a stout, robust man, died suddenly in barracks, on August 6, at about 1:30 A.M. The body was examined at 5 P.M. There was a good deal of reddish fluid in the ventricles, and at the base of the brain. The lungs were distended with black liquid blood, some of which had passed into the bronchii. There was very little blood in the cavities of the heart. The temperature of the air of the room was 86 degrees. As soon as the cavities of the thorax and abdomen were opened, the bulb of a thermometer was in succession placed under the left ventricle of the heart, and under the lobulus spigelii of the liver; in the former situation it rose to 108 degrees; in the latter to 107 degrees. Almost a quarter of an hour afterwards, introduced into the substance of the right lung, gorged with extravasated blood, it was 105 degrees.

The question will naturally be asked, Was the extraordinary temperature, in one case of 113 degrees, and in the other of 108 degrees, generated during life or after death? Dr. Varez had little hesitation in coming to the conclusion that it was generated before death, and generated probably in the same

<sup>29</sup> De la Fievre Jaune en générale, et particulièrement de celle qui a régné à la Martinique en l'an XI et XII 1803, 1804, 8vo. Naples, 1809.

<sup>30</sup> Philosophical Transactions of the Royal Society of London 1814, p. 590. Researches, Physiological and Anatomical, by John Davy, M.D. and R.S. Assistant Inspector of Army Hospitals, 1839, vi, pp. 141 248.

<sup>31</sup> Third Ed. Philadelphia, 1826, Res., Phys. and Anat., vi., p. 161.

way as the ordinary degree of animal heat experienced in health, or the extraordinary degree witnessed in febrile diseases. *A priori*, the effort of the heat-generating process, whatever it may be, can hardly be limited. In many birds, it raises the temperature of the body to 109 degrees, when in perfect health, and in man to 101 degrees, at least in the tropics, without deranging health; and it is easy to conceive that by increased activity or energy, it may exalt the temperature to the common febrile height, or to a height greatly exceeding that. But, destitute of life, in the opinion of Dr. Varez, there does not appear to be in the body any source of heat, any power of generating it, that is known. Putrefaction had not taken place in these bodies; even if it had, and had made progress, and were it even at its greatest height of activity, it is doubtful if it would be equal to the production of the effect in question.

It is a matter of regret that the temperature of the preceding cases was not ascertained by Dr. Davy before as well as after death; it is only known that the skin of the first case the day before he died was pungently hot.

These observations by Dr. Davy were of great value, in that they should have put medical inquirers on their guard as to the extreme limits of the degree of animal temperature, and especially of the blood in deep-seated parts. If the temperature of the body be 113 degrees, three hours after death, and if generated during life, before death it must have been still higher. Similar investigations were instituted by Dr. Bennet Dowler fifteen years later, in 1843, 1844, 1858, on the *post-mortem* heat of yellow fever and other diseases, the results of which will be fully examined in a subsequent part of the present discussion.

Subsequently, Dr. John Davy<sup>32</sup> made observations on the pulse and temperature in yellow fever, during his service in the West Indies. Thus in his notes to the work of Dr. Daniel Blair, on the yellow fever which prevailed in British Guiana from 1837 to 1842, Dr. Davy states that, "unusual slowness of pulse was very often observed in the yellow fever of Barbadoes, and commonly accompanied with undue coolness of skin, especially in the extremities; it was a very remarkable feature of the disease after its first invasion—the time varying in different cases. . . .

From the few observations which were made with the thermometer, on the temperature of men laboring under yellow fever in Barbadoes during the last epidemic, it did not appear to be high—when highest not exceeding 104 degrees Fah. in the axilla. In two instances trial was made of the temperature after death (four hours); on one (Fitzpatrick), that of the brain was found to be 98 degrees, of the lungs 100 degrees, of the heart 101 degrees (left ventricle), 100 degrees (right ventricle); in the other (Reynolds), that of the brain was 98 degrees, that of the lungs 102 degrees, of the heart 104 degrees (left ventricle); 103 degrees (right); of the liver 103 degrees. For the latter observations Dr. Davy was indebted to his friend, Staff-Surgeon Dr. Spence, who in the capacity of principal medical officer of the garrison of St. Ann, had ample opportunities to study the disease, of which, until attacked by it, he zealously availed himself.

Dr. Arnold,<sup>33</sup> in his "Practical Treatise on the Bil-

ious Remittent Fever" (yellow fever), devotes an entire section of his work (occupying 66 pages out of 320), to the illustration by tables and cases of the temperature of the system in the febrile diseases of Jamaica, and states in his preface that he considers the temperature of the system in febrile diseases to be one of the most formidable symptoms; and expressed the belief that the system when laboring under bilious remittent fever (yellow fever), "must inevitably give way to the cause which produces even a few degrees of thermal exaltation beyond 105 degrees of Fahrenheit's scale, and that all our remedies will have little effect if we find it 110 degrees during the first or second stages."

The observations of Dr. Arnold were begun in 1819, and continued for twenty-five years, and he prefaces his observations on the changes of temperature in yellow fever, remittent fever, intermittent fever and typhoid fever, by the results of his investigations on the normal temperature of 107 subjects of all denominations, ages and sexes, including Creoles, black laborers, domestics, carpenters, mulattoes, white natives and Europeans; and the mean of that whole series was 98.19 degrees F., which Dr. Arnold considered a correct estimate of the temperature of the system in health in a climate like that of Jamaica. Dr. Arnold says: "*I believe there is no study more calculated to improve the healing art, or to throw more light on the nature of febrile diseases, than a minute attention to the state of the temperature of the system.*" . . .

I shall next point out the deviations which occur in consequence of febrile or preternatural heat, by a series of cases and observations, for the purposes contemplated in the inquiry, and I think it will be seen that the system is not capable of having any great augmentation of heat from morbid causes, without incurring serious, and sometimes irreparable mischief. In fever, particularly of the remittent form, the whole power of the animal economy is deranged—all its healthy functions are suspended; digestion is only imperfectly performed; the mental energy is much weakened by the agent which causes the fever, the ardent heat and rapid circulation; the heart is laboring and appealing for relief; the whole system is screwed up, as it were, to its highest pitch of excitement. *The heat, at this time, is at its utmost limit, and if continued for many hours, the extinction of life would in all probability result, in consequence of various changes or decompositions taking place in the blood. The exact degree of heat which is necessary to achieve this end has hitherto not been very accurately ascertained; it will require much diligent investigation to settle the point. The ingenious Dr. Hales believed "the heat of the blood in high fever to be 136 degrees."* This is irreconcilable to anything I have witnessed during twenty-five years' practice. Boerhaave also made various experiments, and he seems to think that "*terribly mischievous work might be effected by a degree of heat above 106 degrees, for, as he asserts, the serum of the blood would be coagulated.*" And he further asserts that *the natural heat of the blood of a human creature approaches very nearly the degree of coagulation.* Hippocrates, 4 de Morb., 23, observes: "Such a degree of heat, if neglected or wrongly managed, may indeed dissipate the more thin and watery parts, and so gradually thicken the

<sup>32</sup> Some Account of the last Yellow Fever Epidemic of British Guiana. By Daniel Blair, M.D., Surgeon-General of British Guiana. Edited by John Davy, M.D., F.R.S., etc. London, 1852, pp. 77, 78.

<sup>33</sup> A Practical Treatise on the Bilious Remittent Fever; its Causes and Effects. With illustrative Tables and Cases on the Temperature of the System in the Febrile Diseases of Jamaica, etc. By W. Arnold, M.D., etc. London, 1840.

whole mass of blood; have had enough effects that way, if it do not bring on a putredinous thinness." This was evidently but supposition; the serum of the blood or the white of an egg, requires a degree of heat to coagulate, which no living animal can bear, notwithstanding the puzzling tricks of fire-eaters and such mountebank impostors, who thrust themselves into ovens heated sufficient to bake a leg of mutton. Water at 108 degrees is too hot for the hands for any length of time; yet there are some persons, from custom, who can handle very hot pieces of iron; but such instances are only sufficient to form an exception to the rule and require no further comment."

Dr. Arnold records several fatal cases in which the temperature ranged from 108 to 110 degrees in the axilla. In three cases of yellow fever recorded by this physician, the temperature reached 110 degrees, and a similar degree of heat was observed in several cases during life by Dr. Bennet Dowler in 1843, 1844 and subsequently. In 1843 he began a remarkable series of investigations on the temperature of the heart and axilla during the various stages of yellow fever, and of the different organs after death. His original paper was first transmitted to, but not published in full in the *Western Journal of Medicine and Surgery* during the winter of 1843-44. Dr. Dowler continued his observations on the temperature in yellow fever and other diseases during a period of sixteen years,<sup>34</sup> and he established the fact that the temperature of the internal organs may attain after death a degree of heat equal to that witnessed by Dr. John Davy in the Island of Malta in 1828, viz., 113 degrees. Dr. Dowler confirmed the accuracy of the statement of Dr. Arnold, of Jamaica, that the temperature of the axilla in yellow fever may reach 110 degrees F.; and he also demonstrated that patients may recover from yellow fever whose temperature in the axilla has reached 109 degrees.

Dr. Dowler also demonstrated that, as a general rule, the temperature in the early stages of yellow fever is higher in fatal cases than in those which recover. Thus, in one series of cases of yellow fever, taken without selection, the following results were obtained: Fifteen patients who recovered, whose temperatures were taken at a period which averaged fifteen and one-third hours after the invasion, and afforded a mean temperature for the hand of 101.8 degrees, and for the arm-pit 104.84 degrees; nine persons who died, gave an average of, twenty-two and one-third hours after the invasion, for the hand, 103.62; for the arm-pit, 105.44 degrees.

The maximum of these classes coincided, but not the minimum. In those who died the average was higher; in the hand, the maximum reached by both was 107 degrees; the minimum in the hand among those who recovered was 95 degrees, and of those who died 99 degrees; the maximum of the former, in the axilla, 107 degrees; of the latter, 109 degrees; the minimum of the former, in the same region, 102 degrees, and of the latter 100 degrees, the latter being in *articulo mortis*.

Full justice will be done to the labors of Dr. Bennet Dowler in that portion of this chapter which relates to *post-mortem* heat in yellow fever.

Dr. Daniel Blair,<sup>35</sup> in his last published report on

the "First Eighteen Months of the Fourth Yellow Fever Epidemic of British Guiana," says: "High temperature of the body seems to have persisted longer through the stages of the disease in this epidemic than in the past. There is great irregularity in the temperature of the surface; sometimes the forehead is the hottest part of the body, and occasionally the chest. The uncovered portions of the body in the latter stages are easily reduced in temperature; and thus while the exposed chest and extremities may feel cool to the touch, the axilla may raise the thermometer to 102 or 103 degrees. The highest temperature I have observed during the course of the disease was 107 degrees Fah."

According to Dr. Wragg,<sup>36</sup> in some cases of yellow fever, the thermometer indicated a temperature of 108 degrees in the arm-pit, and 105 degrees on the chest.

Dr. Robert N. Lyons,<sup>37</sup> has recorded valuable observations on the relations of the pulse and temperature in the yellow fever which prevailed in Lisbon, Portugal, in 1857. Dr. Lyons arranges the cases under five groups, viz.: 1, the algid form; 2, the sthenic form; 3, the hemorrhagic form; 4, the purpuric form; 5, the typhus form.

(To be continued.)

## NOTES ON THE MAIN CHANNEL OF THE SANITARY DISTRICT OF CHICAGO.

Read before the Civic Federation of Chicago.

BY J. W. BEARDSLEY, C. E. (CORNELL UNIVERSITY.)

It is impossible within the few minutes at my disposal to more than cursorily touch upon the following general points relative to the main channel of the Sanitary District of Chicago:

1. A general description of the present progress of the work.

2. Some of the benefits accruing to the residents of Chicago upon the completion of the channel.

3. Points of interest in a tour of the line.

Of the well-known facts regarding the origin of the project, the labor involved in its legal birth and the imperative demands of sanitation for immediate relief, I will say nothing. The existing result is a channel under process of construction and about thirty miles long. The eastern terminus is at the intersection of Robey Street with the west branch of the south fork of the river, the grade of the bottom being about twenty-four and one-half feet below the Chicago datum plane, or the low water of Lake Michigan; thence it extends westerly, through the ancient water course of the Great Lakes to the Gulf, to the lower terminus at Lockport, where the bottom has an elevation of thirty feet below the Chicago datum plane.

The line is separated naturally into four divisions by the cross sections, and by the nature of the material to be excavated.

From the eastern terminus at Robey Street to the lower part of Section F, a distance of about nine miles, the material is of a nature to be readily excavated without interference to navigation or discharge whenever, in the future, sanitation demands a larger channel. Therefore, the area of the cross-section is a

minimum being held to a bottom width of 110 feet. This section is designed to carry 300,000 cubic feet of water per minute. The average cutting is thirty-seven feet deep.

Near the lower end of Section F, the material becomes more difficult to excavate and is designed for the maximum discharge of 600,000 cubic feet per minute, a quantity sufficiently large to so dilute the sewage of 3,000,000 inhabitants that the effluent will be harmless for manufacturing purposes. Here the cross-section is expanded to 202 feet on the bottom with side slopes of 2 feet horizontal to 1 foot vertical. The maximum velocity is about twenty-one inches per second. The average cut is nearly thirty-six feet for the next five and one-half miles.

The third natural division beginning near Willow Springs, marks the appearance of rock, the glacial drift forming about two-thirds of the material to be excavated. The cut averages about thirty-seven feet. Here the cross-section is decreased to 160 feet at the bottom and 163 feet at the top of the channel giving, practically, vertical sides. Retaining walls, extending from the rock up to five feet above the datum plane, form the sides of the channel. This bottom width of 160 feet controls the remainder of the line. Here, also, the union between the bottom widths of 160 feet and 202 feet is made. The retaining walls extend out as wing walls, to the required form of the preceding section.

The grade has an increment corresponding to the decrease in area of the cross-section and still provides for the maximum discharge of 600,000 cubic feet per minute. This requires the velocity to be increased to thirty inches per second, or two miles per hour.

Near the eastern end of Section 7, begins the fourth natural division; the glacial drift practically disappears, forming only about 3 per cent. of the total excavation for the remaining nine miles. The average cutting through *solid rock* is about thirty-three feet. This unparalleled rock excavation has necessitated the use of channeling machines for cutting vertical sides, drills to prepare the rock for blasting, and various conveyors for removing the shattered rock after it has been loaded by hand into skiffs or buckets. The end of this division and the western terminus of the main channel—Section 15—is partly built up and partly excavated and marks the location of locks, when the channel is finally open to navigation; but for the present it will be the site of the controlling works, by which the discharge of the new channel into the Desplaines River may be regulated. These works must provide for the surface fluctuations in Lake Michigan, which would result in an extreme oscillation of about thirteen feet at the controlling works. The surface of the water at the controlling works is some ten feet above the surface of the Desplaines River, which makes a rapid descent for about four miles to Lake Joliet. It will require extreme care to safely dispose of this immense volume of water over such a declivity, and it also suggests the enormous energy which could there be developed, estimated by Mr. Cooley to be 55,000 horse power between Lockport and Joliet, and 45,000 between Joliet and La Salle. Such a power and such a water-way have caused in similarly located places, phenomenal growth, and may form a source of income to the sanitary district of no mean moment.

The expenditure of \$3,000,000 (actually \$2,606,-

227.92) for a right of way has received its share of criticism. It would be a paradox to find a charitable object or institution, a financial success. But measure, if you can, the development of the city along such an avenue of commerce, the value of adjoining lands, which the trustees with keen foresight have added to the assets of the sanitary district, wharf privileges and warehouse rentals, and show that within the lifetime of some of us this same right of way may not prove a magnificent investment for meeting bonded indebtedness, or, for the expenses of maintenance and development.

The estimated rock excavation on Sections 7 to 14, inclusive, gives a total of 8,189,152 cubic yards of rock in place. This will expand into 14,333,333 cubic yards of broken stone on the sanitary right of way, at the very edge of an extensive water course. This is an amount sufficient to build 3,257 miles of street, having a road bed 30 feet wide and using an average depth of 9 inches of broken stone. It would build 12,217 miles of country road 12 feet wide and with an average depth of 6 inches, thirty-one and one-half times the length of the State of Illinois, from Chicago to her antipodes; or, furnish the foundations, and it would give a path 2 feet wide and 2 inches deep from Chicago to her lunar neighbor.

Financially, it is more economic policy for the taxpayers of the sanitary district to place untainted and above suspicion, their magnificent source of potable water by one large outlay, than to keep themselves perpetually subject to expense in extending water supply tunnels and in the hopeless pumping of the Chicago River sewage into the Illinois and Michigan Canal, which stands a menace to health throughout its entire course, and of which it has been aptly said: "It is frequently worse but never better."

Sanitation is a measure of civilization. Advancement requires time. Public opinion is called safe because it is conservative; but it is dangerously conservative in lines of advanced sanitation.

It is not possible to give a money value to sorrow, to losses entailed by useless sickness and death, and to the increase of crime and pauperism always accompanying filth and squalor, or, to place a value upon increased longevity and good health—the working capital of both unskilled labor and of the leaders in thought and action. But let us attempt to find a money value for a disease typical of polluted water and inferior sewage disposal. From typhoid fever in the years 1890, 1891 and 1892, the State Board of Health reports an average of 1.18 deaths per 1000, and this dread disease has been almost an epidemic here during the past decade.

Of typhoid fever, twenty-eight English cities give an average decrease, brought about by sanitary measures, of 39 per cent. Likewise, Boston, Brooklyn and New York obtained a decrease of 41.5 per cent., and I believe that the workings of the main channel of the sanitary district will bring to Chicago the beneficial decrease of 50 per cent., but to be more conservative, place the decrease at  $33\frac{1}{3}$  per cent. Assume a population of 1,500,000 and a reduction of the death rates of 1890 to 1892 by  $33\frac{1}{3}$  per cent. and we have a saving of life from typhoid fever alone of 585 persons per year. Assume only one-fifth of these to be bread-winners, supporting the average family of five. The city would save on this basis the support of 117 such families or 468 such persons, costing not less than \$150 a year for five years. This

moderate hypothesis results in an annual saving to the tax payers of \$355,000. To this add a saving of \$25 for each funeral involved, and the moderate fee of \$10 for medical attendance for each of these 585 useless deaths; this gives the sum of \$20,475. Assume ten cases of serious illness for each death, at an expense for medical attendance and enforced idleness of only \$15. This adds to the sum \$87,750. Thus the grand total saved per year by the reduction in typhoid fever alone is \$463,225. This sum capitalized at 4 per cent. per annum gives \$11,500,000, nearly one-half of the total expenditure of the sanitary district of Chicago.

The city of Chicago is located upon the bed of a comparatively recent swamp, and is specially subject to zymotic and enteric diseases, but her death rate *should be below* the normal on account of the continuous increment to her population of men, young, robust and ambitious.

The increased resistive powers of the system, the increase in capacity for thought and work, in morality and independence, resulting from the causes that decrease a death rate, can not be measured by sordid money values. But considered from the above standpoints, we can but feel and admire the wise and intense philanthropy which characterized so thoroughly the early promoters of the sanitary scheme. Aside from sanitation, the national importance for warlike maneuvers, and the international commercial importance of such a watercourse to Chicago can not be passed by. I quote from a brief by Mr. Cooley:

"Sitting at the pass of two continental valleys, a great waterway to the Atlantic, a great waterway to the Gulf, the center of a territory as resourceful as the world can show—her latent interest is awakening; she would restore the ancient outlet of the lakes; her thinking men are realizing that this old portage may become the Bosphorus of America, like the Constantinople of old, to possess which was to rule the world."

To the tourist the massive machinery, almost intelligent in its power, the proportions of the canal already excavated and the corresponding spoil banks attract, generally, the most attention, and are certainly worthy of more than a casual visit.

The huge dipper dredges on the two sections nearest the city, rapidly eat their own channel for floatation. West of these are the inclines, the bridges spanning the spoil banks, the belt conveyors and the cantilever conveyors operated in connection with steam shovels. All are movable parallel to the axis of the main channel, and are effective, ingenious and ponderous machines. Next are found the hydraulic dredges on Sections A and B, east of Willow Springs. Here the soft, low-lying ground is agitated beneath the water surface and, by means of powerful pumps, it is discharged from pipes at the desired distance from the channel. These sections will soon be unwatered, so that the hard underlying material may be excavated by steam shovels and other suitable machinery.

It is doubtful whether the men now engaged on the western portion will ever again see a rock cutting of such magnitude. Here are the cableways of 700 feet span, and the cantilevers which reach out 140 feet over the channel and 180 feet over the spoil bank.

The not uncommon occurrence of a rock blast shattering and hurling perhaps four thousand tons of rock, and consuming nearly a half ton of dynamite, is an impressive spectacle. To the geologist the present state of excavation affords an intensely interesting field. He has an unparalleled opportunity to study the varied constituents and complete sections of glacial drift as it was left in the remote times, cutting its striae and furrows in the underlying rock, and he will perhaps find the cutting boulder still in its abruptly ended furrow. In the alluvial deposits, large antlers, Indian relics, buffalo and mastodon bones have been discovered.

The vertical cuttings through solid rock present vivid object lessons in stratification faults and fissures, and the fossil hunter will be amply rewarded by finding nearly all the fossils characteristic of the Niagara limestone.

When the channel is complete from the standpoint of the sanitary district, Chicago can successfully combat scourges and epidemics. The Chicago River will become an outlet and will gradually purify itself and become a part of the network of lagoons joining the lake and the main channel through the north and south forks.

Chicago is rapidly becoming the first city of the Occident. In present achievements she has surpassed the wildest predictions of her founders. But useless will be her command of commercial centers, of railways and water courses unless she listens to the too apparent warnings of her streets and rivers, provides for her millions those most lavish gifts of Nature—pure air and pure water—and the higher gifts of civilization, pure social, moral and civic conditions.

It behooves every patriotic citizen to be relentless and persistent in the instruction of the masses for the accomplishment of such ends; then will the city of Chicago stand majestically, the Queen of the Western World!

### A SKIASCOPIC EYE.

BY JAMES THORINGTON, M.D.  
PHILADELPHIA, PA.

The rapidly growing popularity of the shadow test as an accurate method of obtaining the exact refraction of an eye under the influence of a mydriatic, prompts the writer to present an inexpensive eye for the use of the student or oculist who may desire to learn skiascopy at his leisure.

The eye as here shown, reduced one-third in size, is made of two cylinders of cardboard, one slightly smaller than its fellow, to permit slipping evenly into the other. Both cylinders are well blackened inside. The smaller cylinder is closed at one end, and on its inner surface is placed a colored lithograph of the normal eye ground. The larger cylinder is also closed at one end, except for a central round opening, ten millimeters in diameter, which is occupied by a +20 diopter lens; and on its outer surface is a colored lithograph of the normal eye with its appendages, the pupil being dilated, and corresponds to the central opening just referred to. In addition to this picture of the eye, there is also lithographed on the upper half of the periphery, the degree marks similar to those on a trial frame. To the lower half of the periphery are secured four pieces of cardboard, making two interspaces for trial lenses, and being square at the base, gives the eye an even resting surface.

On the side of the small cylinder is an index which records emmetropia, and the amount of myopia and hypermetropia according as it is pushed into or drawn out of the large cylinder. To use this eye, it is only necessary to bear in mind the two rules of skiascopy, governing the use of the plane mirror at the working distance of one meter, namely, that the light reflex seen in the center of the pupil moves,

1, with the movement of the light on the face in emmetropia, hypermetropia and in myopia, if the latter is less than one diopter; and 2, against (or opposite to) the movement of the light on the face in myopia of more than one diopter. If it is desired to study the band of light,<sup>1</sup> as seen in myopic or hypermetropic astigmatism, place the necessary cylinder from the trial set, in the back interspace, the degree marks assisting in finding the axis, and especially so if the axonometer is used.

This eye answers admirably for the beginner in ophthalmology, though not originally so intended, and as here illustrated and described, is made by Messrs. Queen & Co., of this city.

<sup>1</sup> Vide, *Annals of Ophthalmology* for January, 1895. "Thorington on Skiascopy."

## THE SYSTEMIC FACTOR IN THE TREATMENT OF DENTAL CARIES.

Read in the Section on Dental and Oral Surgery at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY G. S. DEAN, M.D.

SAN FRANCISCO, CAL.

It is not only because of its novelty that I have chosen my subject. I have chosen it, also, because it seems eminently a proper subject for presentation on an occasion like the present—an occasion whereon the practitioner of general medicine and the practitioner of dental medicine sit down together, to consider what they may do, jointly, for the welfare of mankind. The time was, in the not-distant past, when these two practitioners were sadly ignorant of one another's territory. But now the two have come together. They have familiarized themselves with one another's country. And now that they meet as allies in the cause of humanity, now that they are inquiring what they can do jointly for that cause to which their lives are devoted, it seems eminently proper to bring forward for discussion a subject which lies within the territory of both. It seems fitting on this occasion, to bring forward for attention the systemic side of the treatment of the commonest of dental diseases—the commonest in fact, of all the physical ills with which mankind is afflicted. That there is frequently (not always) a systemic factor in the etiology of dental caries, and that systemic treatment is often needed for the cure of this local affection, I shall endeavor to show. This being shown, it will appear that the disease has an interest, a practical interest, for the general as well as for the special practitioner. Hence it has seemed to me that, apart from other reasons, the subject which I have chosen has a peculiar appropriateness to the present occasion.

Let me introduce the subject by presenting a case. Let me do this, not merely because it is the proper way to introduce a new subject, not only because at the outset a single clear concrete presentation is worth a world of misty generalities; but let me do it also as a protest against the opposite course too often adopted and even defended by the presenters of new subjects, who, thoughtlessly, not having taken due note of the need of the human mind for concrete centers of knowledge, burden us with vague abstract or general statements without driving the initial nails on which these statements should be hung. Case reports are usually considered little more than cumberers of the ground; to be avoided or eliminated, or employed only as idle gossip to fill waste space or kill waste time. But this estimation can be due only to non-appreciation of the nature and the necessary conditions of human knowledge. A report of a case may, certainly, be uninformative; for it necessarily contains only what the reporter has seen, and he has perhaps not seen the items which are relevant. But for the presentation of new truth vividly, convincingly, for the purpose of rendering truth graspable or assimilable, there is nothing which can take the place of contact with the facts. With the assurance, then, that this method of presentation is right, and that the contrary method is wrong, I proceed to my narrative:

A gentleman sought dental examination, occasionally, during some years, his teeth being always found free from caries. At length, on the proximal faces of two of his teeth, cavities appeared.

Examination of the saliva revealed nothing worthy of note; no known form of salivary abnormality was present. We are not yet able to make satisfactory clinical salivary analyses. Inquiry developed the fact that, while the patient was "well," there was perhaps a trifling gastric and quite certainly a slight intestinal indigestion. Search for the cause of the disordered function, oral and intestinal, proved futile. Fillings were inserted; and there was given such hygienic attention, general and local, as seemed possible in the absence of etiologic insight.

About a year later, the filled teeth were found in good condition, but three other inter-dental spaces, in different parts of the mouth, were bordered by decay. At this time the general gastro-intestinal error, though not great, was sufficiently pronounced to be noticeable; and it was accompanied by rather frequent attacks of diarrhea, serous in character, sometimes supervening on exertion, at other times appearing without perceptible exciting cause. The patient, I thought, looked more pale and dull than before. He said that, though "well," he "felt somewhat run down."

Let me pause to set forth explicitly the salient general features of the case as they then appeared to me—there being no cognizable local abnormalities. Though there may have been periods of mucous inflammation, yet on the whole it may be said that whatever evil existed was beyond the reach of the dissecting knife; in other words, there was no apparent structural error; the troubles were purely functional. The failure of function was twofold, general and local; there was systemic atony or asthenia, and there was disorder of the intestinal tract; the digestive disorder being, I may add for explicitness, extended as distinguished from localized, and simple or apeptic as distinguished from complex or parapeptic. The relation between the local and the systemic derangement was beyond my view. I desired on this point (as I had done the year before) an expression of opinion from gentlemen more capable than myself of forming a judgment, but, failing to obtain it, remained in darkness. I probably accepted tacitly the hypothesis usual in such cases, namely, that the general asthenia was due to the digestive error.

The etiology of the predisposition to dental caries was, then, beyond my view. The dental disease seemed incapable of actual remedy, capable only of retardation by persistent or repeated local attention. The progress of the destruction of the teeth was again checked by filling the cavities, and the patient was brought to an active resolve to care locally for his own teeth (in the sense of keeping them clean) the moving cause being a realization by him of the fact that the predisponent of the dental caries was undiscoverable and therefore irremediable, and that therefore, to prevent destruction of the teeth, the effects of the predisposition must be met by local measures.

In a few weeks he re-appeared, complaining of oral and pharyngeal inflammation. Examination showed his disease to be amygdalitis purulenta—"quinsy." It terminated in suppuration, its character being thus conclusively established. Believing that suppurative amygdalitis is usually due to aërial poisoning, I determined to investigate more minutely than I had previously done the man's aërial surroundings, with some hope that I might thus reach the cause of his dental caries. But my investigation showed nothing. It was brief and eminently unsatisfactory. I ascertained that he had been living in and frequenting the same buildings during somewhat more than the period of his dental decay; but I found that his quinsy had supervened on an absence from home of a month's duration, and had appeared three or four days after his return. Apparently, then, since he had inhabited the same localities so long without quinsy, this disease had been contracted during his absence.

The synchronism of his habitation of his present abode and the caries of his teeth seemed suspicious, but inquiry, made on his presentation of dental caries and now repeated, showed that the house was apparently healthful; that it had in fact, every apparent advantage, and seemed above suspicion. The synchronism was therefore set down as a chance coincidence, and the problem of the dental caries was no nearer solution than before.

A few months elapsed, and the patient appeared again, suffering a second time with quinsy. The tonsillar abscess being evacuated, his case came up for consideration.

I hold, as I have said, that purulent amygdalitis is caused by aërial poisoning. I published some years ago, and justified by evidence fulfilling every logical requirement, the following theses: 1, suppurative amygdalitis is not in any way related to or dependent on mucous or catarrhal inflammation; it is a disease *sui generis*; 2, the predisponent of purulent amygdalitis is neither "plethora," "debility," nor "a previous attack;" it is the functional activity of the tonsil glands; 3, the excitant of purulent amygdalitis is never "cold;" it is always poison contained in the air inhaled (possibly, to include the suppurative amygdalitis which sometimes complicates scarlatina, I should add "or exhaled").

Holding this belief, and holding it not as an unproved hypothesis but as a theory established beyond reasonable doubt, I inquired concerning the patient's exposure to poison-bearing air. Where had he been? What had he been doing? Not the smallest light could be obtained from his answers. He had indeed, again visited the country. But he had avoided the house in which he had stopped during his previous absence from town; had not even been in the same region. And the visit to the country, in itself, could not be accepted as the cause of the amygdalitis; especially as he had frequently gone to the country in former years, and had never had the disease.

At length there was found a single similarity in the antecedents of his two attacks of tonsillar inflammation. Each had been preceded by an absence from his domicile for some weeks, and a return home. This one thing, the return home, was clearly shown by further inquiry to be that sole common antecedent which must be regarded as the cause. The quinsy poison was then in the house which the man had inhabited for years. Yet during these years he had had no quinsy. How was this? It was explainable by the fact that, while he was at home, his rooms were always well ventilated; whereas during his absence they were tightly closed, and he had on both occasions returned at night, and had slept on the infected pillows in the confined air of a month. (Have we not here, by the way, an explanation of the fact that purulent amygdalitis is more prevalent in winter, when houses are shut, than in summer, when they are open?)

The first etiologic insight being obtained, the view expanded rapidly. The patient was now, in spite of his quinsy, bright or vivacious. Though unable to talk before the evacuation of the pus, he said in writing that he "felt well," was "hungry," and that, while it hurt him to swallow, he got down "lots of milk and oysters." Sharply in contrast with this was his condition during his first attack. Then he had been "sick," dull, drooping; he had had no appetite, swallowing a little soup or gruel occasionally with reluctance; he had been, in a word, prostrated mentally and physically. Equally marked was the contrast in recovery. Now, when the pus escaped, he was "well;" that is, without any great amount of felt indisposition; before, for days after evacuation he had been "sick," and had remained "indisposed" for weeks; not, certainly, confined to bed, but markedly prostrated.

What was the cause of the difference in the accompaniments of the two attacks? In both there was approximately the same amygdalitis and pus formation. The inflammation produced, in both cases, systemic disturbance. But, since the inflammation was approximately the same in both cases, there was quite certainly something else which intensified the systemic symptoms of the first attack. Eliminating, then, the similarities of circumstance of the two attacks, I sought the difference of circumstance. The only marked difference found lay in the place where the disease was incubated and endured. The first or prostrating attack came on after the patient had been at home three or four days, and was endured at home. The second or non-prostrating attack came on and was endured away from home (the patient having

gone home after a month's absence, remained one day, and departed again). The prostration of the first attack was then quite certainly due, like the quinsy itself, to the house in which the patient lived.

The problem was solved. The etiology of the dental caries was at once transparent. The man had slept in a quinsy house; hence his quinsy. The atmosphere of the house (more strictly, of the rooms which he occupied) produced not only quinsy, but also general prostration; hence, in my judgment, the excessive "sickness" which accompanied the first attack. Did the cause which produced prostration when the man was ill also produce it, less conspicuously but no less really, when he was "well?" In other words, was the foul air of his domicile the cause of his atonic condition, and did this in turn produce his long continued digestive indisposition? I answered, with confidence, yes.

The step to the causation of his dental caries was easy. All dentists, probably, hold that the etiology of dental caries extends beyond the field of the microscope. All, necessarily, regard the saliva as a factor in the problem of dental decay. The evidence of an "epidemic constitution of the atmosphere" is as nothing in comparison with the evidence of an epidemic constitution of the saliva. How the saliva acts is an unsettled question. It is not even settled whether the saliva is, as to the teeth, a destructive or a protective fluid. Some dentists, not having seen any clinical evidence to the contrary, hold that acid saliva favors solution of the calcium salts of the teeth, and that alkaline saliva protects the teeth by neutralizing decay-producing acid. Others hold, with Dr. Black, the more elaborate hypothesis that normal saliva is protective, and that it acts germicidally; or, perhaps more properly, that this saliva modifies microbic life, diminishing the microbic secretion or so changing its character as to render it harmless. Others, with Dr. Palmer, regard the saliva as decay-producing, by reason of its being an electropoison fluid of greater or less power. Others, perhaps, without denying that there may be other features of salivary preservative or erosive action, believe that, the saliva being essentially protective to the teeth, one of its main prophylactic functions as regards dental caries is to dissolve and wash away such matter as tends to undergo acid fermentation—in a word, to cleanse the teeth. But whatever the hypothesis as to the mode of action, the fact, if not of salivary preservation of the teeth from caries, at least of the dependence of dental caries on the state or character of the saliva, must be universally admitted—if not explicitly declared, then implicitly held. It follows plainly that any state of the system in which the oral digestion or salivary function is impaired, is a state predisposing to dental caries. And, since the prostration of our patient impaired the gastrointestinal digestion, I considered it reasonably certain that it impaired also the oral digestion—that it gave rise to saliva deficient in caries-preventing power.

Feeling satisfied now that I understood the case, if not in all its details, at least sufficiently for practical purposes, I felt myself in a position to endeavor to effect the radical cure which was the patient's great desire. My remedial measure will be evident without statement. It was, as the patient was only a lodger, an immediate change of domicile.

The sequel showed that my advice was probably

correct. The man left the haunted house and remained under my eye for fully three years. His improvement in tone, in the feeling of "general health," was noted by himself, and the improvement in his appearance, though not very marked, was perceptible. The general digestive difficulty, I think, disappeared; it certainly diminished, for it ceased to be noticeable. But what was of special interest to me and is of special interest in the present connection, was the improvement in the oral digestion; the fact that though the patient became comparatively lax in the local hygienic care of his teeth, he ceased to suffer from dental caries. It is true that two (I think three) cavities of decay were found in his teeth shortly after his change of residence; but these cavities were residual to the period of decay, and they were not followed by others appearing year after year. In a word, after removal from the poisoned house, the man became, as he had been before his sojourn in it, "proof against dental microbes."

Such are the facts of the case as far as I saw them. I sought to extend or supplement them by a more minute inquiry into the aerial conditions which produced the atony—the incipient cachexia. But my supplemental facts proved meager. The unhealthy house was a comparatively modern structure, with large rooms, plenty of sunlight and good ventilation; it was, in fact, as I have already stated, prepossessing. The rooms occupied by the patient were a handsome suite in the second story. The only elegance lacking in them was that which, if it had been present, might have been blamed as the source of "sewer gas"—the stationary washstand. There was, indeed, no apparent connection with any sewer; nor was there, at first glance, any apparent source of quinsy-poison. The source of this poison was not, however, very difficult to find. Not only did green or rot-inviting lumber appear to have been used in the construction of the building, but the apartments of our patient were directly over a room and cellar in which usually provisions and sometimes articles not free from decomposition were kept, and the apartments communicated sufficiently with the lower rooms to allow air to pass. The patient's apartments were always "close," and "smelled badly" after being shut up for a time. The quinsy, then, was readily accounted for; a month's concentration gave a large stock of putrefactive germs. But the prostration, and its consequence, the oral indigestion? Was it due to the same poison, acting in small quantity for a long time? Or was it due to some gaseous accompaniment of the poison which produced the purulent amygdalitis—some chemic accompaniment of the physical poison? I hold the latter hypothesis because of familiarity with the effects of chemic poisons on tissues and consequently on organisms, plant and animal; but confess that I do not know. It may possibly have been due to something which had no connection with the amygdalitis, *e.g.*, to a leak of illuminating gas, whose depressing effect on the human organism may be seen by inspecting the workmen in almost any gas factory; but this supposition, infracting Occam's caution, "*Entia non sunt multiplicanda praeter necessitatem*," is rendered highly improbable by the fact that the systemic prostration accompanying purulent amygdalitis is usually very great, usually exceeds what one would expect the abscess (which constitutes the disease) to produce.

I have now laid a foundation for a statement of generalities. I have reported a case wherein, if my interpretation is correct, dental caries was caused by systemic error and was cured by systemic treatment. But before proceeding to state generalities, and to make, finally, the plea which I propose to make for a more intimate working together of the general and the dental practitioner, it will be well to clinch one nail which I have driven. It will be well, especially since the presentation of the nature and the clinical origin of purulent amygdalitis is so recent that it has probably not yet received general consideration, to justify by the facts of this case itself, as far as these facts go, my immediate certainty, on finding purulent amygdalitis, that the patient had been breathing foul air.

The facts are these: Before lodging in the house herein referred to, he had returned to San Francisco several times and had never had quinsy; while lodging in this house he returned twice (and only twice), and had the disease both times. Confirmation is furnished by the supplemental fact that, after abandoning this house, he returned to San Francisco three times at least (probably more), and did not have quinsy at any time. Clearly, then, the cause of the quinsy was not San Francisco; it was the house; in other words, it was not cold; it was poison in the air.

While I am speaking parenthetically, it may not be amiss to make another digressive remark; to call attention to the difference in the period of incubation of the two attacks of amygdalitis in the case reported. The first attack appeared probably three days and certainly not more than four days after exposure; the second attack did not present its initial symptoms till at least the fifth and perhaps the sixth day. The reason of this difference in time of incubation, though it seems fairly plain, as it has no relation to my present subject, I can not here discuss; I merely note the fact in passing, because it is seldom that we have an opportunity of observing two different periods of incubation of the same disease in the same individual at the same time of life.

Returning now to our subject we are ready for generalities. First, I may state that dental caries is not usually idiopathic. In this disease the general is not dependent on the local; it is the local which is dependent on the general. We speak of "frail teeth" as "prone to decay," or, more flatly, say that teeth decay because of their frailty. But when we speak thus we do not, or at least should not, mean literally what we say. If the salivary function (which is directly dependent on the general or systemic condition) is normal, the teeth, however frail, are safe from caries. And, contrariwise, the strongest teeth, though more resistant than frail teeth, will, under adverse systemic conditions, succumb to decay.

Next let me, as well as I can in a brief space, discriminate between idiopathic and systemic or symptomatic dental caries. Generally, I may say that cavities of decay on the morsal aspect of a denture are not to be considered as of systemic origin. To this rule, however, the exceptions are exceedingly numerous; they are based on this consideration: Rapid decay on any aspect of a denture, is to be regarded as due to systemic disturbance. Generally, again, it may be said (the exceptions are few) that decay on the proximal or buccal aspects of the teeth is symptomatic or of systemic origin, and calls for

something more than local treatment. It is true that we sometimes find cases in which we can feel reasonably certain that there is a direct salivary defect; cases of idiopathic salivary deficiency. But such cases are so rare as to throw the presumption on the other side. We may safely say, then, that proximal decay is to be generally regarded as a result of distant disorder or systemic depression.

Let me repeat here, to avoid possible misinterpretation and, incidentally, to be more explicit:

1. Dental caries is commonly due to fermentation of food, and occurs only where food lodges or remains for a sufficient length of time to undergo fermentation; it occurs, that is, only where there are lodging-places for food, *i. e.*, on the proximal faces of teeth which stand close together, on the buccal faces where the gum forms a pocket for the retention of food, and on any face where deep sulci, pits or fissures hold food till it undergoes fermentation. Those exposed or smooth surfaces of teeth where food can not lodge are always free from decay.

2. Normal saliva prevents dental caries, either by preventing decay-producing fermentation, or by overcoming the effects of this fermentation. It is in fact preventive of this fermentation or its results to a greater extent than one would, *a priori*, think possible. The saliva has scanty access to interdental spaces more or less filled with food; yet, in spite of uncleanly habits, normal saliva prevents proximal decay. The saliva can scarcely reach the filth-covered cervico-buccal portion of the teeth of the uncleanly; yet the dirtiest teeth are often free from buccal caries. Again, fissures and pits penetrating the enamel would be expected invariably to become seats of decay; but where the saliva is normal such fissures and pits are usually innocuous; they do not, in health, become centers of caries.

3. Anatomic (*i. e.*, macroscopic) faults of the teeth, such as pits and fissures, and errors of location, such as over-lapping, are sometimes so great as to lead to decay in spite of normal saliva. Decay due wholly to this cause is, however, rare except in teeth which, besides having the gross defects mentioned, are microscopically (histologically) defective; so-called "frail" or "soft" teeth—teeth wherein the mineral matter is lacking in solidity of structure, either as a whole or in spots, or, as may be the case, both as a whole and in spots; and even in teeth which are decidedly frail, pits and fissures of moderate size and depth, and irregularities of moderate extent, are, with normal saliva, innocuous.

4. "Frailty" or histologic defect of the dental tissues, even to the extent of what might not improperly be called idiocy of dental structure, rarely if ever produces idiopathic dental caries.

5. Decay-producing error of saliva is undoubtedly sometimes idiopathic. We find differences in the saliva of different persons, both in quantity and in quality, under circumstances which render us reasonably confident that they are not due to what we may for brevity, call systemic disturbing causes.

6. Idiopathic dental caries is relatively rare. The presumption is therefore always that the disease is secondary or symptomatic. The least attentive observer will see that it is symptomatic when, after many years of complete dental soundness, suddenly every fissure becomes a seat of caries, while the disease at the same time attacks the proximal faces of the teeth in many places. From cases like this we

may descend step by step to those wherein the most observant can not assert with confidence the nature of the disease. The pathognomonic signs of symptomatic dental caries may be stated as follows: *a*, its residue is "moist" or "leathery" in character; *b*, it is rapid in its progress; *c*, cavities are found to have originated simultaneously in different parts of the mouth. The severity of the systemic disturbing causes may be determined by noting which faces of the teeth are attacked. If the systemic cause is mild the decay will be confined to the fissured morsal surfaces, or will at most attack the buccal pits of the molars. If the systemic cause is pronounced, the proximal faces of the teeth will be attacked, perhaps also the buccal faces close to the gum margin.

7. Beyond symptomatic dental caries, using the term in its strictest sense, there is usually, after removal of the ultimate cause, some further decay of the teeth—what may not improperly be called residual decay. This is a phenomenon which we might perhaps have anticipated, *a priori*, for (apart from the probability that incipient dental caries is sometimes overlooked, to be discovered in an examination at a later date) a return of deranged salivary function to complete normality might be assumed to take time, even after full removal of the cause of the derangement; but as a fact I never thought of it till I observed it in practice, when it occurred to me, first, that I had seen it in other cases without noticing it, and then that it was a natural thing to expect.

I do not know that this residual decay has been noticed or commented on by others and therefore speak of it only from my own experience. It has appeared to me, in cases wherein I have felt able to fix the date of removal of the fundamental cause, that there was a period of some months, possibly a year or more, wherein dental caries continued to appear, though with diminished severity. The disease seemed to subside, as a rule, gradually, not instantaneously. I think it well to make a note of this both for confirmation or disproof by others, and also because residual decay if one did not expect it might prove misleading.

Having discriminated between idiopathic and symptomatic dental caries, it remains to ask on what other diseases or on what fundamental causes the symptomatic dental disease depends. Primarily, symptomatic dental caries is plainly due to disorder of the oral digestion, fault of the fluids of the mouth. Unfortunately, having said this, we have almost reached the limit of present knowledge. The sources of oral aepsia are incapable at present of being pointed out with even an approach to definiteness. We naturally first look to the other portions of the digestive tube as theoretically likely to be the over-shadowing source, by extension of derangement, of oral mal-function. But, clinically, we find in many cases that gastric or intestinal disorder is not accompanied by decay of the teeth. The oral function does not seem to sympathize universally with that of the lower portion of the digestive tract. Gastric or gastro-intestinal error (atonic dyspepsia particularly) does indeed frequently accompany the oral error, but it is probably only a joint result of a common cause. In a word, we do not find any one great or especially probable source of salivary derangement. We find merely that dental caries seems to spring from the most diverse causes with equal readiness, in fact, from almost anything which ap-

pears likely to diminish the vigor of the ultimate cells or to drain or to enfeeble any portion of the organism.

This general statement, vague as it is, presents nearly all our present knowledge on the subject of the fundamental etiology of the disease. A little definiteness may be given to the statement of causation, but only a little. We can say, cautiously, that with our present limited clinical knowledge, in male subjects not suffering from any evident organic defect, lack of good air and exercise seems the first subject of suspicion, the most probable cause. We can say that, secondarily, in these subjects, our limited experience would lead us to look to the nitrogenous diet as a fairly probable cause. For the avoidance of possible misinterpretation, I must explain that while it is the carbohydrates which, by fermentation in the mouth, directly yield the (acid) agent, which, corroding the teeth, produces dental caries, and while therefore a strictly nitrogenous diet could probably not cause dental decay because it would be devoid of acid forming material; on the other hand, the proteids, when ingested in large quantity by persons of sedentary habits, seem to give rise, probably through their effects on the greater glands, to decay-producing error of the salivary secretion; in other words an ill-advised largely-nitrogenous diet may and apparently does produce an oral or salivary condition favorable to that fermentation of carbohydrates which causes caries of the teeth.

In young men our observation would lead us to say that, even where it does not produce perceptible gastro-intestinal error, irregularity of life (sexual excess particularly) should be first suspected, it being a common, if not the most probable, cause of dental caries. In the female subject, the "organism round the uterus," the center of the organism appears to be the most suspicious point. Experience has shown that, not only pregnancy but also almost everything amiss in the female generative system, is accompanied or followed by dental decay. Caries of the teeth comes on so frequently between puberty and the menopause, ceasing when the cervical canal is rendered patulous or some other change for the better is wrought at the center of the organism, that we are amply warranted in first suspecting, in females, that the cause of our dental disease is a generative trouble.

But having said all this, we who are practicing dentistry must confess ignorance—ignorance on the one hand and inability to act satisfactorily (by reason of the burdens imposed on us by the necessary local treatment) on the other. We find that we can not yet say with certainty that any given general cause will always produce, or that any given pathologic condition will be always accompanied by caries of the teeth. We find (to take an actual case) the same person suffering at three different periods with gastric or intestinal dyspepsia or both; the first and the third attack were accompanied by dental caries (which ceased with the disappearance of the gastro-intestinal difficulty); the second attack, though it continued for two or three years at least, was not at any time accompanied by caries of the teeth. We find ourselves, in a word, when we come to the fundamental etiology and therefore to the radical treatment of dental caries, unable to answer any but the simplest questions; to solve any but the simplest problems; to cure any but the simplest cases. We

are able, certainly, sometimes, to see through a case of dental caries almost at a glance, and are able occasionally to point with ease the way to positive cure. But the cases wherein the cause of dental caries is obscure outnumber those wherein it is easily discernible. The one which I have reported for the sake of illustration may be taken as a sample of those which we daily encounter; and in cases like this, in the diagnosis of the fundamental difficulty, we who are practicing dentistry usually need assistance. Again, when the cause of the dental disease is readily perceptible, we usually need the aid of the general practitioner in its removal.

It is idle to say that he who undertakes to treat a disease should go to the bottom. As a practical fact, the dental practitioner, however thorough his understanding of the nature and the treatment of disease in general and of those extra-dental pathologic conditions with which dental diseases are connected in particular, finds that the burden of attention to local manifestations is usually all that he can bear; he must practically, as a rule, refer his patient for the radical cure of a dental difficulty dependent on a general cause, to some one else; perhaps to the special practitioner in some distant field, but usually to the general practitioner. Hitherto, owing to inattention on the part of the general practitioner to the matter which forms the subject of this paper, the reference has been made by the dentist with comparative infrequency; and when made has not always received attention. In the future it is to be hoped that it will be made more frequently, and that it will meet with a more general and a more thorough response. We who are practicing dentistry are not content to merely temporize. And if we were content to do no more than, locally, to "meet indications," our patients would not always contentedly acquiesce; for they are, some of the more intelligent at least, awaking to the fact that dental caries has more than a local meaning; and, in the interest of their general as well as of their local welfare, they are beginning to desire not merely treatment of symptoms, but cure. This, the actual cure of dental caries, we are as a rule unable to effect alone. We need the aid of those who are practicing in the general field. My aim, in this paper, has been to show that this aid can be frequently effective. And I close with an appeal for the assistance which will accomplish the end; an appeal like that of the man in the vision to the apostle: "Come over into Macedonia and help us!"

#### DISCUSSION.

DR. DUNBAR—The etiology of caries of the teeth is difficult to discuss, and I am quite ready to accept the views of the essay as to systemic influences as a general cause of decay. Original defective development of the tooth, Dr. Dean touched upon as one of the principal predisposing causes of decay. There is no question that it is an acid in some form mysteriously supplied which causes the first breach, and people moving into malarial districts are liable to many conditions which develop into loss of teeth. I heard many years ago a prominent dentist, who lived in a miasmatic district, declare that he could not save pulps when they were once diseased. So, also, the references to quinsy poisoning are certainly verified in this malarial environment. There is no question that we are on the right track for the discovery of the mysterious acid which makes the first breach in sound teeth, and opens the way for decay. We are on the verge of an important discovery to add to and supplement those of Miller, of Berlin.

DR. DEAN—I present here two teeth for inspection, and I would like an opinion as to whether the trouble with them is decay or erosion. The history is this: The teeth are

baby teeth. The child during its second summer was very much troubled with digestive difficulties—it is not fashionable to think there is any connection between such difficulties at this time and teething. The four central incisors above and below were present, but no other teeth. The upper ones presented on the points when erupted, what I thought was caries. Now I want to know what it is. The cavities approached to pulp so close that I could not attempt to fill. The four cuspids presented some appearance of erupting. I lanced over the two which were nearest to eruption, but it did not check the diarrhea. Then I cut for the others, and within twenty-four hours the digestive difficulty improved, and within a week the child had entirely recovered.

DR. L. A. TEAGUE, San Francisco—I would ask Dr. Dean why lancing was resorted to?

DR. DEAN—My belief was that the digestive difficulties were due to nervous reflex by pressure of the gum on the advancing tooth, that pressure being reflected on the papilla underneath. I lanced for the purpose of relieving the tension.

DR. TALBOT—I have had it in mind to write the same sort of a paper as this of Dr. Dean's for five or six years. We are indebted to Miller for the establishment of the relation of bacteria to the causes of caries, but we have to go outside of dental practice to find the causes of decay. I don't think the writer of the paper meant to say that the poisonous air in the home of the patient acted directly, but that it produced a neurosis which caused the lesions with which he was troubled. Neuroses, eruptive fevers, cause mal-development of the teeth and bones. It is a fact that these troubles are due to lack of tonic in the nervous system, as is nicely demonstrated in the case of the pregnant female, whose loss of teeth is due not to a lack of lime-salts in her food, but to the lack of tonic in her nervous system which prevents their proper assimilation. It is to this cause we have to look for many of the troubles which we as dentists are called on to combat.

DR. DUNBAR—It has often been said that we as a race are going to lose our teeth; that we as Americans are most prone to diseases of the teeth. Those who make these assertions cite old country districts and say they don't have these things there. It has been said that the cause of the difference is our American environment, our climate, the mixture of races, etc. They forget, in enumerating the causes of the state of affairs they describe, the circumstances under which our forefathers took up their residence here. Almost universally they had plenty of hard work to do and they raised large families, for which the mothers did all the work. Isn't it possible that a broken-down mother may transmit to the tenth or the twelfth child, especially if it is a female, her own exhausted nervous system and that that is in some cases, at least, the secret of the "poor American teeth?" Then our American haste, our constant rush for money, make us nervous and we can't transmit, under such circumstances, an unimpaired nervous system to our children. On the other side, they are more contented with their lot; here we are dissatisfied with our income and always trying to increase it. We are a neurotic people and we are begetting neurotic children. More of the difficulties against which we have to contend are due to this cause than is generally understood.

DR. A. C. HART, San Francisco—My father had good teeth; my mother poor ones. I have my father's denture. He had but one lateral incisor; I have none, but my other teeth are like his in form and quality. My brother has teeth like our mother, of poor structure, and decay progresses among them in the same way as in hers. My preceptor taught me if I found decay on one side of the mouth, to look for it in the same teeth on the other side, but while this is a good rule, it does not hold in all cases. I confess I am puzzled to account for many things, and I have to refer them to a principle which I call life-force. For instance, why is it that there are only boys born in one family and why all girls in another? I have reached the conclusion that when the man is stronger the child is apt to be a boy; when the woman is stronger, the child is generally a girl. Whichever of the parents is stronger makes the impression on the embryo which determines its sex. There are many things in which if we change the environments we change the results.

DR. TALBOT—Two points have been referred to by Dr. Dunbar and Dr. Hart upon which I want to say a word. Dr. Dunbar said there was more decay and more deformity of the teeth here than in Europe. If you take the class of people in Europe who can be fairly compared with the people here, their teeth do decay as much as here, and deformi-

ties are more prevalent and more marked there, especially among the aristocracy. I have just read a paper before the Neurological Section of the Association on this subject. The Spanish people have the most difficulty from the neuroses which produce deformities among the aristocracy of Europe. Dr. Hart brought up the point of heredity, but it is not quite fair to give a conclusion on one case only. The tenth child may be the best of all. Heredity works both ways.

DR. LUNDBERG, San Francisco—I differ from Dr. Talbot as to the condition of the teeth of the aristocracy of Europe, especially as to the part where I came from, Sweden, as I am sure they have good teeth.

DR. TALBOT—Do they not have a great deal of decay and many deformities?

DR. LUNDBERG—Not more so than here. There is no other nation of Europe where the teeth are in a more excellent condition, both in the aristocracy and the mediocracy. This is attributable to their mode of living. Their food is not so generous as here. The caries and defective teeth of Europe may be traced to gestation. You may find good teeth among people who live luxuriously, if the mothers take exercise and live on nourishing food. I don't think you can fairly say that the people of Europe have as bad teeth as the people have here.

DR. DEAN—I have asked a question as to abscess unconnected with the gingival margin. I understood Dr. Younger to say that there is always some opening or connection with the margin. I would like to ask if any one has seen a calculus unconnected with the gingival margin? (Receiving no reply, Dr. Dean said that he had specimens which seemed to be of that nature.)

## THE DISEASE OF INEBRIETY.

ITS STUDY FROM THE STANDPOINT OF THE EXPERIENCE  
OF AMERICAN PHYSICIANS OF EMINENCE WHO HAVE  
WORKED IN THIS FIELD OF RESEARCH.

BY EDWARD C. MANN, M.D.

NEW YORK CITY.

(Continued from page 853.)

SPREEING AND TIPPLING.

A not uncommon form of the tendency to inebriety is manifested, especially in young men, in whom the propensity is not fully developed. This consists in the practice of occasional "spreeing," as it is sometimes termed. This forms one of the earliest stages of the habit or attack, and may be properly termed the formative stage. It makes its appearance on occasions of rejoicing, at festivals and celebrations, on Fourth of July and during the holidays. At other times the propensity is dormant, and the individual is in no way affected by it. There is a feature in this malady, which may be properly noted in this place, and that is that in the advanced stages of the disease nothing satisfies but complete intoxication. So completely is the system under the influence of the morbid propensity, that the desire to get drunk is irresistible. No lesser degree of exhilaration or excitement answers—nothing but total obliviousness satisfies the craving propensity.

Inebriety makes its appearance as other diseases make theirs, sometimes by the fault of the individual attacked and at other times from causes over which he has no control. The propensity is quite often hereditary, and transmitted from one generation to another, in accordance with the same law by which any constitutional taint, like scrofula or tubercular disease is handed down. The law of development which, from the germ, fashions and matures an individual, and by which it is made to resemble its prototype or parents, will also in due time bring forth the defects which may have existed in a previous generation. The fact is a familiar one, that children resemble

their parents to a certain extent in mental characteristics, disposition, peculiarity of constitution, temperament and form. They are, however, not born with all these characteristics present, but as the child is developed into the man they, one after the other, make their appearance. With the development of consumption under this law we are all familiar. The child is born with a tuberculous taint. During the years of its childhood it may be well and sprightly, keep pace in growth with the most robust; but in the course of its development it reaches a point where its prototype fell into decay and died. This individual will do the same. A tendency to drunkenness will be developed under the same general law. The child will give the fairest promise, its youth will be one of innocence uncontaminated by evil influences, and the first years of manhood will be free from spot or blemish; but the critical period arrives and suddenly like a fatal cancer there is developed this morbid propensity. The man becomes changed, his appetites are aroused, his whole nature undergoes a transformation, and the prospect of his early years is blasted by drunkenness. No condition in life is exempt from such instances. We meet them everywhere, in the pulpit, on the bench, at the bar, in the church and among "all sorts and conditions of men." The period in life at which the propensity to drink is developed varies in different individuals. In some it appears in early youth, in others in the first years of manhood. The great number of young men addicted to the intemperate use of ardent spirits, who are to be found in our large cities and principal towns are examples of this class. Cases also occur where late in life the propensity first makes its appearance. Other forms of drunkenness are apparently brought on by disturbances or by great excitation of the emotional nature, or by the depressing passions, especially by grief, disappointment, mortification, shame, or loss of property, etc. In many cases the exultation following the accomplishment of some successful undertaking excites a paroxysm of inebriety. I have been led to believe that this form of emotional excitement is more frequently the immediate cause of an attack than those disturbances attended by depression of mind. The rapid accession to fortune, political distinction, success in any enterprise are very often the precursors and excitants to a course of inebriety.

The practice of tippling has heretofore been regarded not only as the ordinary but the sole cause of the development of inebriety. In fact, every case formerly was attributed to this practice. Under this view the individual was looked upon as voluntarily entering upon a habit which was sure to bring upon him a drunkard's fate. This practice has consequently been denounced as criminal, and the drinker been subjected to the severest reprobation. The courts have held that the delirium of intoxication was no excuse for violence or crime of any kind, for the condition was brought on by the voluntary act of the individual himself. It must be evident, however, that this practice is but the first manifestation of the morbid propensity, and is as much a part of methomania as is the subsequent continuous or inveterate stage. The inclination to tipple, whenever occurring, should consequently be regarded with alarm, as indicating the approach of a most serious and grave disease. Measures to arrest its advance should at once be employed, as any sanitary precautions are

taken to prevent the approach of yellow fever or cholera. It is in this stage that recovery is most likely to take place, for the disease is then only in process of formation and it is more easily thrown off. The will then has not become weakened or overpowered and the recuperative energies of the system have not been impaired.

In that form of inebriety which has been attributed to the influence of emotional disturbances, it may likewise be doubted whether these influences are the direct cause of the paroxysms; they only operate as exciting causes, and by their influence upon an organization already predisposed, weaken the power of resistance, and give favorable opportunity for the development of the disease. We have all seen individuals drawn into the vortex and swept away under disturbances of the emotions and passions, and this is no more strange than that the same causes should, in others, disorder the intellect, destroy its balance and overwhelm its faculties; occurrences which I believe are not uncommon. Do not both these conditions equally claim our sympathy and benevolent exertions? Is one *wicked* while the other is properly regarded as *unfortunate*? In all of these cases, both of methomania and insanity, we must recognize a previous predisposition to the attack. The fact that many undergo all these emotional disturbances and excitement without developing either drunkenness or derangement of mind, is conclusive that they alone are insufficient. There is a previous susceptibility to these attacks which must be regarded as unsound and morbid.

It may be remarked as to the effects of this disease upon the character of the individual, and its influence upon the moral and affective faculties, without reference to any consequent organic lesions or functional derangement, that the tendency of the practice of drinking is to obscure and destroy all the higher and nobler impulses of human nature and in prolonged cases, where the disease has wrought out its full effects, the subject of it may become completely debased and lost. Under every circumstance the effects of alcoholic indulgence are dire enough, as we all must admit, yet I believe that we have been accustomed to regard the drunkard as lost, too soon. He is not always, in fact, I believe that he will rarely be found to have become utterly abandoned. I do not believe that, even in the worst cases of inebriety, one's manhood is entirely obliterated. It is often completely overborne by the power of that terrible propensity to drink, so that no signs of its existence are put forth; but give it the opportunity, let an opening once be made in the prison house in which it is incarcerated, and the soul and the higher instincts of the man would spring forth once more, like a bird escaped from its cage, to enjoy again their freedom and a new life.

The whole subject is one of engrossing interest. Upon the medical profession will devolve the duty of treating the subject in the light of true science, in the hope and belief that, as variola has been or can be rendered harmless by vaccination, so the proper employment of remedial measures may exterminate or at least make powerless for evil, the fearful scourge of inebriety.

Elsewhere, Dr. Burr says: "It is this condition of the nervous system calling for alcoholic stimulants that is essentially the disease. This condition begins when the first inordinate desire is experienced. The

intensity of this desire, whether it be mild or virulent, does not change its character. The slightest departure from a normal appetite indicates the beginning of inebriety. The first unnatural longing for drink is essentially of the same nature as the most inveterate and uncontrollable desire. The difference is only in degree.

"The medical profession must study this subject as physiologists and pathologists, and not as moralists or reformers. The laws governing the organism, the dependence of a healthy mind upon a healthy physical condition, the transmission of normal sensations only through the media of sound nerve trunks and *vice versa*, are well determined facts, and they must be recognized and applied in the consideration of the subject of intemperance, and in explaining the unnatural phenomena of the inebriate."

The late Dr. D. G. Dodge, one of the trustees and formerly superintendent of the New York State Inebriate Asylum, at Binghamton, N. Y., some years ago expressed himself as follows, in a paper on "Inebriate Asylums and their Management": "Inebriety is a condition of the system exhibiting a class of symptoms resulting from a long-continued and excessive use of alcoholic stimulants which brings the subject to a condition he is too weak to overcome and for which he is not responsible. All stimulants containing alcohol must produce this disease; but those containing the most alcohol, when habitually taken, act more thoroughly and rapidly. It is alcohol and nothing else that is the exciting cause of the disease. Occupation has a powerful controlling influence in developing or warding off the disease. In-door life in all kinds of business is a predisposing cause, from the fact that nearly the whole force of the stimulant is concentrated and expended upon the brain and nervous system. A proper amount of out-door exercise, or labor, tends to throw off the stimulus more rapidly through the various functional operations of the system. Occupations of all kinds, mental or muscular, assist the nervous system to retard or resist the action of stimulants—other conditions being equal. Want of employment or voluntary idleness is the great nursery of this disease. The use of tobacco predisposes the system to alcoholism, as it has an effect upon the brain and nervous system similar to that of alcohol. The use of tobacco, if not prohibited, should be discouraged.

Statistics show that inebriety oftenest prevails between the ages of 30 and 45. The habit seldom culminates until 30, the subject, to this age, generally being a moderate drinker; later in life the system is unable to bear the strain of a continuous course of dissipation. Hereditary inebriety, like all transmissible diseases, gives the least hope of permanent cure and temporary relief is all that can generally be reasonably expected.

(To be continued.)

**Admirable Memorials.**—"Not storied urn or animated bust" can do that for the honoring *in perpetua* the names of departed friends, that can be done by the establishment of beds in hospitals bearing the names of the deceased. Mrs. C. M. Jeanes, of Philadelphia, has acted on this principle and has given \$10,000 to the German Hospital of that city to endow a free bed in the name of her father, Mr. John Kohler; also \$10,000 as a free bed fund to the Episcopal Hospital for her mother's remembrance, the bed to be known as the Catherine Sulgar Kohler bed.

## SOCIETY PROCEEDINGS.

### Proceedings of the First Meeting of the American Academy of Railway Surgeons.

Held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.

(Continued from page 989, Vol. XXIII.)

DR. C. K. COLE, Chief Surgeon, Montana Central Railroad, Helena, Mont., delivered the following address on

#### THE OBJECT AND AIMS OF THE AMERICAN ACADEMY OF RAILWAY SURGEONS.

The Chairman of the Committee on Permanent Organization has placed me on the program for an address on the objects and aims of the American Academy of Railway Surgeons. I confess, at the outset, that the subject has not received at my hands the consideration its importance demands. If my statements are too brief, or too lengthy, too enthusiastic or too scant in facts, the fault may justly be charged to my friend, Dr. Reed, whose large experience should have taught him more discernment than to have selected me for such a task.

We have met to consider the advisability of organizing a Society of Railway Surgeons, which shall be cosmopolitan in character, in the sense of including representative and active men from every section of the United States, and yet whose distinctive features shall include a strictly limited membership; the limitation not applying to any particular class or grade of railway surgeons, but to numbers only. A society which shall have for its prime object the promotion of the study of railway surgery as a special and important branch of the surgical art. We have not met to decry the efforts of others in this field, nor in any wise to antagonize any individual, or any set of men, in any department of medicine whatsoever. This statement seems warranted at this time, in view of the fact that it has been sought to show that our motives were not free from prejudice and bias. In this connection I may be pardoned for suggesting, that if any of us in this assembly are possessed of any other desire in connection with this first meeting than that of the development of a higher order of railway surgery, such person would best subserve the interests of the proposed organization by withdrawing before a permanent organization is effected.

However widely divergent our views may be as to methods, I assume that we are agreed that there is urgent need of steps looking to the placing of railway surgery on a higher plane than it has hitherto occupied. A facetious critic in a recent journal article, entitled, "The Evolution of the Railway Surgeon," undertook to show the folly and unwisdom of claiming any special skill or requirements in the practice of railway surgery, or the necessity for organization on the part of those engaged in this work; the experience of those present here to-day, indeed, the very fact of your presence here, is a sufficient refutation of this idea.

How best to effect an organization which shall successfully accomplish the objects in view, demands our earnest and most careful consideration at this time. During a number of years past, various plans of organization have been discussed by those more or less interested in this work. These plans have been so numerous and varied, that it is impossible in the time at my disposal to rehearse them fully and in detail. Among them, however, may be mentioned: 1, a large popular body, made up of all those engaged in the practice of railway surgery in the United States, the Canadas and Mexico; 2, a delegatory body whose members should be annually elected from State or district societies; 3, representation in a central National society by railway systems, by States or by districts, which should each include

six to twelve States. In addition it has been suggested that separate organizations be had for Local, Division and Chief Surgeons. These and other plans have each had their day and advocates, until comparatively recently, when the consensus of opinion seemed to indicate that a society with a limited membership and composed of experienced railway surgeons, of whatever grade, and who have demonstrated their qualifications for, as well as their abiding interest in railway surgery, should be formed. Generally speaking the railway managers and legal counsel, have heartily approved the plan as herein outlined, so that it remains for us to organize a society that will prove a permanently influential factor in the advancement and upbuilding of this important department of our great railway corporations.

This organization will prove useful and effective, exactly in proportion as its founders exercise care to eliminate, at the outset, such objectionable features as have been proven in experience to be dangerous. We must agree in advance that our first object is honest effort in the interest of science, so that those who look to us and depend upon us will, perforce, applaud and second our efforts, as improved methods and better results shall impress them with our sincerity of purpose. We must agree upon a plan or basis of organization which will most nearly meet, not only the conditions at present existing, but also such exigencies as are likely to arise in the future. We must agree to avoid strenuously those elements which experience has shown us to be disastrous. We must, in brief, agree that there exists a genuine necessity for such an organization as it is proposed to effect at this time. If we can not agree upon these various points, and in addition that we will each, to the best of his ability, devote time and energy now and hereafter, to the erection and maintenance of an harmonious structure for the purposes intended, it were better that we should at once separate and leave to others a task of such momentous importance.

The eyes of the railroad world will be upon us; our action will be scrutinized and perhaps our motives impugned by those who do not wish us well. We must be prepared to meet certain unjust criticisms and predictions of failure on the part of those who do not love us or our cause. We must assure ourselves of the propriety of our motives and the rectitude of our course, so that our honesty of purpose may appear to the public in such a manner as to serve as a bulwark of defense against those who seek our discomfiture by inveighing against us.

It has occurred to me to supplement these remarks by reading a draft of a Constitution and By-Laws which will be submitted for your consideration some time during the session, and with the permission of the President, and if no one objects, I will proceed to read.

[The proposed Constitution was then read, and will be published hereafter as adopted.—ED.]

DR. W. J. GALBRAITH, Chief Surgeon, Union Pacific Railroad, Omaha, Neb., delivered the following address on

#### REASONS FOR THE ORGANIZATION OF THE AMERICAN ACADEMY OF RAILWAY SURGEONS.

It is my aim to present to this honorable and distinguished body of railway surgeons, some of the practical necessities and reasons for the organization of the American Academy of Railway Surgeons—an organization, born, so to speak, of the advancement of a scientific period wherein, in my opinion, we are in duty bound to combine our knowledge of modern railway surgery, as well as our experience and mechanical ingenuity, in this our special field of the surgical art, and thus advance and promote the standard of railway surgery in this country, and at the same time offer better protection, in times of wrecks and serious accidents, to the employe, the passenger and the company we represent.

I shall not take up your time by going into and defining

the many detailed reasons for the organization of this Academy, but on the contrary will attempt to point out some of the evil influences we must at all times guard against to insure its success, and especially at our regular meetings. I feel confident that unless we observe the proper course of discipline and keep harmony in view, it will be but a short time—yes, a very short time, until the primary objects of this organization will have been lost sight of, and the Academy fall into disrepute.

The reasons for this organization are the proper demands of our companies for us at all times, regardless of political and personal motives, to consider and study the scientific principles of how best to render surgical aid to the special classes of cases that fall into our hands by virtue of the positions we occupy as railway surgeons. Moreover it would be a fruitless task to attempt to demonstrate to you the many ways that we can assist in elevating the science of railway surgery, as well as how best to consider the many perplexing medico-legal problems that are frequently referred to us by the great corporations we represent, as well as in times of legal strife and trials, when we are summoned to appear in court as surgical experts. The great difficulty of establishing facts in personal injury propositions are well known to every judge. Our experience should map out to us the loyal and proper course to pursue, in order to protect our companies from fraud and deception. It is useless for me to dwell upon the necessity of the proper discussion of this monstrous subject, but suffice it to say, that it is one of the principal reasons for the organization of this Academy.

This Academy fully appreciates the great importance of the many complications of railway surgery and the scientific requirements of a better knowledge of the same.

It affords me great pleasure to announce, not only to the managers of railroads but to the general public as well, that this Association fully appreciates the vast field that is open to it for investigation, and by our combined efforts and constant research we shall hope to elevate our calling. With so many scientific problems before us for investigation, why should we invoke the disgust of our managers, by making useless and foolhardy recommendations as to the proper automatic car couplers to be used, or indeed to attempt to promulgate legislation looking to the passage of laws compelling all railroads to equip their rolling stock with uniform safety appliances. Action of this kind might be proper and indeed humane, but I do not deem it within the province of this organization. Nor should this organization, at this time, consider such sanitary problems as the reconstruction of the modern Pullman car, by doing away with the present elaborate upholstery and draping; or recommending that cars be especially constructed for the transporting of consumptives and attached to all trans-continental trains in order that healthy passengers might not be exposed to the contagion or infection of tuberculosis and kindred diseases. Nor can we consistently recommend that hospital cars be maintained at all division terminals of our large railroad systems for use in times of emergency. The extreme impracticability of these and many other schemes that have been advocated by some of the younger and less experienced railway surgeons in the past, is fully appreciated by this body of surgeons. Pause, for one moment, and consider the enormous expense that would be entailed by equipping with hospital cars a single railroad like the Union Pacific.

We should not lose sight of the fact that our railroads are managed by the most able men, in their special avocations, the country affords; and that these managers have placed at the heads of the various departments of their roads, men of corresponding ability. It is the business of heads of mechanical departments to investigate the merits and de-

merits of whatever safety or other devices are offered, and make their recommendations to the general manager. It would be absurd then, I say, for this organization of scientific men, to mix itself up in mechanical problems that should be left alone to the mechanical and operating departments of our railroads.

One of our most prominent railroad managers, in conversation with me, a few days ago, commented most favorably upon the business-like appearance of our program for this meeting, and suggested that it would be wise to send a copy of it, as well as of all other matter pertaining to the Association, to every manager in the country, in order that they might see and know what we are doing, and especially familiarize themselves with the manner and methods employed by us in promoting this important adjunct to the modern operation of railroads. I can assure you it would give me great pleasure to have with us here to-day, all, or at least a majority of the prominent railroad managers of this country, that they might see and appreciate to a small extent, at least, the zeal that is manifested by this gathering of earnest intelligent surgeons, to promote by unified research, the important specialty of railway surgery. I am glad to state that Dr. Reed will be able to give you some very surprising information concerning the railroads in this country, as well as in the Dominion of Canada and Republic of Mexico, who have expressed themselves through their general managers as being highly in favor of an organization based upon such meritorious principles as are declared by this Academy. And also, that we are encouraged and supported by the most eminent contributors to the literature of railway surgery of our times. This is certainly a very strong incentive for us to use our best endeavors to make the very most of this organization from a scientific standpoint, and truly earn that exalted motto of the Academy, "The higher the order of railway surgery the greater the protection to the employe, the passenger and the company." For what does this encouragement mean? Does it mean that we have, by false pretenses and deception invoked the support of these leading railroad men? or, does it mean that these men recognize the necessity of an organization of this kind for scientific purposes and not for the purpose of affording hundreds of surgeons the opportunity of requesting transportation for themselves, families and friends to enable them to gratify their junketing and pleasure seeking proclivities.

The future of this Academy must be apparent to every one within hearing of my voice, when we consider that this gathering together of so many eminent surgeons, is but the fruition of a few weeks' work of our committee. Certainly, it is evident that the great sheet anchor of our success (the managers) have seen and appreciated the untold benefits that may be derived from the conscientious work of an organization like the American Academy of Railway Surgeons in the working out of scientific problems growing out of the operation of railroads.

The practical feature of this Academy in limiting its membership to only active workers and writers has received several very commendable comments from general managers; they agree with us that a smaller number of active workers will accomplish much more good than a large number of lookers on. That this Academy will advance the standing and science of railroad surgery is a certainty. It requires but a glance about this hall to behold many eminent surgeons, who, by their standing and support of the railroad they represent have this day founded one of the most respected and honorable surgical societies in this country. The character of our program proves very conclusively the distinction I have given you; its business-like expression having superseded notices of excursions and junketing trips,

which have been the great drawing cards heretofore.

In conclusion, I desire to impress upon your minds the great importance of a loyal spirit toward the company you represent, as well as its employes. Secure full and accurate statements of facts in all cases of accidents. Avoid useless recommendations to your managers; and more particularly should we have a care not to allow our political ambitions or desires for self-aggrandizement to dominate our better judgment, but constantly bear in mind that this Academy is organized for the sole and express purpose of promoting our special scientific work, first, last and all the time, and thereby demonstrate to our companies its practical usefulness.

#### A SYMPOSIUM ON PERMANENT ORGANIZATION.

was given by DR. HARVEY REED, Consulting Surgeon, B. & O. Railroad, Columbus, Ohio.

In the permanent organization of any society or association, every factor effected by such an organization should be carefully considered. Among some of these factors may be mentioned: 1, objects; 2, the methods of accomplishing the desired end; 3, those effected either directly or indirectly by such an organization.

In the address presented by Dr. Cole, you have learned that the objects of the American Academy of Railway Surgeons are: 1, the clinical and scientific study of railway surgery; 2, the careful consideration of the medico-legal questions arising out of the railway service; 3, the consideration of such sanitary and hygienic problems as may effect directly or indirectly the railway companies.

No one can deny the practical importance of the objects proposed by the Academy, and that the carrying out of the same will result in "the higher order of railway surgery," which guarantees a corresponding protection to the employe, passenger and company.

The railway service of modern times has gradually changed from an amorphous condition to that of crystallized precision, and depends for its success upon system and exactness in all the details of the service.

It has been found necessary to have a head to every department, and those employed in each department should be well qualified for the duties devolving upon them in carrying out the work assigned to them. The better they are qualified, the better service they can render the company, and the better service rendered the company the greater the earning capacity is increased on the one hand, and the less expenditures on the other.

#### I.—THE DESIRED END OF ORGANIZATION.

It has seemed strange, and we might almost say paradoxical, that the surgical service should be among the last departments to undergo crystallization. Yet it is an undeniable fact that the progressive railway companies of this country have discovered that the maintenance of a well-organized surgical service is a valuable department to the company. They have learned that while it does not represent earnings, it protects earnings after they are secured and, as the old adage goes, a dollar saved is equivalent to a dollar earned.

#### II.—THE METHOD OF ACCOMPLISHING THE DESIRED END.

It is not only necessary for the Academy to have grand practical objects in view, but it is equally important that the methods adopted for carrying out these objects should be carefully, conscientiously and impartially considered. In maturing plans for the permanent organization of the Academy, it has not only been advised by many of the leading surgeons who have had long experience in the service, but recommended by many of the managers, that the Academy be limited in numbers and the same be confined to surgeons of practical ability, either as experienced surgeons or eminent

observers and writers on railway surgery, forensic medicine or sanitary science.

It has long been demonstrated, that in order to accomplish the greatest amount of work in a certain direction, it is necessary to limit the number who undertake the work and make the responsibility on each one proportionately greater. For instance, the railway companies do the large bulk of their important business through their general managers, who not only have experience but are held responsible for grave trusts that involve millions of dollars, which if left to the stockholders to manipulate would result in financial disaster. For this reason the railway management argues, that in order for the proposed Academy to accomplish the greatest amount of benefit to the company they represent, it can be done best by an association, such as is proposed, of a limited number of energetic practical workers who will meet from year to year, to consider and discuss the many important problems that are daily manifesting themselves in the general surgical service of the companies they represent.

The question as to how the membership of the Academy should be selected and maintained was one of no small importance, and, I can assure you, one which was not easily solved. At first thought, a delegatory system would seem to strike the mind most favorably, but when we come to consider this system in its details, the question arose as to who should select the delegates. If this could be settled satisfactorily, then a still greater obstacle presented itself, and that was the continual change of membership of the Academy from year to year.

For example, if we were to base our membership upon one delegate for every ten railway surgeons in the United States, we would at once have an eligible membership of about five hundred. We could not expect the same delegate to return from year to year, and if the company, or chief surgeon, or local surgeons from which the delegates are selected, were to attempt to act impartially and give each of their staff an opportunity to attend an annual meeting, you will at once see that with each annual meeting a new set of delegates would appear and that, under this system a delegate would only be able to attend a meeting of this character once every ten years. This being a fact, you can readily see how it would interfere with the interest on the part of the delegates, saying nothing about their ability to accomplish the highest scientific work possible.

After discussing this question in all its phases, your committee thought best to select a nucleus for the Academy, consisting of surgeons who were believed to be worthy and well qualified in carrying out the arduous task proposed by the new organization, and that in doing so they should be made permanent members, not only in order that they would have a permanent interest, but that it might enable them to accumulate knowledge which, with each year, would increase their value, not only to the Academy but to the railways they represent and railway surgery at large. Firmly believing that this plan will render the best service, a skeleton constitution which we have already referred to has been prepared with this idea in view, and it is left to you, gentlemen, to say what the limit of membership shall be and to fix the standard of admission.

### III.—THOSE AFFECTED EITHER DIRECTLY OR INDIRECTLY BY SUCH AN ORGANIZATION.

In adopting the fundamental laws of the proposed Academy, we must not be unmindful of those who will be affected by the same. We must remember that not only those who may be selected as Fellows of the Academy will be benefited or injured by our fundamental laws, but our fellow-surgeons and co-laborers, as well as the management of the railroads, will be affected for good or evil by the constitution which

we may adopt. Our standard of admission should be high and the limit of our membership low. Every candidate who applies for admission should be carefully scrutinized before taken into fellowship. This would of necessity require us to take into consideration, not only what benefit the admission of such a candidate would exert on the Academy, but to what extent he would benefit the railroads which we are supposed to serve to the best of our ability in the capacity of railway surgeons.

Our fundamental laws should be of such a character as to exclude all actual drones and simple ornaments from our midst. It should encourage the admission of honest workers who will not only be willing but eager to meet with the Academy from year to year, and assume any duties that may be assigned them which they may be capable of carrying out. We must remember in the adoption of our constitution that we are on trial and that our success, our prosperity, yea, our right to exist, will depend on the character of our work and the fruits of our labors. While sociability should contribute its benefits to the members of our Academy, our highest aim, first, last and all the time, should be the constant advancement of railway surgery by a continued endeavor to simplify its technique and solve its mysteries and thereby contribute a liberal benefit to the companies we represent.

We trust that the few hints we have thrown out in this symposium will aid the members of the Academy in adopting a constitution which will not only be simple, but practical, and which will contain the greatest number of good with the least number of objectionable features possible, and that in the consideration and adoption of these laws each Fellow will keep in view the fact that "the higher the order of railway surgery, the greater the protection to the employe, the passenger and the company."

DR. W. H. ELLIOTT, Chief Surgeon, Georgia Central Railroad, Savannah, Ga., who was on the program to open the discussion on the three previous papers, being detained by a railroad wreck, the discussion of these papers was postponed until later in the session. On the arrival of Dr. Elliott, the matter was again referred to by the following remarks:

#### *Mr. President and Fellows of the Academy:*

The objects and aims of this Academy should be to advance the science of railway surgery. True devotion to the attainment of knowledge and its successful application in the practice of our art, are the only means by which we can obtain this end. Devotion to science must be paramount to the gratification of personal ambition. Honors in this Academy must come unsought.

Nothing must be said or done which will reflect upon or injure the National Association of Railway Surgeons, because we are still members of that body and fellow-members in the medical profession, and the injury of one is the injury of all. No discussion with the National Association or its members in regard to this Academy is necessary or desirable. Arguments might become heated, and while failing to convince, would most probably result in injury to the cause of railway surgery. A success of the Academy at the expense of the National Association would be temporary only, and would finally end in lowering the esteem in which the Academy and railway surgery is held.

Nothing must be done in the Academy which is not open to inspection or which is in any way calculated to make a false impression. Nothing can succeed in the long run but noble and high aims founded upon truth and justice. Our motto calls on us to be true to our profession, to our patients, and to the railway companies we serve.

"This above all; to thine own self be true;  
And it must follow, as the night the day,  
Thou canst not then be false to any man."

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
NO. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, JANUARY 5, 1895.

THE ALLEGED BACILLUS OF BILIOUS FEVER.

The medical world has heard but little of the bacillus of bilious fever. The *éclat* which attended the recognition of the spirillum of cholera and the bacillus of tuberculosis was not extended to the recent announcement of DR. DOMINGOS FRIERE, of a bacillus similar to that of TOMMASSI-CRUDELI in the bilious fevers of hot climates. Yet locally, in the place of its origin, this announcement created such a disturbance in the medical atmosphere as to agitate not only the professional but the daily press; and this because in addition to the intrinsic importance of the alleged discovery, the question was incidentally raised of the value of FREIRE's inoculations with attenuated cultures in immunizing against yellow fever. Many letters were published, copies of which are now before us, from which we outline in a suggestive way the manner in which the announcement was received in Rio de Janeiro. It appears from these that PROFESSOR FREIRE has found the plasmodium of LAFERAN in some cases of malarial disease, but regards this organism as a result in the blood of the action of the bacillus which he has just discovered.

Three medical men, two of them former pupils of PROFESSOR FREIRE, and all of them at one time his disciples and admirers, visited his institute to verify the existence of the bacillus. They were DRS. CHAPOT-PREVOST, OTTONI and FAJARDO, the first, Professor of Histology of the Faculty of Medicine of Rio de Janeiro, the second his assistant, and the third, physician to the yellow fever hospital. As a result of their visit, DR. CARL SEIDL, Director of the San Sebastian Fever Hospital, published an invitation to PROFESSOR FREIRE to submit his cultures and methods

to a commission of competent men to be named by the medical faculty, stating that men of this kind whose competency and impartiality were above suspicion were as easily to be found in Brazil as in Europe, and charging him as follows:

1. That he had no pure culture of the alleged bacillus in his laboratory.

2. That to mitigate the disappointment of his visitors he allowed them to examine a microscopic preparation (with a cracked cover-glass) from an impure culture.

3. That a kidney slice from an infected guinea pig, referred to in his publication as showing the bacillus, presented only purple stained nuclei of cells of connective tissue which had been christened bacilli.

4. That his assistants vaccinated with a culture which he, FREIRE, said *ought* to be pure.

5. That on examining this culture it was found that the defects of the cover-glass had been considered by him as qualities of a pure culture; and that below this was a mixture of sprouts and infusoria, which mixture served for his vaccinations.

PROFESSOR FREIRE in reply held his position to be established by his visitors' own acknowledgment that they had seen a culture; that on account of the technique he had employed (described by CORNIL) the purple objects in the kidney slice could be nothing but bacilli; he laughed to scorn the idea that flaws in the cover-glass had been photographed as bacilli; but made no reference to the invitation to submit his work to a commission. CHAPOT-PREVOST, who is a pupil of EHRLICH of Berlin, retorted that neither he nor his friends had seen a *pure* culture, and that the students in his histologic class will show to any one in the normal kidney of the guinea pig, purple stained nuclei obtained by the processes used by FREIRE in preparing his kidney section; and again and again is the Professor urged to demonstrate the existence of the bacillus before a selected committee, so that in the sixteenth letter of the series now before us he at last disposes of the invitation after this manner: "I am not his pupil to be at his caprice nor is he my superintendent. It would be against my dignity as a professor of a faculty to be giving explanations to whoever demands them, about an elementary manipulation of a bacteriologic process which every apprentice ought to know."

Naturally, in the course of this discussion, the participants digressed to the micrococcus xanthogenicus. FREIRE attributes all the opposition to his discoveries to a clique who, not content with spreading their detractions in Brazil, have endeavored to plant a center of opposition to him in Paris; and he refers to his statistics as establishing the value of the "vaccinations" for yellow fever. SEIDL replies that these vaccinations have been in progress since 1883 and yellow fever continues, becoming year by year

more formidable and destructive, instead of being gradually stamped out as was prophesied by FREIRE. Statistics will never convince the bacteriologists of the world, the medical fraternity of Brazil, nor the public, of the value of these vaccinations. "For where is the physician, where is the intelligent man in this town, who does not know cases and cases in which said vaccination was not only useless but perhaps harmful because it caused a false confidence?" In the laboratories of Paris, Vienna and Berlin are long series of pathogenic germs, some only recently announced, yet there is no culture of the xanthococcus which has been discovered for so many years and put to practical account in Rio. OTTONI challenges PROFESSOR FREIRE to name one laboratory, not his own, in which the xanthococcus has been verified as the cause of yellow fever; and the suggestion is made that since we have waited so long for the verification of this microbe we may have to wait a considerable time for a pure culture of the bacillus of bilious fever.

The last letter of the series, number twenty, by DR. SEIDL, closes with this reference to the invitation for an investigation by competent men: "And the committee of experts will wait for the Greek Calends?"

#### FLECHSIG'S TREATMENT OF EPILEPSY.

The treatment of epilepsy has always been surrounded with many difficulties. The disease itself is symptomatic, presenting a most varied pathology, from that of a functional neurosis to those graver conditions involving organic degeneration. Such being the case it is apparent that any method of treatment must have only a limited range of application. Undoubtedly, the greatest successes are reached in this disease along those lines which improve the general nutrition of the body and thus render more stable the nerve cells concerned in the production of the attacks. There is no disease which more certainly affirms that we should beware of the single remedy, or of one method. While the bromid treatment is perhaps more generally successful than any other, yet it can not be followed as a routine practice and it is not adapted to more than one-half of the cases that are actually met with in practice.

Recently, COLLINS (*Medical Record*, Sept. 22, 1894) has studied the method of FLECHSIG in the treatment of some forty cases with, he claims, excellent results. The method consists in the administration of opium beginning with a dose of 1 grain after each meal, and increasing until 10 to 12 grains are given during the course of the day. This treatment is persisted in for about six weeks and is not usually followed by any reduction in the number of the attacks. Some patients complain of the effects of the opium but this is overcome to a great extent if the patient takes

a good deal of physical exercise, and free catharsis is employed. At the end of six weeks the opium is abruptly discontinued and comparatively large doses of the bromids are given. This in a majority of instances is followed by a marked diminution in the number and severity of the attacks, and improvement in the general mental condition of the patient. The bromids are then rapidly diminished until a small dose is reached, or else they are discontinued altogether according to the condition of the patient.

Some of the cases reported by COLLINS were those of epileptics who had been under the bromid treatment with very unpleasant results, but after the use of the opium the bromids were well borne. The method seems to give the best results in those severe cases dependent upon organic changes in the brain and vessel walls, precisely those cases in which other methods have so signally failed. A number of cases of idiopathic epilepsy have done exceedingly well under this treatment, but not so much is to be looked for in this class of cases.

---

#### REVIVAL OF A SIXTEENTH CENTURY SUPERSTITION.

The fasting girl and trance states furnish the greater number of medical newspaper sensations, but this was varied on December 26 by the appearance of an article in the *Chicago Evening Post*, under the following startling headline: "He resembles the image." The article which is a dispatch from Jamestown, N. Y., goes on to say that one, GEORGE W. DEPEW, has been arrested for the murder of MRS. WINSLOW SHEARMAN and her daughter MRS. CLINTON. He has been identified by his resemblance to an image of a man seen in MRS. SHEARMAN'S eye. The dispatch then goes on to state that the discussion over the possibility of identifying a murderer by the image left on the retina of the victim's eye has been revived with great intensity. Versimilitude is given the narrative by the statement that, "those who saw the image before it was blurred by removal of the eye from the socket, remember the image so distinctly that they could identify the general outlines of the man's figure from it and the half profile revealed in the image. Before the removal of the eye the image was sharply defined." If there is still a lingering doubt in any one's mind regarding this statement it would be swept away by the following: "Even the wrinkles in the clothing were plainly seen by the aid of the microscope."

All through the Middle Ages there was a belief that the eye of a murdered person contained an indelible impression of the last scene upon which he looked. In the jurisprudence of that time there are cases recorded of conviction upon such evidence. It, however, was never received with as great favor as was the touching of the dead body by the suspected

person, to learn if the wounds would bleed afresh, in which case guilt was held to be fully established. The theological element figured in this latter test, just as it did in that of the ordeal of battle.

It must be very comforting, in these *fin de siècle* days, to those who have an abiding faith in the good old times of the fathers, to have a story of this kind follow upon the heels of an outbreak of "hypnotism" in a Wisconsin town, allied in many respects to the famous witchcraft episode at Salem.

---

#### THE PLEA OF HYPNOTISM IN CRIMINAL CASES.

Undesirable effects of a little dangerous information on medical subjects on the part of the public are frequent enough, and indeed too common to usually call for special remark. When, however, a wave of mental aberration seems to be going over the country, and on a subject that comes especially within the purview of a medical journal, it would be unpardonable to let it pass unnoticed, the more so when the evil is in part due to the encouragement given by an unscientific credulity on the part of members of our profession, regular and otherwise.

Within the past few weeks the plea of irresponsibility for capital offenses on account of hypnotic influence, has been raised in two prominent instances, and in at least one other case it has been successful. This is not a new mode of defense. It formed one of the most prominent features of the celebrated EYRAUD case, tried in France two or three years ago, but the homicide McDONALD, of Wichita, Kan., is apparently the first one who has successfully availed himself of it. The precedent has been set, and the possibilities for this plea in the future are indefinite.

While one may admit that a somnambulist *may* irresponsibly commit a homicide, and that the actual condition of hypnotism is a sort of induced somnambulism, the possibilities of miscarriages of justice in applying this to criminal jurisprudence are too great to be ignored. There is not merely the chance of a murderer escaping by this plea, but there is even a greater possible danger to innocent parties from false accusation. This is well illustrated in the PICKIN case in Wisconsin, now exciting so much popular interest. Whether or not there is any basis of fact in the charges, the range it opens to hysterical accusation is sufficiently obvious.

The responsibility of the regular medical profession in this matter is a very large one. It is not probable that any man can be convicted or acquitted on a plea of hypnotism without the testimony of physicians, and how many are there who have well founded and scientific opinions on these subjects? It is to be feared that the number is by no means so great as it should be, and that the credit of medical testimony will suffer in consequence. The views in

regard to hypnotism of some men who ought to know better, are wild enough; with some it has reached the evil eminence of being a fad, and there seems to be no limit to their credulity.

It is astonishing how little real advance there has been in our discussions of this subject, and how sensible were the views of many of the earlier alienists of this country and abroad in regard to it. One need only read a work published in the early forties by Dr. J. W. GALT, of Virginia, and which, with the exception of RUSH's work, was the earliest important contribution to psychiatry in this country, to be convinced of this fact. The later literature of hypnotism, with the exception of a few important contributions, is to a great extent a waste of human effort and largely a monument of human credulity.

The object of these remarks is to call attention to the medico-legal importance that may become attached to the subject, and to emphasize the need of a proper cautious scientific spirit on the part of our profession in dealing with it. It has other phases perhaps not less important in their way, such for example as the effect on public health of the practices now prevalent; but that, as MR. KIPLING says, is another story, and may be dealt with hereafter.

---

#### SMALLPOX IN 1894.

After all the space given to the subject in the public press, concerning the "ravages of the loathsome pestilence," it appears that there were only about ten thousand cases of smallpox, with not to exceed three thousand deaths, in the United States during 1894. Compared with the constant mortality from consumption, pneumonia, diphtheria and other contagious or infectious diseases—more or less preventable—it is apparent that smallpox has lost its epidemiologic significance for this country almost as fully as has Asiatic cholera or yellow fever. There may from time to time occur an outbreak of either of these latter diseases; but there is reason to believe that the terrors which cholera caused during the middle third of the century, and yellow fever for more than a hundred years, will never again be repeated.

The prevalence of smallpox in 1894 has been pithily called "the lesson of neglected vaccination." But while this is, in a certain obvious meaning, an apt characterization, there is also an optimistic lesson in the figures which should not be overlooked. One hundred years ago (JOHN SIMON) there were 96 deaths from smallpox out of every 1,000 deaths from all causes. At our average annual death rate (J. S. BILLINGS) of 18 per 1,000 there were 1,170,000 deaths from all causes last year in a population of 65,000,000. One hundred years ago, therefore, we should have had 12,300 deaths from smallpox last year instead of less than three thousand.

That this latter number is wholly unnecessary is true; but the difference between what is and what might have been, but for JENNER, is another laurel for his centenary next year.

## CORRESPONDENCE.

### The Erysipelas Toxins—A Reply to the Editorial of Dec. 15, 1894.

NEW YORK, Dec. 20, 1894.

To the Editor:—My attention has been called to your recent editorial upon the "Failure of the Erysipelas Toxins." Coming so soon after a previous editorial upon the *success* of the toxins, I am somewhat surprised, not so much at the radical change of views, as at the change having been allowed to take place without a more careful inquiry as to the present status of the treatment and a more critical analysis of the evidence presented.

The statement is made in your editorial: "There is no longer much question of the entire failure of the toxin injections as a cure for sarcomata and malignant growths. During the past six months the alleged remedy has been faithfully tried by many surgeons, but so far not a single well authenticated case of recovery has been reported, so far as our reading has extended, and the personal experience of surgeons of our acquaintance with whom we have conversed, demonstrates that in all cases in which they have tried the erysipelas toxin the result was no improvement." It is further stated: "We should not accept as conclusive, reported cures by any investigator, no matter how prominent. We should demand that these cases be corroborated by other observers making investigations independently."

Fortunately, there is no issue between the editor and myself as to this latter statement; and only such evidence as will stand the rigid tests of scientific demonstration will be considered. This whole dispute, then, resolves itself into the simple question of fact, *Does or does not* such evidence exist? I presume the writer of the editorial used the term, "erysipelas toxins," in short for the toxins of erysipelas and bacillus prodigiosus. As I was the first to propose and to carry out this method of treatment for sarcoma, and as I am the only one who has used this method in any large series of cases, it would seem that my experience, stretching over a period of more than three years, ought to have as much weight in determining its value, as the "personal experience of surgeons of the editor's acquaintance," whose observations cover a period of less than six months.

In my paper on this subject presented before the American Surgical Association at Washington, May 31, 1894, I reported the results of twenty-five cases of inoperable sarcoma treated with the mixed toxins. Of these cases, six were successful up to that time. Since that time I have treated thirteen other cases of inoperable sarcoma, with the result of now having ten cases out of a total of less than forty in which there is good reason to hope for permanent cure. These results were reported in a recent paper before the New York Academy of Medicine, Nov. 15, 1894, and will soon be published in detail in the *New York Medical Record*. None of the six successful cases reported at Washington, six months ago, have shown any tendency to relapse. One of my cases has gone three and one-half years. This was a twice recurrent sarcoma of the neck and tonsil, with the patient in a most desperate condition, with no chance of living more than a few months. He had been operated upon by Professor Duranti, of Rome, and Dr. Bull, of New York. The microscopic examination was made by

Dr. Farquhar Ferguson, Pathologist to the New York Hospital, and he was frequently seen during the treatment by Dr. Wm. T. Bull, Professor of Surgery of Columbia College.

Two other very extensive inoperable cases have now gone nearly two years without recurrence. Both cases were treated at the New York Cancer Hospital, and the diagnosis confirmed not only by Dr. Bull and other surgeons but by careful microscopic examination by the leading pathologists of this city. Both of these cases were presented Nov. 15, 1894, at the Academy of Medicine, in perfect health. Another case that has now gone more than one year, a large inoperable sarcoma of the abdominal wall, was sent to me by Dr. Maurice H. Richardson, of Boston. I will quote Dr. Richardson's own words taken from the discussion and found in the *Transactions of the American Surgical Association*, 1894: "In this case there was no doubt, according to accepted methods of diagnosis, that the woman had a malignant and necessarily fatal disease. The mass filled the right lower quadrant of the abdomen. When I operated I first incised in the median line and came down on the tumor. I then made an incision in the lateral region with the same result. There was nothing to be done surgically. I took out a section and had it examined. It was pronounced sarcoma. The patient was sent to New York in October. In May there was not the slightest sign that could be detected. Unless the diagnosis was entirely wrong; unless the history, gross appearances and microscopic examination were entirely wrong, there was a case that would have died sooner or later." I will add that the microscopic examination was made by Dr. Whitney, Professor at the Harvard Medical School, whose reputation as a pathologist and microscopist ought to be sufficient guarantee of the accuracy of the diagnosis.

Space will not permit me to go further into detail, but in all of my cases the diagnosis was not only established by eminent surgeons, but confirmed by microscopic examinations of competent pathologists. Such evidence as this I claim to be *scientific*, in the strictest sense, and it can not be lightly dismissed as inconclusive because reported by a "single investigator."

In closing, I will say that the editor's demand that "these cures be corroborated by other observers" has already been completely met. The report of a very extensive sarcoma of the palate and pharynx, successfully treated by Dr. Walter B. Johnson, of Paterson, N. J., may be found in the *New York Medical Record* of Nov. 15, 1894, and four other successful cases in the hands of different surgeons throughout the country who used the mixed toxins, prepared and made under my direction (from cultures originally obtained from a fatal case) will shortly appear, with the publication of my paper.

In my previous paper (*loc. cit.*) I stated that cultures obtained from any but a very virulent case of erysipelas were of little value, and furthermore that all of my successful cases had been treated with toxins made from cultures obtained from a fatal case of erysipelas. Fully recognizing the importance of caution and conservatism in a matter of such grave import, I refrained from publishing my results, not only until I had a sufficient number of cases, the diagnosis of which was beyond question, but until sufficient time had elapsed to prove the permanency of the cure.

That a few physicians, in a very limited number of cases, with indifferent preparations of the toxins, have failed to obtain good results will not, I am sure, have great weight in the minds of the scientific portion of the profession, in determining the failure or success of this method of treatment of sarcoma.

Very truly yours,

WILLIAM B. COLEY, M.D.

## The Treatment vs. the Abortion of Typhoid Fever.

YOUNGSTOWN, OHIO, Dec. 24, 1894.

To the Editor:—During the past year you have published four papers on typhoid fever, which I had read before the Mississippi Valley Medical, the AMERICAN MEDICAL and the Mahoning County Medical Societies. Those papers were all written for one object,—to prove that typhoid fever can be aborted—a difficult enough task surely; without wasting much time in giving details of a treatment which I did not suppose many would care to try until very conclusive evidence of its efficacy had been presented, but although, some physicians have secured most brilliant results from the treatment by relying on these published directions as their only guide, I fully recognize their inadequacy and have always intended to write a treatise on the abortive treatment of typhoid fever, as soon as there seemed to be a demand for it.

Since the publication of my first paper in February last, I have received many letters asking for exact details of my method of aborting typhoid fever, but I do not find the name of Dr. W. S. Caldwell of Freeport, Ill. He must therefore have obtained his whole knowledge of this important subject from one or more of these incomplete papers written for an entirely different purpose. Yet he published a letter in the JOURNAL of the 15th inst., in which he confesses his inability to succeed with a treatment of which he must necessarily know so little. Immediately on receipt of the JOURNAL containing his criticism, I wrote him the following polite letter:

YOUNGSTOWN, OHIO, Dec. 15, 1894.

MY DEAR DR. CALDWELL:—Presuming that the object of your letter in the current issue of the JOURNAL of the AMERICAN MEDICAL ASSOCIATION is to "seek for the truth," and believing that if put in possession of all the data at your disposal, I could not only show you why you failed to secure the results which my charts show are possible, but how you may obtain even better results than I have had, because my work has been done under difficulties and I have made many mistakes which you could avoid.

Will you therefore give me the necessary information by answering the inclosed list of questions:

1. How many cases of typhoid fever have you treated by my method?
2. On what day of the disease did you begin the treatment of each case?
3. What was each patient's condition when the treatment was begun?
4. What was the exact formula used in each case?
5. What was the size of doses given?
6. How often were they given during the first six days?
7. What other medicines were given besides those advised by me?
8. What was the daily morning and evening temperature?
9. Give the pulse record.
10. How many times did the bowels move each day?
11. How soon after beginning treatment did the tympanitis disappear?

And add any further information that you may possess about them. Will you also send me samples of the remedies you used, or if this is not possible give me the name of the druggist who prepared them for you, so that he may send me sample on order?

Hoping to hear from you at once, I beg to remain, my dear sir,

Most respectfully yours,  
JOHN ELIOT WOODBRIDGE.

P. S.—Should you have other cases of typhoid fever and will telegraph me, I will go to Freeport free of cost to your patient or yourself, and show you how to shorten the course of the disease to less than two weeks and how to save the life of every patient.

This letter he probably does not consider worthy of his attention, as more than a week has elapsed and I have received no answer. His published letter is therefore the only measure I have by which to judge of his ability to treat a case of the disease which he truly designates "terrible."

First, he says I have published . . . . "in several medical journals." . . . . This is not true. I have never published a paper on typhoid fever in any journal, magazine or paper, except the JOURNAL of the AMERICAN MEDICAL ASSOCIATION. One paper was published in the Transactions of the Ohio State Medical Society.

. . . . a "paper" . . . . So he probably has seen but one of my five published papers on the subject, and he does not say which one.

He next errs by calling a paper or series of papers, written to prove that typhoid fever can be aborted. . . . "paper on the treatment of typhoid fever." Notwithstanding the fact that less than two and one-half of the sixty pages, refer to treatment. He says: "The first part of his prescription" (by which he evidently means—first prescription)—"containing" . . . . "guaiaicol." Is this only an inaccuracy, or does Dr. Caldwell not know the difference between "guaiaicol" an acrid, poisonous, oily liquid and guaiaicol carb., a white, crystalline non-poisonous salt?

It would be unreasonable to suppose that Dr. Caldwell would write with less care or less accurately for the thousands of readers of the JOURNAL than he would for his druggist. Therefore judging his prescriptions by his published criticism we are justified in giving expression to some surprise that "his vigorous young woman" was in condition to have a temperature of 105 degrees F. after "two weeks trial" without taking into consideration the fact that she was subjected to at least three different methods of treatment, viz., the Brand or bath, the Woodbridge, and the compromise or sponge treatment.

Without taking the trouble to criticize the remainder of this letter, it seems clear that if others have tried my abortive treatment of typhoid fever with no better preparation and as carelessly as the Doctor's letter would lead us to suppose he conducted his experiment, then we shall probably hear of other failures as dismal. We shall undoubtedly hear, too, of some successes, and one brilliant success should outweigh an hundred failures in estimating the value of the treatment. The failures may be due to inert or impure drugs, to carelessness or want of skill in compounding them, to their improper administration or even to the administration of other remedies interfering with their action. Thus the physician who prescribes, the nurse who administers, the druggist who dispenses, or even the pharmacist who manufactures the remedies, one or all of them may contribute to the failure, making that but at best a negative evidence, while a single well established success puts the stamp of value on the treatment. The gun that speeds the bullet true to the mark in one hand, if equally well charged and truly held, will do so in every hand, but if the powder be poor, the bullet untrue, or the hand that holds the gun unsteady, no matter how accurate the weapon may be, the bullet may be expected to fly wide of the mark.

Respectfully yours,

JOHN ELIOT WOODBRIDGE, M.D.

## Treatment of Typhoid Fever.

COLUMBIANA, OHIO, Dec. 25, 1894.

To the Editor:—In response to the physician who has been using Dr. Woodbridge's treatment for typhoid fever and has not met with the success he had hoped for and that Dr. Woodbridge had assured him he would meet with; and to all who would try it, I desire to say that I have been carefully testing it for the past three months, and so far it has proved very successful in my hands. In that time I have had an unusual number of cases of typhoid fever. Not being satisfied with the old method of treatment, I was induced to try the plan proposed by Dr. Woodbridge. Some of my cases presented unusually severe symptoms, temper-

ature ranging as high as 105.5. While I was not able to abort it entirely in all of my cases, yet the temperature was materially reduced in a very short time, the fever ran a very mild course and my patients were soon in a convalescent stage.

I find this treatment must be employed early. In one or two cases I used other measures first; finding they did not accomplish the end desired, I then adopted the Woodbridge method after a delay of a day or so. In these cases my results were not so good as when I used his measures first. Perhaps the physician who says he practices very conservatively, failed to use the measures early enough to abort the disease, and thus became discouraged with the remedy. If this gentleman, and others also, will give the method a fair trial, using the treatment early and calling Dr. Woodbridge in consultation in the severer cases, allowing him to explain more fully his plan of treatment, I think the results will be more satisfactory.

Yours fraternally,

C. R. JUSTICE, M.D.

MERCED, CAL., Dec. 27, 1894.

*To the Editor:*—Replying to Dr. Caldwell, will say I have tested the antiseptic treatment of Dr. Woodbridge sufficiently to convince me of its great value. I have been unable, so far, to carry out this treatment *exclusively* from beginning to end of case, for various reasons, but the results obtained in the way I used it, convince me of its superiority. Then it appeals to the *reason*; it not only destroys the bacilli but carries them off, and by giving large quantities of water we have an (almost) antiseptic irrigation of the intestines.

W. N. SHERMAN, M.D.

### The Practical Importance of Well Established Facts in Therapeutics.

*To the Editor:*—Dr. N. S. Davis puts the questions: If alcohol when taken into the living body directly diminishes nerve sensibility, muscular force, and so alters the constituents of the blood as to retard both the internal distribution of oxygen and natural tissue metabolism in direct proportion to the quantity to be taken (the established fact according to Dr. Davis), why do we continue to speak and write concerning it, or to use it, as a *stimulant, heart tonic or restorative agent*? The answer seems to be that experience proves that we are right in spite of the supposed established facts.

Let me briefly illustrate: In the year 1870 I started to walk from Courmayeur to Chamounix via the Col du Géant, a climb of 10,000 feet and a march of some six or seven hours over the Mer de Glace. I arrived at the summit of Col between 9 and 10 o'clock A.M., and after resting one hour for breakfast, commenced the descent. At this hour the heat was intense, and the motion of walking on the glacier was as irregular and uncertain as on board a ship. I was seized with *mal de montaigne*, vomiting, diarrhea and nervous prostration exactly similar to similar experiences at sea, and I lay down for an hour and slept, but no sooner did I begin to walk than the vomiting returned. My guides and porter made a *chaise à porteur* of their staves and alpenstocks. They essayed to carry me, but the motion of their movements was even worse than that of walking and the attempt was given up. With the prospect of being benighted on the ice I then sent on two men to Montainvert with instructions to return as quickly as possible with wraps, fuel, restoratives and other requirements for passing the night in safety. In the meantime I struggled on for a few yards at a time, until at last even a few steps brought on such prostration that I was compelled to stop. My condition became alarming, my face was deathly, I was pulseless, my hands and feet cold and I was quite unable to rise; and my friends covered me up in shawls, chafed my hands and did their best to

maintain my circulation. We were waiting most anxiously for the return of my men with the necessary restoratives, when we were accosted by an Irish gentleman on his way to spend the night upon the glacier with the object of climbing one of the neighboring peaks to see the sun rise. He saw and diagnosed my case. He took out his flask of brandy and in the course of fifteen minutes gave me fully half a pint without a drop of water. Within another ten minutes I got up and shook myself and declared my ability to walk. I boasted of having on a pair of brandy boots. I walked forward without a trace of nausea, crossed the "Mauvais pass" without assistance or mistake, and arrived at the Hotel Montainvert after three hours hard walking, and after a long sleep awoke to eat the heartiest breakfast of my life. It is safe to say that the sensibility of my nerves was not reduced, that the distribution of oxygen was not retarded, that the natural tissue metabolism was not interfered with. On the contrary, my nerves were stimulated, my heart action was excited and my whole body and muscular system was raised to a condition wonderfully like health.

Let me give one more personal experience: Just eleven years ago I had been greatly overworked and had lost much sleep. I was in close attendance upon a patient who died from pneumonia of a most malignant type. I paid him a long visit a few hours before his death and although boasting to a friend of my perfect health I remarked on getting into bed that I felt a curious sensation in my right loin as though I had suffered from a blow. I slept well but next morning the pain returned. Then cough, hemoptysis, rapid pulse. Temperature 104 degrees and in twenty-four hours all the symptoms of double pneumonia were manifest. At the age of 62, with an intermittent pulse the prospect was not flattering. On consultation, alcohol was the remedy prescribed. I took half an ounce of brandy or whisky every two hours. The pulse became regular and the symptoms slowly declined. I took the dose religiously for nine days and my recovery was perfect. I am to-day in my seventy-fourth year. Only a few weeks ago I climbed 3,200 feet in three hours and a quarter, without the least distress, and the day afterward walked for at least seven hours. I do not remember the time when I have not been accustomed to drink wine with my meals. For over fifty years I have drunk wine every day, and I may say truly in the last forty years I have not willingly drank forty glasses of cold water to allay my thirst. After such personal experiences, (and indeed I can relate even more startling results in the case of patients) I may surely be pardoned in doubting the apparent facts which Dr. Davis regards as well established.

Yours very obediently,

J. H. STALLARD, M.B. Lond., M.R.C.P., M.R.C.S.,  
and late Physician to the San Francisco Polyclinic.

### PUBLIC HEALTH.

**Low Death Rate.**—Computed on the figures of the school census of April, 1894—which fixed the population at 1,567,727, or 32,273 less than the population of 1893—the death rate of Chicago last year was 15.1 per 1,000. The Health Commissioner, Dr. Reynolds, reports 23,701 deaths from all causes, as against 27,083 during the previous year.

**Glanders in Havana.**—*El Progreso Medico* states that, while glanders has been known to exist in Havana for years, the unusual number of cases in 1894 ought to attract the attention of the health authorities. The remedy is well known to science, but the authorities either don't know it or won't apply it. It is not grooms alone who contract the disease;

no one is safe from it, and it is often the passer-by who is attacked. *El Progreso* quotes a distinguished veterinary surgeon as saying recently that 10 per cent. of the 15,000 horses in Havana are affected with the disease. It is not surprising, then, that glanders numbers more cases than any other infectious disease in that city. To the cases in private practice must be added those in the Mercedes Hospital; in one ward alone clinical and bacteriologic examinations showed the presence of five cases of the disease from January to August. Dr. Salagridas, who has charge of the ward, says glanders is favorably influenced by both yellow fever and typhoid fever; he has seen three years of the first and two of the latter. The journal cited urges that stables be thoroughly inspected and all diseased animals removed; and points out that in Germany and elsewhere the government, in the interest of public health, pays for horses destroyed, so that owners have no incentive to hide diseased animals; and adds that in really civilized countries human life is held at its true value, but in the present case, while the indifference is general, the fault is in great part due to the authorities. The professional press has sounded the alarm many times, but the danger is as serious and as menacing as ever.

**Specific Organisms of Vaccinia and Variola.**—The etiology of smallpox is a problem of such interest that any contribution to its study of *prima facie* merit should be brought promptly to the attention of the bacteriologic world. During the past year Mr. J. Christian Bay, bacteriologist of the Iowa State Board of Health, has carried on a series of investigations concerning the specific organisms of vaccinia and variola, a detailed account of which has been forwarded to the *Medical News*. Through the courtesy of the author the JOURNAL is enabled to present a summary of the important points of his paper. During the past thirty years many bacteriologists—among whom the author cites Chauveau, Hallier, Luginbuehl, Beale, Cohn, Weigert, Klein, Klebs, L. Voigt, Pfeiffer, Hlava, Koch, Feiler, Crookshank, Copeman, Rille, Martin, Coze, Feltz, Baudoin, Plaut, Zimmermann, Toussaint, Buttersack, Landmann and Dräer—have investigated the smallpox and vaccine lymph, and some of them have found one or more cocci to which they ascribed the rôle of *causa morbi*; others were of the opinion that animal parasites caused the disease; and a few—e.g., Plaut and Zimmermann for sheep-pox—have isolated bacilli of different species, common saprophytic bacteria, none of which seemed to have any causal relation to vaccinia or variola. Plate cultures after Koch's method reveal no organisms in vaccine or smallpox lymph, neither do microscopic examinations. The author prepared test-tube cultures in Pasteur's fluid and in bouillon rendered alkaline with  $\text{Cl Na}$ ; vaccine points were dropped, or samples of smallpox deposited, in the medium under the usual precautionary measures. On the first day after incubation the medium became slightly turbid and, during the second and third days, a grayish, folded, greasy-looking film developed on the surface. Microscopic examination showed the presence of bacilli, measuring  $0.6$  to  $1\mu$  by  $0.2$  to  $0.3\mu$ ; they are colorless, motionless and bear one spore at each end of the cell—hence the organism has been referred to Kern's genus *Dispora* and named *Dispora variolæ*. It was found, with three exceptions, in sixty-five cultures from vaccine points and in forty cultures from the lymph of confluent smallpox; two cultures failed to respond to inoculation. The organism is somewhat polymorphous; in old cultures the cells are arranged to a great extent in threads; the dimensions of the cells also vary as above stated. Spores are found being formed at the beginning of the cell development and the number of spores constantly increases as development progresses; in old cultures very few vegetative cells are found while the number of free spores largely predominates. The author is of the opinion that the organisms, cocci, described by others as *Micrococcus vaccinæ*, *M. variolæ*, *Microsphaeria vaccinæ*, etc., are identical with the spore stage of his *D. variolæ*; and believes that his observations and conclusions as to the facts of the spread of smallpox warrant

the assumption that the spores are the main source through which the disease, itself, as well as vaccinia, is reproduced. Mr. Bay is further investigating the results of inoculations upon animals and experimenting with a view to the preparation of vaccine in the laboratory. It is in this last object that health officers and sanitarians will be most directly interested and hope that Mr. Bay's claims may be substantiated by other investigators.

**Summary of Smallpox in 1894.**—From reports of JOURNAL correspondents and other sources the following summary of the diffusion of smallpox in the United States in 1894 has been compiled:

Arizona: Nogales, 1 case.  
 Connecticut: Manchester, Winchester, Canaan, Norfolk, South Norwalk, Waterbury, New Haven, Putnam, Bridgeport; nine places, 52 cases, 11 deaths.  
 District of Columbia: Washington; 18 cases, 7 deaths—one new case and two deaths, December 31.  
 Georgia: Atlanta, Senoia; two places, 12 cases.  
 Illinois: Alton, Aurora, Bloomington, Braidwood, Chicago, Danville, Decatur, Downer's Grove, Drainage Canal, East St. Louis Race Track, Edwardsville, Elgin, Evanston, Freeport, Galesburg, Genoa, Greenbush, Harvey, Havana, Hoopston, Joliet, Jonesboro, Kingston, Libertyville, Lombard, Maywood, Morris, Paris, Peoria, Rockford, Rock Island, Roodhouse, Round Grove, Spencer, Sandwich, Toluca, Tolono, Upper Alton; thirty-nine places, 3,209 cases, 1,050 deaths; in Chicago, 3,062 cases, 1,029 deaths; in the State *ex Chicago*, thirty-eight places, 147 cases, 21 deaths.  
 Indiana: Fort Wayne, Kewanna, South Bend, Crown Point, Indianapolis, Fulton County, Marshall County, Pulaski County, Wayne County, Johnson County, Blackford County, Lake County, DeKalb County, Kosciusko County, Whitley County, Grant County, Walkerton; seventeen places and counties; 105 cases, 17 deaths.  
 Iowa: Tama and six other places.  
 Kansas: Atchison; 44 cases, 9 deaths.  
 Kentucky: Louisville, Paducah; two places, 20 cases.  
 Louisiana: New Orleans; 5 cases, 1 death.  
 Maine: Kennebec, Bangor; two places, 3 cases, 1 death.  
 Maryland: Baltimore, Glymount; two places, 9 cases.  
 Massachusetts: Boston, Chelsea, Springfield, Worcester, Lawrence, Yarmouth, South Boston, Lynn, Waltham; nine places—182 cases, 30 deaths in Boston.  
 Michigan: Otsego, Crystal Lake, Otsego Tp., Menominee, Ishpeming, Kalamazoo, Jackson, Marquette, Bay City, Muskegon, Grand Rapids, Sturgis, Napoleon, Summit, Detroit, Allegan, St. Joseph, Flint, Frenchtown Tp., Farmington Tp., Ridgeway Tp., Berlin Tp., Ypsilanti, Pontiac, Macomb Tp., Clayton Tp., Manchester, Rivers Tp., Norvill, Cheboygan, Royal Oak, St. Johns, Sewaba Tp., Adrian Tp., Danby Tp., Watersmeet Tp.; thirty-six places, 180 cases, 41 deaths.  
 Minnesota: St. Paul, Duluth, Two Harbors, Red Clover Tp., La Crescent Tp., Belle Plaine, Brainerd; seven places, 29 cases, 3 deaths.  
 Missouri: St. Louis, Mountain Grove; two places, 21 cases, 2 deaths.  
 New Jersey: Hoboken, Jersey City, Newark, Paterson; four places.  
 New York: New York city, Brooklyn, Red Hook, Tivoli, College Point, Walworth, Manchester, Ontario, Yonkers, Utica, Sing Sing, Palmyra, Rochester (near), Geneva, Ithaca, Mt. Vernon, Stapleton, Salina, Newburg, Port Jervis, Nelsonville, Binghamton, Wayne County, Syracuse, Schenectady, U. S. revenue cutter *Manhattan*, five ocean steamers at quarantine—one on December 31; twenty-six places, 1,690 cases, 442 deaths.  
 Ohio: Springfield, Columbus, Lima, Dayton, Worthington, Toledo, Cleveland, Deerfield, Cincinnati; nine places.  
 Pennsylvania: Oakdale, Jeannette, Maconaquia, Reading, Fritztown, West Leesport, Gibraltar, Friedensburg, Mechanicsburg, Carlisle, Wilton Grove, Pittsburg, Williamsburg, Tyrone Forges, Elk Co., Williamsport, Philadelphia, Shamokin, Dagus Mines, Riverside, Danville, Lee, Shickshinny, Muncy, Lewistown, Jerseytown, Harrisburg, Lewisburg, Blandon, Walnuttown, Liedel's, Hyde Park, West Hempfield, Derry Tp., Dorrancetown, Burt, Carroll Tp., Shermansdale, McKeesport, Towanda, Ridley Park; forty-one places, 1,066 cases. December 18 there were 40 cases and 100 houses in quarantine in Philadelphia.  
 Rhode Island: Providence; 5 cases, 1 death.  
 Tennessee: Memphis, Nashville, Chattanooga, five villages near Nashville; eight places, 25 cases.

Texas: Victoria, San Antonio, Texarkana, El Paso, Cleburne; five places, 106 cases, 16 deaths.

Vermont: Brattleboro, Pomfret, Washington; three places.

Virginia: Southwest Virginia, Lunenburg, Shendon; three places, 48 cases.

West Virginia: Lewisburg; 12 cases.

Wisconsin: Janesville, Milwaukee, Juneau, Sheboygan, Portage, Jefferson, Elkhorn, DePere, Camp Lake, Beloit, Lewisburg, Neenah, Fort Howard, Madison, West Superior, Green Bay, Manitowoc, Dodge County, Waukesha, Merrimack, Menasha, Wausau, Juda, Granville, Greenfield, Wauwatosa, Raymond, Lake, Dover, LaCrosse, Two Rivers, Liberty, Oneida Reservation, Milwaukee Tp., Ellsworth, Wonewoc, Franklin, South Milwaukee, Muskego, Spring Prairie, Beaver Dam, Rochester, Rhinelander; forty-three places, 1,866 cases, 399 deaths—in Milwaukee, 1,161 cases, 317 deaths; in the State *ex* Milwaukee, 705 cases, 82 deaths; and at the end of the year Two Rivers and Rhinelander were the only infected places outside of Milwaukee.

The foregoing, though by no means complete, shows the wide extent of territory invaded—twenty-five States, one Territory and the District of Columbia, a total of 282 infected localities, with an aggregate of 8,719 cases and 2,084 deaths reported. In five States from which the reports are most complete, viz., Connecticut, Illinois, Michigan, Minnesota, and Wisconsin, there were 132 infected localities, with a total of 1,113 cases, exclusive of Chicago and Milwaukee. An examination of the individual reports leads to the belief that there were fully 10,000 cases of the disease with an aggregate of 3,000 deaths during the year. Twelve infected ocean steamers were detained at the quarantines at Boston, Darien, Ga., Delaware Breakwater, Mobile, and New York—the last being a Thingvalla liner at the port of New York, December 31.

## BOOK NOTICES.

**Atlas of Clinical Medicine.** By BYRON BRANWELL, M. D., Assistant Physician to the Edinburgh Royal Infirmary, etc. Vol. iii, Part I. Edinburgh: Printed by T. and A. Constable at the University Press. 1894.

Part I of Vol. II of this excellent work has appeared. The high standard is maintained as in the past. The contents are: 1, The Thyroid Treatment of Skin Diseases; 2, Poliomyelitis Anterior Acuta; 3, A Remarkable Case of Cancer of the Breasts, Spleen and other Organs.

There are several well executed plates accompanying, showing psoriasis, lupus and ichthyosis treated by thyroid extract; also, two plates showing drawings in cases of poliomyelitis.

**Transactions of the State Medical Society of Wisconsin.** For the year 1894. Madison, Wis. Cl., pp. 504.

This volume is handsomely printed and contains all the papers read at the last meeting of this flourishing society held at Milwaukee, under the Presidency of Dr. B. C. Brett of Green Bay.

It is well edited by Secretary Sheldon and the society is to be congratulated on the excellence of the papers and the typographical appearance of the volume. Dr. Reineking, Chairman of the Committee on Surgery, began his annual report with an appreciative sketch of the lamented Billroth. The next annual meeting will be held at West Superior, Wis., June, 1895. Almon Clarke, M.D., of Sheboygan, is President and C. S. Sheldon, of Madison, Secretary.

**The Medical Register of New York, New Jersey and Connecticut for 1894-5.** Published under the supervision of the New York Medico-Historical Society. JOHN SHRADY, M.D., Editor. Volume xxxii. G. P. Putnam's Sons. 1894.

This ever-welcome Annual contains the usual guide-lists and information, as to current medical history, for the three States named. The book resembles closely its recent predecessors, being bound in green cloth, as comports with the nickname or quick name that it has held for more than a quarter of a century. The type is newer and the paper cleaner-looking than some former issues, but the general

make-up follows the traditions of the book. The only illustration proper to the work itself is a photogravure of the late editor, from 1878 to 1893, Dr. William T. White. The likeness will be readily recognized by members of the Association as belonging to a frequent though quiet fellow member. The information regarding the hospitals and other institutions in and around New York is arranged for local reference chiefly, but it can be made available to others at a distance who have need for consultation or post-graduate training at the metropolis.

Every library of considerable size throughout the country would do well to have a copy of this book for the reference table. This book stands for the best interests and influences of the region whence it issues, and its supporters are the filial sons of the National Association. Dr. John Shradý, the new editor, is not altogether new to the work, since he was one of the earliest of the compilers, when the book was much less of an institution than it is now. He has been identified with the work of the Medico-Historical Society, and with medico-historical research in New York during his whole professional life. He has many qualifications for the editorial charge of this valuable annual. The delayed issue of the volume this year should be remedied, if possible, in 1895; the profession is ready to welcome any annual directory if it appears on or before June 15; if the date is later than that, its members begin to grow more and more querulous; and some become indifferent.

**Diphtheria: Observations on its History and Progress, more especially in New Orleans.** By JOSEPH JONES, M.D., LL.D., New Orleans. Pp. 28, paper. 1895.

In this brochure Professor Jones makes some valuable suggestions on the causation of diphtheria, its pathology, treatment and prevention. He concludes as follows:

After careful examination of all the available facts relative to the origin, treatment and prevention of diphtheria, I have come to the conclusion:

1. That the United States Government is the proper authority to whom the people should look for the institution of the proper measures for the eradication, treatment and prevention of diphtheria, and similar infectious and contagious diseases.

2. The Congress of the United States should pass the necessary acts empowering the President to appoint three Commissions, composed as follows:

(a).—A Commission selected from the surgeons and assistant surgeons of the Regular Army, empowered to make the necessary investigations, furnished with the necessary means to establish the necessary bacteriologic laboratories in the large cities, for the manufacture and continuous supply to the citizens of the United States of the antitoxin serum for the treatment of diphtheria, yellow fever and similar diseases.

(b).—A Commission selected from the surgeons and assistant surgeons of the medical officers of the United States Navy, empowered to institute the necessary investigations, furnished with the necessary means to establish the necessary bacteriologic laboratories in the large cities, for the manufacture and continuous supply of the antitoxin serum for the treatment of diphtheria, yellow fever and similar diseases.

(c).—A Commission selected from the surgeons and assistant surgeons from the United States Marine-Hospital service, empowered to institute the necessary investigations, furnished with the necessary means to establish the necessary bacteriologic laboratories in the large cities, for the manufacture and continuous supply of the antitoxin serum for the treatment of diphtheria, yellow fever and similar diseases.

These Commissions, after thorough organization, should act in entire accord with each other, and with the State Boards of Health, or with similar commissions appointed by the Governors of the individual States.

It is evident that the United States possesses unlimited supplies of horses in its cavalry and transportation service; and it is farther evident that with such an arrangement there need never be a scarcity of the antitoxin supply for the treatment of diphtheria, yellow fever and similar diseases.

## NECROLOGY.

W. J. HALL, M.D., an American physician, residing in Corea, during the past three years, is reported by a cablegram, dated December 4, to have died from an attack of typhus fever. The last intelligence by mail from him had reference to his helpful visits, as a volunteer surgeon to one of the battlefields in Corea. Dr. Hall was a graduate in medicine at the Bellevue Hospital Medical School, and was an East Side missionary for two or more years, to fit him the better for work among the poorer Orientals. He was only 35 years of age at the time of his last illness, which must have been rapidly fatal.—Thomas P. Norris, M.D., formerly a coroner of Brooklyn, N. Y., died from renal disease on Dec. 21, 1894. He was a graduate of the Medical Department of New York University in 1854, and had been in Brooklyn for the greater part of forty years. He was for a time, however, a practitioner in East Tennessee. He was a native of Ireland, but came to this country when he was about 10 years old. He was a good political speaker, and his services were sought often and occasionally rewarded. He held an important appointive office, that of Commissioner of Charities. His final illness was somewhat protracted.—Sylvester Mead, M.D., of Greenwich, Conn., died December 11, aged 88 years. He was believed to have been the eldest living alumnus of the Yale Medical Institute, he having graduated therefrom in the year 1829. Dr. Mead died in the harness, having continued in the practice of his profession sixty-five years.—Thomas H. Parkes, M.D., of Brooklyn, N. Y., died on December 21. He was an American by birth, of English parentage, and was 31 years of age. He died suddenly from edema of the glottis. Two hours before his death he was present in good health at a social gathering. He was a graduate in the year 1890 at the Long Island College Hospital.—R. H. Cummins, M.D., of Wheeling, W. Va., died December 13, of diphtheria, contracted while in attendance upon several severe cases of that disease. He was a graduate of the University of Pennsylvania and a man of fine character. He met death fearlessly, a martyr to his chosen calling.—George Jewett, M.D., of Fitchburg, Mass., December 16, aged 68.—Joseph W. Taylor, M.D., of Long Branch, N. J., December 18, aged 36.—J. M. Cook, M.D., of Muskegon, Mich., December 21.—Ward Cook, M.D., of Pendleton, Ind., December 24, aged 87. He had practiced medicine for fifty-seven years and was a member of both the county and State medical societies.—J. M. Hopper, M.D., of Rutherford, N. J., December 18, aged 70.—J. M. McMeen, M.D., of Danville, Ill., December 28, aged 65 years.—Dr. Lezenber, at Logansport, Ind., December 24.—F. H. Wilson, M.D., Leavenworth, Kan., December 25, aged 66.—Henry M. Hooper, M.D., Rutherford, N. J., December 21.

## SOCIETY NEWS.

**The Muskingum County (Ohio) Medical Society** held a meeting in Zanesville, December 16.

**The Frontier Medical Association** held its semi-annual meeting at Huntington, Que., December 19.

**The Central Wisconsin Medical Society** held a meeting in Janesville December 27.

**The Northern Tri-State Medical Association** met at Hillsdale, Mich., December 20. Attendance one hundred.

**The Binghamton (N.Y.) Academy of Medicine** held a meeting December 18. The program was interesting and the attendance large.

**The Academy of Medicine and Surgery** of Richmond, Va., held a meeting December 16. The following officers were elected for the ensuing year: President, W. S. Gordon; First Vice-President, V.W. Harrison; Second Vice-President, R. D. Garcin; Third Vice-President, A. L. Wellford; Secretary and Reporter, Mark W. Peyser; Assistant Secretary, W. S. Beazley; Treasurer, J. T. Woodward, and Librarian, J. F. Crane.

**Northwestern Ohio Medical Association.**—The forty-ninth semi-annual meeting of the Northwestern Ohio Medical Association closed its session at Lima, Ohio, December 19. The following officers were elected: President, J. K. Woods, Lima; Vice-President, Joseph Sager, Celina; Second Vice-President, W. E. Hoover, Lima; Secretary, Chas. Graefer, Sandusky. The next meeting will be held in Findlay June, 1895.

**The Kansas City Medical and Surgical Society** held its annual election of officers December 22. The following were elected: F. G. Henry, President; J. W. Foster, First Vice-President; Z. Nason, Second Vice-President; Theodore W. Schafer, Third Vice-President; C. M. Stemen, Secretary; Edward Schaefer, Assistant Secretary; P. C. Palmer, Treasurer.

## MISCELLANY.

**Association of Erie Railway Surgeons** will hold their annual meeting January 10 at Youngstown, Ohio; Dr. C. B. Kibler, President.

**College of Physicians and Surgeons.**—[By telegraph to this JOURNAL.] The annual election of the College of Physicians and Surgeons of Philadelphia was held Jan. 2, 1895. Prof. J. M. Da Costa was elected President, and Prof. John Ashurst Vice-President, for the ensuing year.

**Honors for Pasteur.**—At a recent meeting of the Municipal Council of Paris, the Superior Normal School was given 1,500 francs for the purchase of a bust of Pasteur and the Council decided that the Rue d'Ulm should be named Rue de Pasteur.

**Souchon's Anesthetizer.**—Dr. Souchon applied for a patent for his anesthetizer to test the originality of his invention. Having succeeded, he now waives all his rights and privileges in all cases where the patent is used for medical purposes only.

**Centenary of Vaccination.**—The German Institute for Vaccination is preparing to celebrate, in 1896, the centenary of Jenner's discovery. It is proposed to have at the same time an exposition of all articles concerning vaccination—old and new instruments and methods of preserving vaccine, original manuscripts on variola and vaccinia, medals, portraits and autographs of celebrated inoculators, vaccinators and anti-vaccinators.

**Action of High Pressures on Bacteria.**—Roger has studied the action exerted on bacteria by compression of the liquids containing them. The pressure varied from 1,000 to 3,000 kilos per cubic centimeter. The staphylococcus aureus and the bacillus coli were not affected, the former retaining its chromogenic powers. At 3,000 kilos the streptococcus had its vegetability and virulence affected. The anthrax with spores after supporting a pressure of 3,000 kilos grew about as well as before, but its virulence was slightly diminished. The anthrax without spores, on the contrary, was strongly attacked both as to vegetability and virulence; the cultures which had supported 3,000 kilos did not die for eighteen or nineteen days. The author thinks—*Le Progres Medical*—that we may thus be able to create a chronic disease analo-

gous to that which Phisalix obtained by inoculation with vaccine from animals with anthrax.

**A New Instrument.**—Maclean's general utility knife may be carried in the pocket like a common penknife and may be useful for *any surgical procedure* from tracheotomy or tonsillotomy to laparotomy or amputation at the hip joint. It is so

constructed as to be very easily rendered aseptic, and inclosed in a chamois skin envelope, it can be carried in the pocket with absolute safety. Suggested and recommended by Donald Maclean, M.D.

**An Entomologic Patient.**—The editor of the *Brooklyn Medical Journal* gives the following as an incident, founded on fact: "A few weeks ago an eccentric appearing individual entered the office of one of our most distinguished surgeons, who lives on the corner of two well-frequented streets, and said that he had come from the east end of Long Island to consult a physician whose address he was unable to find. When asked the name of the physician he responded that he could not at the moment recall that either. Then, pausing for awhile, he turned to the doctor and said: 'Well, how are you on worms on this corner, anyway?'"

**The Railway Surgeon.**—Acceptance and resignation of Dr. Reed. The following is a copy of a letter which is self-explanatory, and consequently needs no comments:

COLUMBUS, OHIO, Dec. 19, 1894.

DR. S. S. THORNE, President National Association Railway Surgeons, Toledo, Ohio.

Dear Doctor:—Having been officially notified of my unanimous election to the position of Editor of the American Academy of Railway Surgeons, and having decided to accept the same, I beg leave to tender my resignation as the duly elected editor of *The Railway Surgeon*, the official organ of the National Association of Railway Surgeons, to take effect Jan. 1, 1895.

With my best wishes for a continuance of the prosperity of the National Association of Railway Surgeons, and the future success of *The Railway Surgeon*, its official organ, I have, my dear Doctor, the honor to remain,

Very respectfully yours, R. HARVEY REED, Editor.

**Foot and Mouth Disease in Germany.**<sup>1</sup>—The flap and foot-rot (*Maul- und Klauenseuche*) has again broken out among the farm animals in central Germany, notably the Voigtland and Saxe-Altenburg. This is more unfortunate for the farmers in this part of the country, as only two years ago the same disease reduced the stock considerably, and as the drouth of 1893, with its subsequent fodder scarcity, compelled the farmers to slaughter large numbers of their cattle. Though the local authorities are doing their utmost to prevent an extension of the disease, they have, as it appears, not yet succeeded, for nearly every new issue of the official papers mentions new cases. The frequent appearance of the disease in the same locality is, certainly, no evidence of a healthy condition of farm animals.

ANNABERG, Oct. 16, 1894.

THEO. M. STEPHAN, Consul.

<sup>1</sup>The Secretary of Agriculture in acknowledging the receipt, by reference from the Department of State, of a copy of Consul Stephan's report, says: "Consul Stephan states that 'the flap and foot rot has again broken out among the farm animals in central Germany.' As no such disease is known in English-speaking countries, it is fortunate that the Consul placed the German designation (*Maul- und Klauenseuche*) in parenthesis, for otherwise it would have been impossible to determine whether this was some new plague requiring unusual precautionary measures to guard against its introduction, or whether it was a peculiar name given to a well-known disease. The English equivalent of *Maul- und Klauenseuche* is foot-and-mouth disease. This is an extremely contagious and rapidly spreading disease, which does not exist on the American continent, and requires the most rigid measures for its exclusion."—*U. S. Consular Reports*, December, 1894.

**The Williams Hospital at Pang-Chuang, China.**—This hospital has been so named in honor of the late Hon. S. Wells Williams, M.D., who remembered it in his will. The sum of \$3,000 here judiciously spent has given the place a walled in plot of ground with buildings and gatehouse. In very busy times there have been 100 male patients and 60 female. The cost of the plant is a little more than one-half what the endowment of a single bed in one of our city hospitals would require. For the sake of argument the capacity of this hospital being placed at 100, the cost of the plant, per bed, may be placed at \$30, whereas not a few of ours are rated at fifty to one hundred and fifty times that amount. Dr. Albert Peck, now in charge, states that strangers seek his place from widely scattered and very distant places. Some of them have to travel 200 miles by very tedious means of transportation. Since the spring of 1880 not less than 65,000 persons have visited the hospital or dispensary. The following is an "instructive case" of surgery attended by Dr. Peck: "Years ago, while living at Pao-ting-fu, a little man made his appearance at the hospital with a large tumor on his neck. He had never seen a European before, but came with his mind fully made up for an operation, owing to reports he had heard of us in his country home from patients who had been at the hospital. Against the remonstrances of his friends and neighbors, he had sold his little property in order to get money to live on. His simple reply to these remonstrances was that his life was made a burden to him by his tumor, and he was going to try the foreign doctor and, in the expressive idiom of his language, if he was 'cured well' he could earn some more money, and if he was 'cured dead' he wouldn't need it. The foreign doctor tried to persuade him against so formidable and risky an operation, but without avail. Fortunately, he lived through it, and the healing of the wound went on normally until delayed by a rather severe attack of erysipelas. Before this danger was passed he sent word by the gatekeeper that he must go home, as his money was spent. The patient was told that he would not be allowed to leave yet. But the next morning he was missing. It was supposed that the man had died, but a long time afterward it was learned that he was alive and acting as a self-constituted preacher of the little of Christian doctrine that he had been able to learn while under treatment. While in the hospital he had seemed very stupid; no one thought he had taken in much of the truth; but he had bought and paid for a little elementary book and learned to read it. The simple explanation had remained in his memory, and after his recovery at home he had taken his book with him when visiting the little fairs where all the business of neighboring villages is done; he had been notable as the man with the large tumor, and now when he came around without it he was naturally an object of curiosity. They said he kept a kerchief around his neck, and when the crowd gathered around he would say: 'My friends, when I was in the hospital they taught me of a religion there that is far more precious than the cure of my body. I have a little book here which tells about it, and if you will sit down and let me read and explain it to you, then I'll show you my neck.' His cup was small, but it was just as full as though it were an ocean brimming over."

#### Louisville Notes.

**HEALTH OFFICER'S REPORT.**—During the past week there were sixty-two deaths, the largest number, sixteen, being due to pneumonia; and there were ten deaths from phthisis.

**MEDICAL TESTIMONY.**—The President of the United States recently pardoned a prisoner undergoing sentence in the Jeffersonville Prison. The pardon was granted on a certificate from several medical men that he was incurably diseased. After release he boasted of his good health, whereupon an investigation was ordered and the prisoner was afterward examined by a representative of each medical college in the city, and the first report of the prison physician was corroborated. It was found that he had a cavity in one lung, had hectic pulmonary hemorrhages, night sweats, loss of flesh, elevated temperature and considerable cough.

**NEWSPAPER MEDICINE.**—As another evidence of the oftentimes ludicrous mistakes made by newspapers in the recording of things medical, anent the case of Zink; the following appeared in large headlines over the report of the physicians' examinations: "Henry Zink will die now sure; the doctors all agree he is in a bad way. Examined by professors of all the medical colleges at the request of Dr. Peyton; he has *palpitation*, moist râles, and *breathes cavernously*." The above lines were culled from the medical report, and the report is made to read: "Physical examination left lung—*palpitation*—increased vocal fremitus, etc., and palpitation is recorded as one of the ex-convict's troubles.

**KENTUCKY SCHOOL OF MEDICINE.**—The formal opening and dedicatory exercises of this school were held December 23 at the new hospital adjoining the old building. The profession of Louisville was invited and many ladies were present. Dr. W. H. Wathen presided, Dr. J. R. Marvin gave a history of its erection. He stated that the building is owned in its entirety by the Faculty; that not a cent of money was asked from outside. He congratulated the coming classes of the school because of the advantages offered by the school now being equipped with a hospital in connection with it, and because of the perfect clinical arrangements in the dispensary. Dr. J. H. Broadus, President of the Board of Trustees in a brief speech dedicated the "Kentucky School of Medicine to the cause of science and for the relief of the sick poor." The guests at the conclusion of the remarks were invited to inspect the building and a collation was served.

#### St. Louis Notes.

**NEW ELECTRIC AMBULANCE.**—The new electric ambulance is out of the shops, and was given a trial with members of the Board of Health as passengers. It went into regular service January 1. This is designed to take the place of the ambulance car which was put in operation last summer on the Union Depot Line. It runs by the Female and City Hospitals, and has been used largely in affording transportation to convalescing patients leaving those institutions, as well as taking patients not disabled to those institutions. It is an ordinary car reserved for this special use, and runs on a regular schedule from Tower Grove Park to the switch at Twelfth and Pine Streets. The new electric ambulance was made and fitted up specially for the purpose, and has every ambulance equipment necessary. It is the intention to run switches into the grounds at the City and Female Hospitals, and also to construct an extension from the present terminus of the Tower Grove Division on Arsenal Street to the Poorhouse and Insane Asylum. It is probable that Dr. A. W. Latimer, who has been in charge of the former ambulance car, will remain in charge of the new service.—*Republic*.

**DIPHThERIA CULTURE TUBES.**—Health Commissioner Homan is in receipt of the printed instructions to physicians for the use of culture tubes in diagnosing diphtheria. These tubes are for use only in making a correct diagnosis of doubtful cases. It frequently happens that diphtheria is mistaken for croup or laryngitis, especially in the early stages, and the household and neighborhood not being apprised of the contagious nature of the disease, proper steps are not taken to isolate the patient. Thus the danger of contagion is greatly increased. The directions to physicians follow: "The patient should be placed in a good light, and, if a child, properly held. In cases where it is possible to get a good view of the throat, depress the tongue and rub the cotton swab gently, but freely, against any visible exudate or patch. In other cases, including those in which the exudate is confined to the larynx, pass the swab far back, avoiding the tongue, and rub it freely against the mucous membrane of pharynx and tonsils. Without laying the swab down, withdraw the cotton plug from the culture tube, insert the swab, and rub that portion of it which has touched the exudate gently, but thoroughly, back and forth all over the surface of the blood serum. Do not push the swab into the serum, nor break the surface in any way.

Then replace the swab in its own tube, plug both tubes, put them in the box, and return the culture outfit at once to the station from which it was obtained. The tubes will be received and report furnished by the department within twelve hours, by mail or telephone, giving the results of the bacteriologic examination without charge."—*Republic*.

#### Washington Notes.

**MEDICAL SOCIETY OF THE DISTRICT.**—At the regular meeting of the Society, held December 19, the President, Dr. S. C. Busey, delivered his annual address. He took for his subject, "The Medical Society of the District of Columbia in 1894," and made some important recommendations concerning its future.

**HEALTH OF THE DISTRICT.**—The report of the Health Officer for the week ended December 22 is as follows: Number of deaths (still-births not included): White, 54; colored, 35; total 89. Death rate per 1,000 per annum, white, 14.04; colored 19.05; total, 15.68. Death rate per 1,000 per annum for corresponding week last year 20.07.

**CENTRAL DISPENSARY AND EMERGENCY HOSPITAL.**—The end of the year will be the occasion of a change at the Emergency Hospital, in which Dr. Leonard Bell, the present resident physician, will retire to take up private practice in his home in Indianapolis. Dr. James R. Church, who is first assistant surgeon, will be promoted to fill the vacancy, and Dr. Peter Smith will become first assistant. A competitive examination was held on the 28th inst., for the position of second assistant physician. The Georgetown, Columbian and Pennsylvania Universities were represented. All the applicants received very high marks and were very evenly matched, but Dr. E. G. Shortledge, of Wilmington, Del., representing the University of Pennsylvania, made the best rating, and was recommended by the examining committee for appointment.

**WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.**—The two hundred and nineteenth meeting of the Society was held on the 21st inst. Dr. G. B. Harrison read a paper, "The Report of a Case of Puerperal Eclampsia," a very interesting discussion followed, opened by Dr. A. F. A. King. Dr. H. L. E. Johnson presented a specimen of urine from a case of chronic interstitial nephritis. The urine contained over one-third albumen by volume, which was not coagulated by heat (boiling), addition of small quantity of nitric acid and subsequent standing until cool. A large excess of acid with heat showed the presence of the amount of albumen stated. A small quantity of acid added to cold urine showed a decided cloud, but as the acid passed to the bottom of the tube all opacity disappeared. He had seen only two cases of this condition, one in a puerperal eclampsia case in which albumen was supposed to be absent. This was a specimen of acid albumen or syntonin, and is not frequently observed. He warned against carelessness in urine analysis, especially on the part of examiners for life insurance.

**SMALLPOX HOSPITAL RE-OPENED.**—The reappearance of smallpox required the opening of the smallpox hospital and as Dr. Nevit was on his wedding trip, Dr. Llewellyn Elliot was placed in charge and has displayed great skill and judgment in its management and the care of patients. The outbreak occurred in a case of confinement December 1 of still birth, with death of mother on eighth day from what was called by her medical attendant, a colored clerk in one of the Departments, puerperal fever. The undertaker noticed the eruption and regarded the case one of smallpox, but relying on the death certificate, thought his fears were groundless and the child was buried in a cemetery here, but the mother after being viewed by her friends here, was carried on a passenger steamer about seventy miles down the river in Maryland, where a public funeral was held in a church. Several cases are reported there as a result with thirteen cases here. The case originated in one of the most thickly populated courts in the district and though the Health Officer has taken every precaution, a great many new cases are expected.

**"SUNDOWN DOCTORS" CHECKED BY COMMISSIONER LOCHREN.**—The Commissioner of Pensions has issued an order that will prevent clerks in the Bureau, who are physicians, from practicing medicine after office hours. In this branch of the government service, as well as in others, there are a number of graduated physicians who attend patients after office hours, and are known as "sundown doctors."

The order states that if any clerk or employe of the Pension Bureau shall attend patients as a physician or medical adviser, it will be regarded as sufficient ground for recommending that his further services in the Bureau will be no longer required. The danger of bringing contagious diseases to the other clerks and employes, and allowing such diseases to spread in the community is said to be obvious, and has been manifested in recent cases. Moreover, a calling which is likely to require clerks and employes to be up at night, and to demand their prompt attention at all times, is regarded as inconsistent with the proper discharge of their duties in the Bureau. The issuing of the order was caused by a negro doctor, named Johnson, employed in the Bureau, attending a smallpox case, for which he was suspended. While no official notification has yet been issued, it is almost certain that a similar order will be made including the entire Interior Department, not only physicians, but those who engage in any outside work of any other character. This, it is said, will not apply to employes pursuing studies at night. The regular profession, to a man, naturally indorse this action of the Commissioner.

#### Hospital Notes.

**DR. B. D. EASTMAN** has been reappointed Superintendent of the Kansas Insane Asylum at Topeka.

**THE NEW FREE HOSPITAL** for women, at Brookline, Mass., was dedicated January 1.

**ST. MARGARET'S HOSPITAL.**—The plans for the new St. Margaret's Hospital to be built in Pittsburg, Pa., are nearly completed. The estimated cost of the building is \$250,000.

**THE NEW ST. LUKE'S HOSPITAL** at Davenport, Iowa, will be opened February 1.

**E. H. BENNETT.**—By the will of the late E. H. Bennett, of Janesville, Wis., the City Hospital of that place receives the sum of \$1,000.

**DR. FRONTZ**, of Williamsport, Pa., has been appointed resident physician to the State Reformatory at Huntington, vice Dr. D. P. Miller, resigned.

**SAN GABRIEL HOSPITAL BURNED.**—Advices from Montevideo report the destruction by fire of a hospital at San Gabriel (Brazil), by Brazilian troops. More than one hundred and twenty rebels perished. It is said that several who tried to escape were forced back into the flames by bayonets.

**SPRINGFIELD (MASS.) HOSPITAL ASSOCIATION.**—The annual meeting of the Springfield (Mass.) Hospital Association was held December 16. The total number of cases treated during the year was 338.

**JANE C. STORMONT HOSPITAL.**—The charter of the Jane C. Stormont Hospital and Training School for Nurses, at Topeka, Kan., has been filed. Mrs. Dr. Stormont donated \$10,000 toward building the hospital.

**THE MANCHESTER BROWN SURGICAL HOSPITAL** at Milwaukee, was formally opened December 21. The hospital will be devoted exclusively to surgical cases. The building has accommodations for fourteen private patients and thirty in wards. There are three operating rooms, sun rooms, a diet kitchen, and a dispensary.

**THE ILLINOIS STATE BOARD OF PUBLIC CHARITIES** has recommended special appropriations as follows, for the various State charitable institutions, for general improvements and repairs: Northern Hospital for the Insane, \$94,000; Eastern Hospital for the Insane, \$132,000; Central Hospital for the Insane, \$42,300; Southern Hospital for the Insane, \$47,720; Asylum for Insane Criminals, \$6,700; Institution for Education of the Deaf and Dumb, \$22,350; Institution for the Education of the Blind, \$26,500; Asylum

for Feeble-Minded Children, \$27,400; Soldiers' and Orphans' Home, \$15,800; Charitable Eye and Ear Infirmary, \$12,200; Soldiers' and Sailors' Home, \$53,500. Amounts asked for ordinary expenses for the next two years, and upon which the State Board is not called upon to pass, are: Northern Hospital for Insane, \$350,500; Eastern Hospital for Insane, \$580,000; Central Hospital for Insane, \$330,000; Southern Hospital for Insane, \$260,000; Insane Criminals, \$85,600; Institution for Education of Deaf and Dumb, \$210,000; Institution for Education of Blind, \$100,000; Asylum for Feeble-Minded Children, \$181,000; Soldiers' Orphans' Home, \$108,000; Charitable Eye and Ear Infirmary, \$54,000; Soldiers' and Sailors' Home, \$360,000.

**A NEW HOSPITAL** was opened at Beaver Falls, Pa., January 1.—A sanitarium for consumptives is to be founded at Liberty, N. Y., on a 200 acre tract of land secured for that purpose.—A pleasant incident of the holiday season, was the trip Christmas Eve, to four of the large hospitals of Chicago by the choir boys of Grace Church. A coach was furnished them by a generous liveryman, Mr. Payne, and the boys visited St. Luke's, Mercy, Cook County and the Presbyterian Hospitals, where they sang in chorus in the corridors, and greatly cheered the inmates of the institutions named.—The Annual Meeting of the Directors of Hartford, Conn., Hospital was held Dec. 20, 1894. Officers were elected as follows: President, Dr. Gurdon W. Russell; Vice-President, Jonathan B. Bunce; Secretary and Treasurer, Ward W. Jacobs; Executive Committee, Henry K. Morgan, Dr. Harmon G. Howe, Thomas Sisson; Committee on Finance, Jonathan B. Bunce, Henry A. Redfield, Henry C. Dwight; Librarian, Dr. William W. Knight. The following medical and surgical staff was appointed: Dr. Gurdon W. Russell, chairman; Dr. P. H. Ingalls, secretary; consulting physicians and surgeons, Dr. Gurdon W. Russell and Dr. Ashbel W. Barrows; visiting surgeons, Dr. George C. Jarvis, Dr. G. Pierrepont Davis, Dr. Harmon G. Howe, Dr. Melancthon Storrs; visiting physicians, Dr. Horace S. Fuller, Dr. William W. Knight, Dr. James Campbell, Dr. Edward K. Root; ophthalmic and aural surgeon, Dr. William T. Bacon; gynecologist, Dr. P. H. Ingalls; orthopedic surgeon, Dr. Ansel G. Cook; pathologist, Dr. Charles C. Beach; physician to the Old People's Home, Dr. Charles C. Beach. The Executive Committee explained the great need of further accommodations for nurses in the hospital, and the matter was referred to the Executive Committee with power to obtain plans for a building, and report to the directors.

## THE PUBLIC SERVICE.

**Army Changes.** Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Dec. 22, 1894, to Dec. 28, 1894.

First Lieut. A. N. STARK, Asst. Surgeon, is granted leave of absence for one month, to take effect upon his return to Ft. Sam Houston, Texas. Capt. JAMES D. GLENNAN, Asst. Surgeon, is relieved from duty at Ft. Sill, Oklahoma Terr., and ordered to Ft. Snelling, Minn., for duty at that post.

## ORIGINAL ARTICLES.

### HOSPITALS FOR THE INSANE—THEIR SCOPE AND DESIGN.

BY EDWARD F. WELLS, M.D.

CHICAGO.

Shall the State have the custody of all its insane, or shall certain classes be relegated to county care? Shall the State care for the acute and the chronic insane separately or shall the hospital and the asylum be combined in one institution? Shall employment, especially agricultural, be afforded the patients, and if so to what extent? Should epileptics be received into insane hospitals or should they be cared for in a separate institution? Should any class of the insane be "boarded out," as practiced at Gheel, in Scotland and in Massachusetts? What should be the scope and design of the modern institution for the insane? These are questions of perennial and engrossing interest to the social economist, the legislator, the executives of our States and to the public at large, and they will be considered, with especial reference to the present status in Illinois, as fully as the limits of this paper will allow.

#### STATE VERSUS COUNTY CARE.

Every person adjudged insane and requiring other than family care—acute or chronic, curable or incurable—should be under the control of the State. This is in the line of the opinions expressed by almost every one who has given the subject any special consideration. This entire ground has been so often gone over that another review may well be omitted and attention will only be asked to a limited field.

In the Report of the Board of State Commissioners of Public Charities, of this State, for 1890, page 104, occurs the following paragraph:—

"In the present report and chapter will be found accounts of ten naked patients, six men and four women, in Adams County; an insane woman confined in a pen in Bond County; an insane man in Boone County who is so troublesome that the keeper is paid extra for taking care of him; a miserable pen in DeKalb County; another in Franklin County; the insane department in Fulton County is declared a nuisance which should be abolished; in Jackson County three idiots, one of them an epileptic, are taken care of by an insane woman; in Jefferson County an insane woman sleeps alone in an outhouse; in Kane County, where fourteen insane are locked up, they make day and night hideous, and thirteen of them are disposed to denude themselves; in Knox County a naked man was found; in McHenry County the authorities are compelled to care for a man who can not even feed himself; the new insane department in Menard County already smells to heaven; the insane department in Montgomery County is condemned as unfit for use; the same is said of that in Shelby County; in Stark County two steel cages have been purchased for the insane, six by seven feet in size; in Wayne County the insane are filthy and ragged; Whiteside County has a naked insane woman on straw in a box."

Contrast this picture of county care, with its evi-

dent lack of medical supervision, of trained attendants, of facilities for classification and of suitable accommodation, with the intelligent and humane care given the insane in the four State hospitals, and there will be a ready appreciation of the force and sufficiency of some of the reasons upon which is based the opinion expressed.

There can be no doubt in the mind of any reasonable person that the circumstances which made it possible, in 1890, to frame such an indictment against the county care of the insane as that embodied in the quotation above given, were largely brought about by an evasion, by the managers of the State hospitals, of the last clause of Section 3 of an Act to regulate the State charitable institutions, in force April 15, 1875, which provides:—

That, in the admission and retention of patients, curable and recent cases shall have preference over cases of long standing, and that violent, dangerous, or otherwise troublesome cases shall have preference over those of an opposite description.

Human nature is much the same the world over, and so long as the laws permit insane patients to be returned to the counties by the State institutions, it will occasionally occur that trustees and superintendents of State hospitals, biased by self-interest, will allow patients such as those above described, to find their way back to the county asylums, the while harmless and easily cared for cases are being shown to visitors in the front wards of their hospitals. The remedy for this evil lies in prohibiting, absolutely, the care of the insane at the hands of every county in the State, with the possible exception, at present, of Cook. The prohibition might be omitted in exceptional instances, as for example, in the case of a mild, quiet, harmless, chronic pauper patient, who would be happier in the county almshouse, with its more elastic rules and greater freedom. In such a case the patient might be paroled to the county, the latter receiving a stipend from the State institution. He should, however, remain under the control of the hospital and should be visited at regular intervals by one of its medical officers. The hospital should also receive regular reports from the almshouse superintendent and physician and, at least once a year, a special report from the visiting agent of the Board of State Charities.

#### SCOPE OF THE INSTITUTION.

Certain classes of the insane require institutional accommodation of a different and slightly more expensive character than that which is amply sufficient for the ordinary chronic and incurable classes. Of the former may be mentioned the recent admissions; the acute cases; the weak and helpless; the sick and injured; the suicidal and homicidal; the filthy; those who denude themselves, etc. These require for their care and treatment wards of smaller size and a larger proportion of superficial space, together

with accommodations for a greater number of attendants—in short, *hospital* accommodation. The ratio of these to the other classes may be estimated at about one of the former to five of the latter.

Another group of cases would include the convalescents; the mildly insane; those with lucid intervals; the quiet; the well-mannered, etc. These may, for the most part, be treated with much freedom and require, so far as practicable, home comforts. Wards for their accommodation need neither hospital nor prominent custodial equipment, and only a small staff is required for their care. These classes constitute about one-sixth of the insane. The remaining two-thirds form the bulk of the chronic and incurable classes which need simply safe and comfortable asylum accommodations and care.

#### COMBINED OR SEPARATE INSTITUTIONS FOR THE ACUTE AND CHRONIC CLASSES.

Because a very large proportion of the insane are cases of long standing and hopeless it has been proposed, on many occasions, to care for these in separate institutions, cheaply constructed and conducted. This has been urged chiefly from an economic standpoint. In this connection it may be said that, as a general proposition, the cost of hospitals in the past has not been determined, in any great measure, by the character of the patients to be treated. It has been shown that the proportion of patients requiring special hospital facilities, which add but little to the expense, is only about one-sixth of the whole number. Is it not as reasonable to cheapen, as far as practicable, the construction of the wards for the remaining classes in connection with a general as with a special institution? Unhesitatingly, yes. As a matter of fact, the cost of these institutions is governed almost entirely by their size; the cost of the central plant; the character of the construction of the ward buildings; the technical knowledge employed in formulating plans and the efficiency of administration during construction. In erecting these great eleemosynary institutions there should be, in the matter of cost, a happy medium which should be earnestly sought. The expenditure of vast sums for useless accommodations, expensive administration buildings or costly embellishment should be absolutely interdicted, but if this wasteful extravagance is to be so severely deprecated, what words shall we use in condemning the criminal parsimony which erects flimsy fire-traps—lacking only time and opportunity for affording a horrible holocaust of the helpless insane wards of the State?

For practical purposes, insane hospitals, in their construction, may be divided into three classes:—1, ordinary, or quick burning construction; 2, slow burning, or semi-fireproof construction; 3, strictly fireproof construction. Justice, humanity and true economy should prevent the erection of buildings of the first class. Buildings of the second class may be allowable, provided the roofs and attics are made indestructible, the buildings not more than two stories in height and with a proper arrangement of rooms and exits. The recent and remote experience of this State; a correct appreciation of the obligations of the State to those whom it compels to inhabit these structures and a true economy point unwaveringly toward the third class as the proper one to be adopted. Fortunately the comparatively small additional expense of fireproofing buildings places this form of construc-

tion within the reach of, certainly the great State of Illinois. Generally speaking, it may be said of buildings for the insane that if they are very cheap they are not safe, and if entirely safe they can not be very cheap.

The first, and in many respects the most notable example of the establishment, on any considerable scale, of a separate institution for the exclusive use of the chronic and incurable insane was that at Willard, in New York. This asylum was opened in 1869 and its capacity gradually enlarged to 1,938. It has 904 acres of land and the estimated value of lands, buildings and equipment is \$1,541,000, or a per capita rate of \$795. The character of some of the construction may be inferred from a statement to the State Commissioners in Lunacy, in 1891:—

"A great deal was done during the year in the way of extraordinary repairs . . . The greater part of the foundation walls of detached group No. 2 were taken down and rebuilt." "A portion of the buildings of this institution was formerly the property of the old State Agricultural College."

In 1881 the State of New York established, at Binghamton, a second asylum for the chronic insane. This institution has 1,057 acres of land and a total valuation of \$759,375. The capacity is 1,050, thus giving a per capita cost of \$723.

These two asylums for the chronic and incurable insane were never satisfactory to patients, their friends or the medical officers of these and the other hospitals of the State, and in 1890 the project of the separate care of these classes was definitely abandoned by the Legislature. These hospitals now admit all classes of the insane and the other six State institutions retain their chronic cases. Dr. T. S. Armstrong, late superintendent of the Binghamton Asylum, in his report for 1888, mentions one of the objections met with as follows:—

"Many patients coming to this institution get the idea that they are incurable (as many of them are), and that they must remain here so long as they live. . . . To them it blots out all future prospects of recovery, and of a return to their home and friends. The mental, moral and physical effect of this is most unfortunate."

The Legislature of Massachusetts, in 1890 and 1892, authorized the building, at Medfield, of an asylum for the chronic insane, with a capacity for 1,000 patients and to cost, exclusive of expenses for land and administration, \$500,000. In order to keep within the appropriation, buildings were erected which, when nearly completed, were condemned as being too unsafe for occupancy. To make the fire-traps safe it was found to be necessary, at enormous expense, to replace the hollow wooden partitions by brick and terra cotta; the wooden supports of the floors and roof by iron beams and columns; to excavate for additional foundations; to provide additional means of exit in case of fire, etc. It is safe to say that these changes, together with the suits for damages which were expected to follow, will bring the total cost to a point far beyond the original estimates.

Pennsylvania began, in 1891, at Wernersville, an asylum for the chronic insane, with a capacity of 800. It has only recently been opened. The State Committee on Lunacy say, in their report for 1892, in considering its success:—

"The success of this asylum will greatly depend upon the appointment of the medical officer and his subordinates. All such officers should be shown to be in harmony with the theory of the separate care of the class for which the institution is intended."

The above four instances are the only examples, so far as my information extends, of the separate care, upon a large scale, of the chronic insane in institutions especially established for this purpose by any of the States. Of these, two have been abandoned after trials of twenty-two and nine years, respectively; one has been inaugurated within the past few weeks, and one is yet in process of construction.

The department for the chronic insane of the Worcester hospital and the county asylums of Wisconsin are not considered germane to this subject. Of the latter Dr. Walter Kempster says:—"The so-called 'Wisconsin plan' does not meet the conditions which an enlightened people demand, and sooner or later will be supplanted by some such management as the great State of New York has wisely adopted, and which I believe to be just and right."

The many arguments against the separate care of the chronic insane have been advanced so often and so forcibly during the past thirty years that they require at my hands no extended mention. It must be clear to any intelligent mind that every advantage of economical provision and maintenance, of comfort and occupation, which the chronic insane may have in separate asylums may be afforded them in hospitals for all classes; and further, that if any division of this kind will cost less for the chronic, it will add correspondingly to the cost for the care of the acute cases.

#### AGRICULTURAL EMPLOYMENT.

It has always been recognized, more or less fully, that occupation is useful for the insane. Thus the ancient Egyptians treated their insane by "amusement, occupation and healthful habits." It was occupation, especially in tilling the soil, that has made the Gheel colony a possibility and in the present century the advantages of having a large farm attached to hospitals for these classes have been fully appreciated since 1821, when Esquirol established his farm and called attention to the benefits derived therefrom. In this country it is a firmly established custom, from which reason and experience would not warrant a departure. The amount of land attached to a few of the leading hospitals, together with the proportion per patient, is herewith given:—

State.	Hospital.	Acres.	Capacity.	Per patient.
Massachusetts	Westborough	336	405	.83 acres
"	Danvers	255	863	.29 "
"	Northampton	493	470	1.05 "
"	Taunton	172	698	.24 "
"	Worcester	438	650	.67 "
New York	Utica	225	700	.32 "
"	Poughkeepsie	683	830	.76 "
"	Middletown	281	675	.41 "
"	Buffalo	203	525	.38 "
"	Ogdensburg	950	1,500	.63 "
"	Rochester	35	300	.11 "
Indiana	Indianapolis	160	1,524	.10 "
"	Evansville	160	400	.40 "
"	Richmond	309	434	.70 "
Minnesota	Rochester	480	630	.76 "
"	St. Peter	673	940	.72 "
Iowa	Independence	580	800	.72 "
Illinois	Jacksonville	160	1,180	.13 "
"	Elgin	510	1,100	.46 "
"	Kankakee	840	2,000	.42 "
Totals and averages, 21 hospitals		7,853	16,624	.47 acres

In my opinion an hospital intended for all classes of the insane should have at least one-half acre of good arable land for each patient, and double this amount would not be excessive.

In regard to the proportion of male patients—of mixed classes—who are able to work upon a farm, statistics give us no reliable information. As the result of much inquiry and personal observation, I am of the opinion that the number of these patients who are able to work and who would be benefited by

out-door employment is much larger than is generally supposed. It may be reasonably assumed that, in round numbers, 25 per cent. of hospital patients are obviously unfit for such employment, and of the remainder probably two-thirds could be advantageously employed in this manner. The spirit of our people is opposed to employing women at farm work, but an equal proportion of female patients may be given, in other directions, suitable and healthful employment. Useful employment is pleasurable and remediable to the insane while enforced idleness is a grievous punishment. Experience has long since demonstrated that properly regulated employment, together with an abundance of good food are prime factors in bringing about the result of a healthy, quiet and contented hospital. How often has not every one who has had practical experience with the insane seen restless, excited and sleepless patients become quiet, contented and sleep like babes under the influence of interesting occupation and a liberal dietary!

#### EPILEPTICS.

Epileptics who are insane should be cared for in hospitals for the insane, rather than in institutions for epileptics. If this point is conceded the erection of an institution for epileptics would not relieve the overcrowding in the hospitals for the insane. The fact, however, that the non-insane epileptics require a special care which can not be given them in the county almshouses, renders it highly desirable that such of these as are public charges should be given a State institution for their care. Such an institution should be as largely industrial as possible and might be made nearly self-supporting. According to the Report of the Board of State Charities for 1892, there were in the county almshouses of this State, 247 epileptics—140 males and 107 females. These, together with the purely epileptic in the Institution for the Feeble-Minded, and those awaiting admission into the latter, would be sufficient to fill a large institution.

#### BOARDING-OUT SYSTEM.

In the legendary period of history an Irish maiden fled to Flanders to escape the persecutions of a cruel father. She was here discovered by her unnatural parent and after suffering great indignities at his hands died and was buried in the chapel at Gheel, near Antwerp. The patient fortitude displayed by the young girl led to popular sympathy and, finally to her canonization as Saint Dymphna. By some means, not now clear, the belief became prevalent that miraculous cures of those affected with mental disorders were brought about by worshiping at the shrine of St. Dymphna, and as early as the seventh century the insane began making pilgrimages thence, hoping to find relief from their infirmities. These found entertainment, during their sojourn, in the houses of the neighboring peasants. In some cases their stay was greatly prolonged and in not a few instances they were abandoned by their friends and relatives. Many peasant hosts continued to keep these abandoned lunatics and, to lighten the burthen of enforced hostship the guest was required to assist in the peasants' work. In some cases, also, the poorer pilgrims were received as guests conditioned upon their performing services to pay, wholly or in part, for their keep. As time passed it became apparent to the peasantry that the care of the insane was prof-

itable to the community, both directly from the money paid by those able to pay and from the service rendered by those unable to pay in money. Unfortunately there accumulated a class too poor to pay and unable to work, and the burthen thus produced was relieved by the State paying an annual stipend for their keep. In this manner, after centuries of gradual development, has been formed the peculiar community of Gheel, wherein peasants receive into their homes, as guests, the insane and are recompensed therefor by a stipend from the State, the estate of the patient or by his labor.

In 1851 the Belgian government assumed control of the insane at Gheel, established an infirmary, provided for supervision and proclaimed regulations for the host-guest relationship of peasant and patient. The village embraces a large agricultural district and contains about 11,000 inhabitants, including 1,800 insane. The latter are, for the most part, accommodated in the homes of the peasants, not more than two of each sex being allowed in one house. The system seems to be locally satisfactory.

The success of the Gheel colony has led to the query whether this boarding-out system, modified to meet local requirements, might not be advantageously adopted elsewhere. Two lunacy boards, notably—those of Scotland and of Massachusetts—have answered this question affirmatively, and in both localities the system has been in operation long enough for us to judge its results.

In Scotland, where the boarding-out system has been in vogue a great many years, it has met with a fair measure of success. As a rule, patients are dispersed and are not concentrated in villages. In some instances, however, the harmless and incurable insane of the larger centers of population, as for example Edinburgh and Glasgow, are placed, to the number of ten to fifty in certain villages, but the practice is not considered desirable. Not more than four patients are permitted in any one house, but the actual number scarcely ever exceeds one or two. They are regularly visited by the visiting agents of the Lunacy Commissioners, and are under the control of these officers. So long ago as January, 1875, Sir James Coxe, one of the Commissioners, in a letter, says:—

"There is a growing difficulty in procuring and retaining suitable accommodations. . . . As a rule, the chronic patients removed from asylums are sent home to their parishes to live with friends."

This difficulty of finding suitable homes for those having no friends, willing to assume their care, has increased rather than diminished, and the Commission, in their report for 1884, make special mention of the fact:—

It was being forcibly recognized in Scotland that great care was required in the selection of households in which lunatics could be safely and advantageously "boarded out." It was realized that if the system was not to be discredited, more and extraordinary care would be needed in the sending from the asylums only suitable cases and finding for these congenial homes. It had been noted that where the family as a whole were uncongenial to the temperament of the patient the latter was often soon returned to the asylum in an excited and miserable state. It could not be doubted that, in some cases at least, mischief may be and is done by "boarding-out" harmless lunatics in households where they are exposed, not simply to privations, but to irritation and petty grievances hard to bear.

With the most strenuous exertions it has never been possible to get out, in this manner, any large

proportion of the insane, notwithstanding the well-known docility of the Scotch lunatic.

Massachusetts began, in 1881, to employ the "boarding-out" system in the care of a small portion of her insane.

During the first year 5 were "boarded-out;" during the second year the average number out, was, 21; third year, 60; fourth year, 113; fifth year, 94; sixth year, 126; seventh year, 142; eighth year, 168; ninth year, 164. Of the forty-seven thus sent out in 1892 forty-three were placed out for the first time. Of these, seven were returned to the hospital; two from persistent use of bad language; four for non-conformity to family life and requirements; and one because of frequent elopements. All of these, upon their return to institution life, immediately resumed their former quietude and readily acquiesced to existing rules.

Previous to making the change from institution to family life it is the custom to obtain the consent of the patient, if sufficiently intelligent; of the friends, and, if a pauper, of the overseers of the poor. Of this phase of the subject the Board of Lunacy, in their report for 1893, says:—

"It not infrequently happens that patients who appear suitable for family life object to the change, being fond of the regular and pleasant life at the hospital; or their friends think the change unwise; or overseers of the poor object, both on the score of economy and dislike of the system. More women than men are boarded out, and are generally preferred to men as boarders. Applications for boarders are filed, and the families are visited and carefully examined. After being placed, it sometimes happens that a patient has to be transferred several times before a suitable family can be found. During the last few years so many patients suitable for boarding-out have been removed from the hospitals . . . that but a small number has been left; these, from time to time have all been placed in families. In future the number will increase but slightly, only such cases occurring as naturally develop in the institutions."

In their report for 1894, the Board again expresses its opinion:—

"It will be seen that the number of insane boarded in families has somewhat decreased during the year, although persistent efforts have been made to place out all who appear suitable for such treatment."

Without special thought or design there has been developed a most admirable system of dispersion of the harmless chronic insane. I refer to the parole system, under which properly selected cases are sent home to the friends and relatives for immediate care, but remain under the jurisdiction of the hospital authorities. This necessarily has a narrow field, but it is fully as wide in its applicability as the boarding-out system. More attention is given this feature in some institutions than in others, but experience shows that if the authorities are earnest and persistent in the matter a reasonable proportion of the insane may be very happily cared for in this manner. It is probable that the extension of the system, if thought desirable, might be stimulated by paying the friends having the patient in charge, a sum equal to the cost of his subsistence were he in hospital.

The extent to which the parole system is utilized in a few State hospitals is shown in the following table:—

State.	Hospital.	Date.	Patients in Hosp.	At Home on Parole	Per Cent.
South Carolina . . .	Columbia . .	Oct. 31, 1893 .	796	37	4.64
Ohio . . . . .	Columbus . .	Nov. 15, 1893 .	1,197	106	8.85
Minnesota . . . .	Rochester . .	July 31, 1888 .	751	26	3.46
" . . . . .	St. Peter . .	July 31, 1888 .	954	25	2.62
Nebraska . . . . .	Lincoln . .	Nov. 30, 1890 .	326	13	4.00
Kansas . . . . .	Oswatimie . .	June 30, 1890 .	519	34	6.55
Illinois . . . . .	Kankakee . .	Nov. 19, 1894 .	2,090	78	3.73
" . . . . .	Jacksonville .	Nov. 16, 1894 .	1,222	10	.81
" . . . . .	Elgin . . . .	Nov. 18, 1894 .	1,115	30	2.69
" . . . . .	Anna . . . .	Nov. 19, 1894 .	853	32	3.75
Totals and averages, 10 hospitals . . . . .			9,823	391	4.00

It is thus seen that about 4 per cent. of patients carried upon the hospital registers are at home on parole.

Desiring to obtain definite information of the workings of this system in this State, I recently wrote the superintendent of each of the large public hospitals for the insane inquiring as follows:—

1. How many patients have you on your register?
2. How many are at home on parole?
3. Is any supervision exercised over patients out on parole?
4. Is any special effort made to get harmless chronic cases out on parole?
5. Do you approve the system?

To these questions the various superintendents courteously replied as follows:—

Dr. Arthur Loewy, of the Northern, reports 1,115 patients on the register, with 30 at home on parole. Paroled patients are supervised by correspondence with their friends. He always recommends the removal of harmless chronic cases whenever they can be cared for at home. He approves the parole system.

Dr. W. C. Lence, of the Southern, states that at his institution no supervision of paroled patients is exercised, except to instruct the friends to return them if they become worse. Special efforts are made to get patients out on parole, and he approves the system.

Dr. J. F. McKenzie, of the Central, says: "We exercise no supervision over patients on parole. They simply have the privilege of returning within the quarter without further legal proceedings. We are compelled to make considerable effort to get chronic cases sent home in order to make room for acute ones, as our institution is now, and has been for several years, full to overflowing. I think the system of granting parole is a good one."

Dr. Clarke Gopen, of the Eastern, says: "There is no special supervision exercised over patients who are out on parole, except when we send a special attendant to accompany them, which we do at times. There has been no special effort made to get harmless chronic cases out on parole. I think, however, that much could be done, not only to relieve the institutions, but for the benefit of the patients themselves by such efforts. . . . There are many patients in this Institution who, I think, could get on outside. . . . If the friends or county authorities could be induced to take a proper interest in them. . . . In answer to your fifth question, I would say that I do approve of the parole system, as it is difficult for us to say positively when discharging a patient whether such patient is in condition to bear the strain of ordinary life or not, and this can generally only be ascertained by trial. The quasi-criminal method of commitment in vogue in Illinois, makes it a very unpleasant thing for a half-recovered patient to be re-committed to an institution."

Dr. McGrew, of the Cook County Insane Asylum, says:—"We have 1,067 insane patients on the register. Very few are at home on parole. . . . No special supervision by the asylum authorities is exercised over patients after they leave the institution. Friends are required to assume all responsibility after patients are removed. . . . No special effort is made to get harmless chronic cases at home on parole; neither is any great objection made to friends removing them if they desire, because of the over-crowded condition of the wards. We believe that the insane, including the harmless chronic cases can be better cared for—with more advantage to themselves by the asylum system rather than at home."

The advantages of the parole system, as practiced, over the boarding-out system lie in the fact that the harmless chronic insane are in the hands of their relatives and friends, who are apt to take in them a more kindly interest than would strangers who were actuated solely by mercenary motives. The subject is one of interest and practical importance and well worthy of extended inquiry and careful consideration.

## THE TREATMENT OF EXTENSIVE BURNS.

Read before the Chicago Pathological Society, Sept. 10, 1894.

BY EMANUEL FRIEND, M.D.

CHICAGO.

Of all accidents which befall the human race none, in my opinion, call for more speedy and at the same time scientific treatment to alleviate pain, shock and subsequent infection than an extensive burn of the second or third degree, may it be caused by the mere flame, molten metals, boiling fats, hot water, steam and the like. It is not the object of this paper to go into the minutiae of etiology, symptomatology or pathologic anatomic changes characterizing the different forms and degrees of burns, but merely to hint at the anatomic changes taking place in the three gradations under which all burns are classified, and suggest a method of application of one of the oldest and best of therapeutic measures, namely water.

In burns of the first degree, dermatitis combustionis erythematosa, we get a mild hyperemia of the papillary vessels of the corium with consecutive paresis and passive congestion, which causes a slight swelling and redness. If an exudation takes place, and such is generally the case to a greater or less extent, a yellowish discoloration takes place; whether this is caused by the instantaneous application of a flame or by the heat of the sun, as in erythema solare, the changes are practically the same.

Burns of the second degree, dermatitis combustionis bullosa, are characterized by the appearance of bullae, and vesicles of various sizes from a pin head to the size of the palm of one's hand, and even larger, which are due to a serous exudation from the papillary and upper vessels of the corium separating in part or the entire thickness of the epidermis from the corium beneath. Generally, one sees innumerable blebs and bullae, which have ruptured from, no doubt, sudden over-distension from the rapid accumulation of serum and corpuscular elements; and also in consequence of the trauma, from the patient's hands, in his endeavor to extinguish the flame, we have great shreds of epidermis hanging from the corium.

Microscopically, the appearance is the same, whether the bullae or vesicles be caused by steam, fire or a vesicant. Through the kindness of my friend, Docent Riehl, of Vienna, in presenting me with a piece of tissue containing a vesicle, caused by a mustard plaster just previous to the death of the patient, I am enabled to give the following brief analysis of the same:

The tissue after fixation and hardening was stained with lithium carmine and picric acid, Zeiss ocular No. 3, obj. a. On either side of the field one sees the remains of the epidermis which has been lifted from the corium beneath, in this specimen having been ruptured in the center, possibly in process of preparation; still adherent to the under and outer surface one sees epidermoidal elements, indicating that just at this point separation had taken place in the stratum lucidum, while beneath and still adherent to the corium one sees intact rete malpighii with several layers of prickle cells. The center of the epidermoidal covering of this bullae, or rather vesicle is lost, but the corium with its obliterated papillae indicates that a complete separation of the rete malpighii and overlaying layers of epidermis had taken

place here. The contiguous papillæ are widened, the vessels dilated, while the connective tissue fibers are swollen and literally teased asunder by the exudate of serum, with its corpuscular elements; the latter having taken the lithium carmine stain quite markedly.

Burns of the third degree, dermatitis combustionis escharotica. In this degree the elements of the corium have suffered primarily from the continuous application of the heat, causing a mortification. According to the agent producing the same, the parts become charred, bronzed, or dried and leathery. Frequently one sees in the bronzed denuded surface, twig-like figures representing the coagulated and carbonized contents of the superficial vessels. The em-

beds, and a nurse in constant attendance. Through the kindness of Professor Kaposi and his first assistant, Dr. Lukasiewicz, now Professor of Dermatology in the University of Zürich, Switzerland, I was enabled to study these cases, by having access to this water bed ward at any and all times. Of all appliances and devices invented by man to relieve human suffering, I know of none which is entitled to greater credit than the Hebra water bed in the treatment of burns. It is practically an oblong tank seventy-eight inches long, twenty-eight and one-half inches wide, twenty-one inches deep, lined with zinc, shown in the accompanying plan designated (Fig. 1 a). Supporting this tank are two head posts three by two inches and forty-nine inches in height, and two at the foot meas-

inent medico-legal authority, E. Hofman, of Vienna, has shown that this injection of the vessels does not become apparent when the body of a murdered person is subsequently burnt, and also that the deeper tissues are afforded a considerable protection by the superficial layers of the epidermis and corium. Thus has been shown in the cremation of bodies to what a great heat, continuously applied, the tissues must be subjected before an effect is perceptible on the deeper tissues.

In Vienna, all cases of severe burning are taken to the dermatologic wards of the Wiener Allgemeine Krankenhaus, and cared for in a room set apart from the general wards, provided with seven Hebra water

beds, and a nurse in constant attendance. Through the kindness of Professor Kaposi and his first assistant, Dr. Lukasiewicz, now Professor of Dermatology in the University of Zürich, Switzerland, I was enabled to study these cases, by having access to this water bed ward at any and all times. Of all appliances and devices invented by man to relieve human suffering, I know of none which is entitled to greater credit than the Hebra water bed in the treatment of burns. It is practically an oblong tank seventy-eight inches long, twenty-eight and one-half inches wide, twenty-one inches deep, lined with zinc, shown in the accompanying plan designated (Fig. 1 a). Supporting this tank are two head posts three by two inches and forty-nine inches in height, and two at the foot meas-

port (Fig. 2 a) which can be raised or lowered to suit the patient's convenience, it being supported by a cog and ratchet arrangement, which is also found attached to the head windlass of the bed proper (Fig. 1 d).

At the head of the tank (Fig. 1 a), but separate and distinct from same, is a water receiver (Fig. 3) connected to the tank by a single pipe; merging into this receiver is both a cold and hot water pipe, coming either from a range or boiler, according to the source of the hot water. The temperature of the water is hence regulated here instead of at the main tank. Naturally, the large tank (Fig. 1 a) is supplied with an escape pipe and a safety escape to prevent an overflow. (Fig. 4 a, b.)

Fig. 1 E represents the side woodwork of the bed.

Upon the patient's arrival, orders are given the nurse to prepare the water bed, whose arrangement as you have seen is so simple that an inexperienced hand can prepare it in five minutes. The temperature of the water should be about 25 or 26 degrees R., and increased after the immersion to 32 or 34 degrees R.

The patient is carefully lifted onto to the blanket covering the mattress, which is swung above the water's surface, which should reach to almost one-third of the top edge of the tank. Almost at the instant the patient is immersed his heartrending shrieks and moans will subside, and if asked after five minutes, regarding his condition, will state that he now feels comfortable. If necessary, stimulants can be given and if the patient be laboring under intense shock, the water can be made somewhat warmer than that which would give the most comfortable feeling to the patient, being gauged by the hand and thermometer. To the face is generally applied a mask of linen, saturated in carroll oil. Within an hour or two, after the more acute symptoms have subsided, the patient is raised out of the water, catheterized, and the loose shreds of epidermis trimmed off and existing bullæ are tapped, care being taken not to remove the epidermal covering. Then the case is treated symptomatically.

As I have before stated, the object of these few lines is not so much the recommendation of the agent (as water has been used from time immemorial for the treatment of burns by both the laity and physicians) as it is the method of application, and consequently I would suggest the adoption of the water bed in all hospitals; possibly some ingenious member of the profession could suggest a plan by which the idea could be carried out in private practice, namely an apparatus adjustable to any bath tub.

I am certain that, had we been possessed of such an apparatus during my term of service at the Michael Reese Hospital, it would have been decidedly to the patients' advantage as well as our own.

The advantages claimed for the water bed are:

1. Relieving the patient almost instantly of the excruciating pain consequent on a severe burn, and following the application and removal of dressings afterward.
2. Producing more rapid cicatrization.
3. Relieving shock.
4. Preventing infection from erysipelas, pus micro-organisms, etc.
5. Prevention of amyloid degenerations due to the confinement of secretions by dressings.
6. Saving of expense of material and time in frequent dressing.

Patients may be allowed to follow this aquatic life for months and months, Kaposi reporting one patient having spent 385 consecutive days and nights in the water bed. They eat, drink, sleep and frequently gain considerably in weight in the bed. Not alone can burns be treated in this manner, but all forms of disease in which there is an extensive loss of epidermis as in pemphigus foliaceus, gangrene, or in chronic suppurating wounds.

## FACIAL BLEMISHES; A PLEA FOR THE STUDY OF THE SCIENCE AND ART OF COSMETICS.

BY EDWARD H. SCHAEFER, M.D., PH.L.

KANSAS CITY, MO.

There are many affections and defects of the body that demand the attention of the physician, who, in applying his knowledge of how to relieve and accomplish a cure, thinks he has done all that he is able to do.

There is still one branch left, belonging to the external part of the human frame, to which very little attention has been devoted and even arbitrarily excluded from the province of medicine, and that is the science of cosmetics. Physicians have always searched for hidden troubles of the human economy, diseases that are internal, not discernible by the eye, thereby entirely ignoring the outward conditions of man.

That branch of medicine, intimately connected with dermatology, the science and art of cosmetics, has been until recently a kind of *terra incognita*, being exclusively in the hands of empirics or non-professional persons. For ages, men, and women especially, have striven to enhance their personal attractiveness, augmenting beauty and symmetry to their forms. What remedial means and agents could be utilized in order to beautify face and body were the source of greatest speculation. Every one, man and woman, wishes to appear attractive, which naturally is as it should be, and all means that are employed in that direction to accomplish the desired end, are truly commendable. How often will a woman refuse to take medicine for some slight trouble, but can be persuaded with ease to do so, if she is reminded that some cosmetic blemishes might be the result. The impressions made upon us by persons depend largely upon their external appearance. Anything pleasing in its nature will be estimated in a favorable measure of opinion.

Our ideas relate more or less to esthetics, be it in the form of objects or persons. Women, knowing this perquisite to attractiveness have, since the remotest ages used all such remedies at their command that would heighten their bodily charms. We all are aware how concerned women often are about any eruption on the face, as for instance, acne, lenticular spots, chloasma and other facial blemishes too numerous to mention. Should this not in itself be a mild reminder of the necessity that the physician ought to concern himself more about those diseases of the skin that occur mostly upon the face and which often leave marks or imprints? How well could he apply his knowledge of the anatomy of the skin in making operations upon the face for tumors and other growths, so as to avoid leaving cicatrices. Young men and women may be seen walking along the streets, who have their faces literally disfigured

by acne, which often leaves its variola-like scars. If any one takes the trouble of observing he can see numerous people who have naevi, warts and pigmentations, such as freckles, chloasmata and port-wine marks on their faces and necks. How often do we not notice people whose faces are disfigured by scars, due to wounds that have suppurated a long time ago and have healed by granulation? Does it not appear to every thoughtful physician that there is still a wide field open to him in facial dermatology, if he only would try to do something in the line of removing or concealing facial blemishes by cosmetics? Wrinkles, the companion of approaching age, ought to be amenable to treatment, more so if they occur in the young.

Criminals often resort to the skill of surgeons in having certain marks removed from their faces in such a manner that not a vestige of former stigma remains.

Among the plastic operations for the relief of hare-lip, cleft-palate, the operation of rhinoplasty, we realize the aim of surgery to establish the art of cosmetics. All those remedial procedures, that are employed in the form of hot or cold baths, in order to incite perspiration, as well as massage and gymnastics, are used for the sole purpose of adding beauty to the skin and complexion.

We have so many agents at our disposal that could be employed in removing all disfiguring marks of the face and other exposed portions of the body, as for instance, electrolysis, excision with the knife, skin-grafting, the application of acids and alkalies and many other methods that the discretion and inventiveness of the physician may contrive.

There is one most prevalent cutaneous disease which appears so often upon the faces of young people of both sexes. I refer to acne with accompanying comedones. This skin disease is curable and ought to be successfully treated in a few weeks if the attention be given to it as it deserves.

Another sub-specialty, advertised by non-professionals, namely "capillurgy," the art of destroying superfluous hair, should be practiced only by physicians.

In the field of facial dermatology very much can be improved upon, in view of the fact, that by applying ourselves to that branch assiduously and studying the true pathologic conditions found present in cutaneous diseases, we are enabled to treat them more intelligently and effect a cure in many cases.

## BLOOD-SERUM THERAPY IN DIPHTHERIA

Read before the Chicago Medical Society, Dec. 3, 1894.

BY G. E. KRIEGER, M.D.

SURGEON TO THE CHICAGO HOSPITAL.

The blood-serum therapy of Behring, Roux and others is based upon the fundamental fact, that the blood of an animal which has been rendered immune against a certain disease has the power, when injected into another individual of the same or other species, to immunize the latter also against that disease. Suppose, for instance, we have a guinea pig immunized against tetanus or diphtheria bacilli and injected some of its blood into a rabbit, the latter would be protected for a certain length of time against infection of the germs or their poisonous products. Such products are especially dangerous and deleterious to the organism in diphtheria. If

one intends to immunize an animal against the effect of diphtheria bacilli it will be necessary to increase its resistance against the toxic products of the germs, the toxins.

An increased resistance and finally an immunity is obtained by applying systematically such doses of the poison to the animal as are sufficient to make the latter ill without causing its death. As the tolerance of the animal increases, so does the immunizing power of the blood-serum increase, which has been proven by Ehrlich in reference to the vegetable poisons, and by Behring with bacterial toxins. The way of proceeding for the purpose of immunizing animals against diphtheria as advised by Behring, Ehrlich and Wasserman is by hypodermic injections of at first very small, and later, gradually increasing doses of diphtheria cultures and diphtheria toxins.

The latter, according to Roux and Yersin, is prepared by inoculation of beef-tea in large flasks with diphtheria bacilli. After the flasks have remained in an incubator for three to four weeks 0.5 per cent. carbolic acid or 0.33 per cent. trikresol is added, by which the germs are killed and precipitated to the bottom of the flasks. The liquid then contains the toxin in solution. From this solution the toxin can be prepared as a dry substance or it can be used while dissolved in the fluid. The effect of injections of the toxin, is fever, local swelling and the production of antitoxin. The latter is found in the blood of the animal after each injection and increases in quantity with the number of injections. This treatment is continued until the animal possesses a sufficient quantity of antitoxin. In order to estimate its efficacy, it is necessary to tap the animal, from time to time, for a small amount of blood with which experiments are made on others. Behring and Kitasato were the first who observed that such antitoxin is able to neutralize the effect of toxin, when mixed in a tube.

The mode of valuation of the diphtheria antitoxin, as advised by Ehrlich is this; of a toxin, the efficacy of which upon a guinea pig is known, a certain quantity ten times the minimum fatal dose, which may be 1 gramme is mixed with a number of different quantities of the blood to be examined, for instance 0.5, 0.25, 0.15, 0.10 gr., and with these four mixtures four guinea pigs are inoculated. The result will be that the one which received the largest dose of the blood together with the toxin shows no reaction; the one that received the second largest dose will suffer from an acute local inflammation, followed by necrosis, but otherwise be not much affected. The third will probably become quite sick and the one which got the smallest quantity of blood will die in forty-eight hours, from the same dose of toxin as the other received. Hereby we can find out which amount of blood of the first animal is sufficient to neutralize a certain quantity of toxin, and so the value of serum can be established. This is simplified if one has a material of a standard strength with which to compare others. Behring and Ehrlich therefore, prepared a serum of which 0.1 gr. is sufficient to neutralize ten times the fatal dose of toxin (for guinea pigs) and this they called "normal therapeutic serum." Of such normal serum one cubic centimeter was called the equivalent for one immunizing unit. According hereto a serum, of which 0.01 gr. is sufficient to neutralize ten times the fatal dose, would possess

ten immunizing units or would be a ten-fold normal serum, and so on. Ehrlich's experiments with normal serum in children, affected with diphtheria, showed that at least five hundred immunizing units are necessary to effect a cure, that is 50 gr. if the material is a ten-fold normal serum, or 5 gr. if it is a one hundred-fold normal serum.

Has the value of the serum once been established by a series of experiments as stated above, the animal is tapped for a larger quantity of blood which, being received in sterilized vessels, is placed on ice until coagulation has been completed and the serum been separated as a clean yellowish fluid. This with 0.5 per cent. carbolic acid now presents the material to be used for therapeutic purposes. The most suitable animals for which the serum may be prepared are horses and goats on account of their susceptibility, as well as because of the large quantity they are able to furnish.

Before speaking about the administration of the so obtained serum upon man, an item worth consideration may be mentioned. It is a matter of experience that in different individuals, even of the same family, diphtheria can produce symptoms materially different from each other. One child may at first present the common picture of angina, with white plaques on the tonsils, but will recover after a few days of discomfort. Another child may have laryngeal membranes which necessitate tracheotomy or intubation. A third one may show from the beginning on, a serious affection of the tonsils, throat and nose, with obstructions by thick membranes and suppuration, from the effect of which it can not be saved even by early tracheotomy.

These different symptoms have all originated from the same cause, the infection with diphtheria germs, but for reasons not fully explained apparently, however, depending upon individual disposition, the infection is followed by so different local and general effects. To establish the diagnosis under such different circumstances it would be necessary to make microscopic examinations. The question now is, In what cases will the administration of serum save the child? Starting from the fact, that the antitoxin must be given in certain proportions to the toxins present and that it works effectually only if the organism has not too long been preoccupied by the toxin it is evident that a curative effect can only be expected in an early stage or in a milder form of the disease. If the diphtheritic process already affects the bronchii and lungs, so that even tracheotomy is of no avail, the serum-therapy will do no better. Neither can recovery be secured if complications possibly due to infection with other germs have set in.

Equally doubtful is the prognosis if the toxins have circulated for a longer period, say three to four days because their paralyzing effect upon the nerves and ganglia of the heart can no more be eliminated. As, however, the application of the serum is an entirely harmless procedure it seems to be advisable to use it even in advanced cases, provided they are not perfectly hopeless. This has been made a principle in the antitoxin treatment in several hospitals of Berlin, with the effect that according to the latest report, the mortality of all cases has been reduced more than 20 per cent. Of 121 cases treated with serum, reported by Director Koerte, 81 or 67 per cent. recovered, while the average during the past four years was but 55 per cent. recovery. This sta-

tistic does not show as good a result as it would if the gravity of the present epidemic is taken into consideration. Of 106 cases not treated with serum on account of impossibility to obtain it, only 46 per cent. recovered which, compared with the 67 per cent. would give a reduction of 21 per cent. due to antitoxin. Much better even than this are the figures if the cases are classified according to their gravity:

Of forty-three very severe cases the result was 41.8 per cent. recovery, 58.2 deaths. Of forty-seven medium grave cases the result was 70.2 per cent. recovery, 29.8 deaths. Of thirty-one cases with but slight infection 97 per cent. recovery, 3 per cent. deaths. Of forty-two cases in which tracheotomy had to be performed 47.6 per cent. recovered, 52.4 per cent. died against but 25.5 per cent. recovery in former years. Equally good results have been reported from other experimenters in Berlin and Dr. Roux in Paris. In regard to the effect of the injections it may be emphasized that they are absolutely innocuous. After 5,000 injections but 3 abscesses have been observed. The temperature does not increase nor are other general disturbances noticed. Locally, a tenderness or a harmless skin eruption is sometimes observed which, however, disappears after a day or two. Concerning the effect upon the tonsils and throat, the white plaques at first seem to spread after the injections; on the second day, however, the mucous membranes discharge the infective material and the swelling of the glands is also reduced. Besides this local effect, a change in the general feeling takes place soon after the injection. Pulse and temperature return to normal condition in early cases within the first forty eight hours, dizziness and general weakness disappear, and the children soon become convalescents.

In case of a renewed increase of temperature, one would have to conclude that complications as a suppurative process or pneumonia are in progress. The effect of serum injections will not be pronounced, as mentioned, if either complications, for instance scarlet fever, are already present while the serum is applied, or the case is so far advanced that the toxins can not be neutralized. In such cases we have always to look for paralysis of the muscles usually affected, in spite of the antitoxin. The most preferable place for the injections is on the lateral part of the chest, below the axilla, where on account of the soft subcutaneous tissue even large quantities are absorbed. The application is made with the usual aseptic precautions.

The antitoxin prepared as advised by Behring in the chemic works in Höchst-am-Main is put in different flasks, hermetically sealed, which bear on the label a mark as to the efficacy of their contents.

No. 1 contains a serum with 600 immunizing units, to be applied only in fresh cases on the first or second day.

No. 2 possesses 1,000 immunizing units to be used in more serious cases on the first or second day or in less serious cases of longer standing.

No. 3. possesses 1,500 to 1,600 units, and is meant for adults or very severe cases of children. I have here the samples of antitoxin which are equal to No. 1 and No. 2 of the German preparation. As a rule, but one injection is given. If this, however, is found ineffective, another one should be applied the next day. It is usually unnecessary to give an additional treatment, either locally or internally; the only

thing advisable may be to cleanse the mouth with weak antiseptic solutions.

In case the serum is not intended as a curative, but as a prophylactic, the strength and quantity required is considerable smaller. In the average, 100 to 200 immunizing units are sufficient to protect a healthy child against the infection. How long such protection or immunity lasts has not been fully determined, and Dr. Kossel advises a re-vaccination, after three weeks, if the child is still exposed to conditions which allow the infection. Such small doses, however, would be sufficient only in case the child was not already in the period of intubation, which would place it under the class of an early stage. It sometimes may happen that children were infected, but for lack of visible symptoms do not get an adequate dose, in which case not the serum would have to be blamed but the mistake in sizing up the case.

In conclusion, I wish to say that these few practical remarks do not pretend to cover the subject of blood-serum therapy, and those who are more interested in this subject I take occasion to refer to a monograph on "Blood-serum Therapy and Antitoxins," issued January 1.

Everything considered, I believe we are on the eve of a revolution in treating infectious diseases, and perhaps other constitutional diseases, the nature of which was heretofore not understood, for lack of microscopic and bacterial evidence.

1003 Columbus Memorial Building.

## HYGIENE OF THE ANUS AND CONTIGUOUS PARTS.

BY J. RAWSON PENNINGTON, M.D.

CHICAGO.

My object in writing this paper is to call attention to some of the most important points of practical every-day hygiene, as applied to the anal region; which, if we observed more carefully, would materially reduce the number of cases of ano-rectal diseases.

Failing to heed nature's call to evacuate the bowels, or, when heeded to attempt, as soon as seated, to force or hurry defecation by bringing to bear all the power of the diaphragm and abdominal muscles and force the fecal mass, which frequently contains seeds and other substances, with sharp edges, against and through the sphincter without giving it sufficient time to become thoroughly dilated, is a very common and frequent source of these troubles.

Dr. Eastman says: "This inordinate *vis a tergo* as often retards as expedites the matter, for human muscle, like human character, resists force, and in the case of the muscle under consideration, if overwhelmed by violence many times yields, at last, at the expense of its elasticity, the destruction of the hemorrhoidal veins and the laceration of the mucous membrane."

Now, recalling the fact that, in addition to this violence, the mucous membrane is everted during the act of defecation and that printed paper, hard and rough substances are frequently used as detergents, is it any wonder, with such favorable conditions offered for infection, contraction and development, that these diseases are so prevalent?

The use of printed paper, which is so universally and promiscuously employed, should be condemned, and the pernicious effects which are liable to follow its continuous employment, thoroughly impressed upon the laity.

Many of these papers and inks are poisonous. Quite a number of the inks contain nigrosin, arsenic, Paris blue (ferrocyanic acid), and other irritants, and some of them, being charged so highly with these elements, are labeled "poison."

Who is not familiar with the fact, that fabrics dyed with anilin dyes frequently produce violent irritation when brought in contact with the unbroken cuticle, and in some instances are sufficiently virulent to induce constitutional effects? This being true, is there not more danger in bringing these dyes in direct contact with the delicate and oftentimes lacerated mucous membrane of the rectum and anus?

The use of the above articles for detergent purposes, the former by mechanical injury and the latter by depositing irritants upon the mucous membrane, or cutaneous surface near the verge of the anus, induces an inflammatory condition terminating in abrasions, fissures, ulcerations, or, as Mathews says, "may produce such a condition of the mucous membrane as will ultimately end in hemorrhoids, etc."

These pathologic conditions, plus the temporary constipation they produce, place extra duty upon the external sphincter, which causes it to become developed out of proportion to the muscles involved in expulsion, wherein we have a very common cause of chronic constipation, and this frequently induces ulceration of the rectum, or sigmoid flexure, or both; and, because of the peculiar nerve supply to these parts, this condition may exist for months or even years, without either physician or patient suspecting it, and the individual is constantly treating for mental and nervous troubles, dyspepsia, uterine, kidney, heart and many other affections, which are purely reflex and can be relieved only by detecting and curing the rectal or sigmoid affection.

To illustrate the effect of minor anal irritation, I will briefly append one case:

Mrs. D., age 28, was referred to me in May, last, by my friend, Dr. Pynchon, to be treated for piles. I elicited that her bowels moved every fourth or fifth day only, and then after having taken from three to five compound cathartic pills, which it was necessary to follow with a large dose of salts or an enema. Examination revealed a spasmodic sphincter, hemorrhoidal tendency and a few small abrasions around the anus. I prescribed an aperient, a local application and advised frequent bathing of the anus. In a few days her bowels became regular, moving daily, and have continued so without further medication. Suffice it to say, that her general health materially improved.

The writer wishes not to be understood as saying that all vague or reflex troubles are due to rectal disorders; at the same time, however, he insists that emphasis must be placed on the undeniable fact, that *in the rectum exists the pathologic condition for more diseases than credit is given.*

Paper to be used as a detergent should be of a firm, smooth, soft and pliable quality and free from ink and other poisonous ingredients. There is nothing better in this line than pure tissue. Competition and demand, however, have caused the manufacturers to place upon the market many cheap, hard, stiff and inferior papers which are not only more expensive, but are not fit for use and should not be employed.

Another point, which I consider of very great importance, and one that is almost totally ignored, is regular anal ablutions.

Mr. Allingham in referring to this subject, says: "Many people seem to forget that the anus requires quite as much washing as any other part of the body."

Mathews, in referring to patients with a predispo-

sition to hemorrhoids, says: "These patients should be instructed that any irritant to the parts, such as printed paper, as a detergent, should be avoided, and above all that a cold ablution of the parts should be made after every act of defecation."

Kelsey, in such cases, advises the free use of cold water to the parts at least once a day, and further says: "This is the best tonic, astringent and anodyne of which I have any knowledge, and its habitual use would prevent a very considerable portion of all hemorrhoidal difficulties."

The same general advice is also given by Cooper and Edwards. Hence, the consensus of opinion of eminent authorities is, that the anus should receive frequent and regular ablutions, and the Bidet, Fig. 1, to which I shall presently refer, is superior to all other devices for this purpose. Yet, notwithstanding the preponderance of evidence, very few of our water-closets are provided with any appliance for this important part of the toilet!

The Bidet, above referred to, made by J. L. Mott & Co., is readily attached to any water-closet, and is so constructed that the anus and contiguous parts may be thoroughly drenched with hot, cold or tepid water after each evacuation of the bowels; and by attaching a vaginal pipe, since the force of the jet and temperature of the water are easily controlled, it becomes a useful apparatus for vaginal injections.

PLATE 1098-G  
Copyright, 1894, by THE J. L. MOTT TOOL WORKS.

A simpler arrangement, however, and one that would answer most all purposes quite as well, is a miniature wash bowl fastened to the wall or otherwise, at the rear and on either side of the closet basin, near the seat. This basin is supplied with hot and cold water and has a waste connected with the closet bowl, that can be raised or lowered at will. From the tap, lint, fabric or tissue paper may be dampened for use, after defecation, or the waste closed and the bowl filled with water which may be medicated before using, if desired. No well appointed private water-closet is complete without some provision being made for this part of the toilet.

I find, upon inquiry, that many ingenious ways are devised for cleansing and bathing this portion of the human anatomy. Some soak a few pieces of toilet paper in the wash bowl of the bath-room; others flush the closet basin, then dampen some paper, for cleansing the part, in the water with which it refills. In both instances it is very inconvenient, and in the latter there is much danger of infection, and I should be inclined to look upon it as a rather unsavory procedure at best.

Heeding nature's call to evacuate the bowels, using paper of the quality above advised and keeping the anus and contiguous parts clean, by daily ablution, guards against chafing, filth, eczema, pruritus, fistula, piles, constipation and a host of other troubles, which are a frequent cause of many chronic constitutional diseases. It also prevents soiling of the linen, which to the sensitive and delicate-minded person is a source of great annoyance.

103 State Street.

## THE RIGHTS AND DUTIES OF MEDICAL WITNESSES.

Read before the Mississippi Valley Medical Association, Nov. 21, 1894

BY HON. W. S. KERR.

MANSFIELD, OHIO.

The scope of this paper carries us to the gate of medical jurisprudence, and a little beyond, but I do not enter far its inviting domain. I deal largely with the rights of physicians and surgeons when subpoenaed as expert witnesses, and with the duties incumbent upon them as members of a learned and honored profession when they are called upon to testify as medical experts.

Medical witnesses have been extravagantly eulogized and unmeasurably condemned by courts and law writers. They merit both the eulogium and the condemnation. When they traffic in their evidence and appear as hired advocates the condemnation is just; when they appear as members of a great and enlightened profession, to aid in the administration of the law, and testify conscientiously, no tribute is undeserved.

The weight of medical expert evidence depends upon two qualities: 1, the skill, learning and experience of the witness; and 2, his honesty. The latter quality can be and should be alike in all; the former, in the nature of things, must vary and differ in degrees almost infinite in number. A physician whose practice has been confined to the small towns or the country could not be an Ericsson, nor one of three years' experience an Agnew. But all are admitted to testify to those things which they have studied and practiced, and the cause of truth and justice demands that according to their lights they should testify the truth, the whole truth and nothing but the truth. It should be recollected that not only the spirit but the form of the oath covers an opinion as well as facts testified to by expert witnesses. I do not want to lecture or read a homily on duty to the medical profession, but the following extracts from court opinions and eminent law writers will not only justify the few observations I have made, but will also show how your high standard has been lowered here and there along the line, by testimony calling out these criticisms. But that you may see how well the line has been held at other points, I quote alternately censure and praise, or, as earlier suggested, condemnation and eulogium.

A Scotch judge of that rugged integrity characteristic of his people, once said to a jury, referring to the medical evidence submitted on the trial: "The evidence is as unsatisfactory as any I have ever seen. It leaves on the mind the distressing impression that the science of medicine is simply the science of guessing and experts. Different doctors with equal confidence and equal dogmatism, express contrary opinions upon the same condition of things. I advise

the jury to exercise their common sense, throw overboard the medical opinion and go by the facts."

A Texas court once said: "The opinions of medical men are received with great respect and consideration, and properly so."

Judge Redfield in his treatise on the law of wills says: "Medical experts are beginning to be regarded much in the light of hired advocates, and their testimony nothing more than a studied argument in favor of the side for which they have been called. So uniformly has this proved true, in our limited experience, that it would excite scarcely less surprise to find an expert called by one side, testifying in any particular in favor of the other side, than to find counsel on either side arguing against their clients, in favor of their antagonists."

The Supreme Court of Pennsylvania says: "It is well settled that the knowledge and experience of medical experts is of great value."

An Ohio court said in reference to evidence in a murder case: "It would be but a farce to try such a question upon the strength of medical opinions, and to regard the weight of evidence always on the side which produced the greatest number."

The Supreme Court of North Carolina says: "The opinion of a well-instructed and experienced medical man upon a matter within the scope of his profession, and based on personal observations and knowledge, is and ought to be carefully considered and weighed by the jury in rendering their verdict."

The Illinois Supreme Court says: "These doctors were summoned by the contestants as 'experts' for the purpose of invalidating a will deliberately made by a man quite as competent as either of them to do such an act. The testimony is worth but little, and should be received by courts and juries with great caution. . . . It must be apparent to every one, but few wills could stand the test of the fanciful theories of dogmatic witnesses. . . . In such cases the opinions of neighbors, of men of good common sense, would be worth more than all the experts in the country."

The Ohio Supreme Court says: "Medical testimony is of too much importance to be disregarded."

Mr. Justice Grier, of the United States Supreme Court, said in delivering an opinion: "Experience has shown that opposite opinions of persons professing to be experts may be obtained to any amount."

The Georgia Supreme Court in speaking of medical evidence says: "It is entitled to great weight and consideration."

Judge Campbell, of the Michigan Supreme Court said: "The experience of courts with the testimony of experts has not been such as to impress them with the conviction that the scope of such proofs should be extended."

Thus has the shuttle of criticism, favorable and adverse, gone to and fro, weaving in the warp and woof of jurisprudence, the history of the medical witness. In the court-room he has won laurels for his profession—in the court-room he has brought reproach upon its fair name and fame. But it should be remembered that the medical expert is not the only expert whose testimony has been the subject of unfavorable judicial comment. Other experts appear quite as frequently as do physicians and surgeons, and when their evidence has been afflicted with the same vice it has been similarly characterized.

To avoid this just censure, opinions should be re-

garded as facts stated under the solemnity of an oath, and not as arguments to be urged in behalf of the side calling the witness. Opinions can not be measured in reference to their soundness, as facts can be squared to accord with the truth; there must be more latitude to give room for the difference in mental processes and impressions, but they have boundaries, or else there is no exactness in medical science. Exactly opposite opinions upon the same hypothesis proves one of two things—either that the witness lacks veracity or knowledge, or that the science is too elastic to be the measure of important rights.

Courts have been called upon to unfavorably criticize medical witnesses in respects other than in reference to opinion evidence. An investigation involving the condition and position of organs which can be examined physically and ocularly, ought not to differ materially in the result. The evidence of such examination and result presents facts and not opinions. A case illustrating this point, and in which I was engaged as counsel, came under my own observation. A woman sued a municipality for damages. She claimed to have prolapsus of the uterus from a fall upon a sidewalk. During the trial eight physicians examined her—four at one time and four at another, but all within an hour or two. Four testified that her condition, in respect to the matter complained of, was entirely normal.

The other four, and their examination had been contemporaneous, testified as follows: One said he found the position of the organ abnormal in that it leaned too far back; the second that it leaned too far to the right; the third that it leaned too far to the left, and the fourth, a Nestor in the profession, said he found it too straight up.

Another case tried recently in an Ohio court illustrates how physicians may fall short in making the test which more than any other would measure the capacity, which is always the desideratum in such investigations. An application was made for the appointment of a guardian for a man who, in the meridian of his powers, was one of the most celebrated physicians and surgeons in Ohio, upon the ground that he had become an imbecile, and was incapable of managing his business. Three of the most celebrated and able mental alienists in the State testified to his soundness of mind and his capacity to do business. Their investigations, although made with ample opportunity, were limited to conversations upon subjects relating to events long past or about items of property which he had possessed for years.

An order of the court was made to examine the alleged imbecile and such examination was made. Two very simple tests did more to solve the question of incapacity than all the expert evidence. He was told to add a column of five figures. The first three were added correctly but he could add no farther. He was next given \$1.77 in change, consisting of seven or eight pieces and although he was able to designate the pieces, after considerable effort, he was unable to tell the aggregate. A man capacitated to do business should be able to add five figures and count a few pieces of money.

The cases in which the physician is called upon to aid the law are legion. If I were to undertake to enumerate them, the schedule itself would extend beyond the reasonable limits of a paper. Judicial

history shows that the physician as an expert witness, shines brightest or suffers the most serious discomfiture in cases of insanity and poisoning. Both of these afford a broad field for the exhibition of brilliant professional learning and acumen, and in legal investigations usually attracting large public interest and attention. They are fields worthy of any man's conquest even though he has to burnish his weapons by the light of a midnight lamp.

It should be recollected, also, that it is only in doubtful cases where the medical witness becomes an auxiliary to the law. He should not only be able to describe and classify the subject about which he testifies, according to the science of his profession, but he must bring his knowledge down to the comprehension of the twelve ordinary men who sit in the jury box. Because, however learned he is, if those whom he is to enlighten fail to comprehend him he has failed of the object and purpose of his being a witness. In measuring the duty of the medical witness it should be borne in mind that the majority of medico-legal questions are beyond the field, and lie far outside the every-day path, of most physicians. Nineteen-twentieths of their practice, medical and surgical, never relates to a matter which is the subject of litigation. It requires study, much study, to be a giant in any profession. Those who wait until the case presents itself, before fitting to try it or treat it, gather only withered leaves and faded flowers for their victor wreaths. That the daily practice of a doctor does not bring him into contact with the insane, is no reason why he should not possess, at least, the book learning of the subject. He may not be called once a year to treat a case of poisoning, yet he should know the various poisons, their peculiar effects and symptoms and be able to make the distinctions which science enables those to make who have tarried long enough at her fountains. It is to the advantage of a physician, if he never earned a dollar in this field, to be accomplished in legal medicine. It is a part of his profession and one who succeeds in a profession is one who explores with the lamp of industry its every branch and recess, and who comes to the discharge of its every duty with a mind capable of not alone comprehending, but of applying correctly its principles.

Necessity brought into requisition the medical expert. Frequently the courts would encounter questions of fact which all the knowledge of lawyers and judges and the common sense of juries could not solve satisfactorily. If those questions related to the human mind or body, who better could assist in making light that which was dark and mysterious, than the learned physician? So he was added as a spoke in the wheel of justice, or a wheel in the machinery of the law.

Mental alienation is a broad and inviting study. Men have spent their lives and become famous in the field and yet have not conquered half its difficulties nor solved half its mysteries. But this should not discourage the physician from devoting a little time, stolen from the daily grind, to its study. Like the bread cast upon the waters it will come back to bless him. Any doctor may be subpoenaed at any time to testify as a medical expert. Doctors as well as lawyers, and perhaps members of other professions, are judged by a standard fixed by a misconception and this misconception is deeply rooted in the common mind. In general under-

standing, both law and medicine are supposed to be made up of certain fixed and unvarying rules, which when applied will solve every question and dispute and determine every diagnosis and the treatment. It is further believed that every doctor and lawyer should be able at any moment to pick up one of these rules, as a carpenter would his measure, and settle the question or tell the disease at sight. We know that these are mistaken ideas. I am not competent to speak as to medicine, but as to law, it is not so much to know the law as to know where to find it. But in general estimation a doctor, when put on the stand, is expected to shed broad light upon any subject connected with medicine and if he is not able to do so or at least appears not to be able, not only his professional dignity but his professional standing and usefulness suffer.

Physicians are brought into court to testify as to the identity and ages of persons. The Tichborne case, as to the identity of the claimant, is one of the most interesting judicial records of the world. They are asked to give opinions as to probable survivorship where persons have died at near the same time and the course of inheritance depends upon the order of death. They are required to testify as to the age of puberty and to determine the most delicate and important questions in cases involving capacity to commit rape and paternity proceedings. In cases of criminal abortion, multitation, homicide, infanticide, defloration, wounds, impotency, sterility, pregnancy and in scores of other cases and upon scores of other questions, the physician is a valuable, an indispensable auxiliary in legal proceedings, civil and criminal.

A learned legal authority says: "The jury are to be enlightened in every possible way, and as they are not selected with a view to their qualifications to try the particular issues before them, but as men possessing the ordinary qualifications of mankind, when questions arise to be determined by them, involving an acquaintance with facts not coming within the ordinary range of human experience, skilled witnesses are permitted to enlighten them. The true rule is that when the subject to be investigated so far partakes of the nature of a science or trade as to require a previous course of study or habit in order to attain a knowledge of it, opinions of experts are admissible."

In legal controversies, turning upon, or involving the condition of mind as to soundness or unsoundness, the most important as well as the most difficult questions are largely determined by medical evidence. The physician is able, as no one else can, to physically and mentally measure the man. A man may not be able to manage his business affairs and still be responsible for crime. In criminal proceedings the supreme test is the ability to distinguish between right and wrong. This would seem a very simple and easy rule, but in its application to actual cases it calls into requisition all the acuteness and learning of both professions and in spite of all their acuteness and learning many an insane person has been executed for crime and many an offender has escaped just punishment upon the mistaken finding that he was insane. And it is no reflection upon law or medicine that this should be so. The most difficult problem with which courts and lawyers and doctors have to contend is that of real or alleged mental aberration in criminal cases and especially in capital cases. Many cases present the defense of

insane impulse. The person charged being concededly sane, immediately before and immediately after the commission of the act. Such was the shooting of Key by Sickles. Sickles was a Congressman and eminent in public life. Key had done him a great wrong. Upon sight of Key and under the impulse of his wrought up feelings the latter was shot dead in one of the public parks of the National Capital. The defense was that his condition of mind at the moment rendered him incapable of controlling the natural impulse to destroy the destroyer of his home. He was acquitted.

The Mary Harris case tried in Washington during the war was a celebrated case and presented clearly the difficulty, which medical experts encounter and, as well, the duty which they must discharge when a life, especially that of a woman, is at stake. The defendant shot a man to death in the Treasury Department and her defense was insane impulse. She was defended by most able counsel, among them being Senator Voorhees, then a Member of Congress. Eminent medical experts testified on both sides. While she was imprisoned, Mrs. Lincoln sent her a bouquet of rare flowers and within a year or two last past she was married to her senior counsel. She was acquitted upon the ground that at the moment of the shooting she was incapable of controlling the impulse under which she destroyed a human life.

A further illustration of this kind of evidence is in cases where, although the person charged with an offense is insane, it is claimed that either he still retained enough mental power to distinguish between right and wrong, or that the act was committed during a lucid interval. The question of responsibility may turn upon a brief interval of time.

Again, in civil cases, some of the most important, delicate and interesting questions, as to mental capacity, have arisen in contests of wills. The mental capacity is frequently complicated with undue or illegal influence and thus compounded make contests in which fame may be achieved by medical experts.

And still again, difficult questions as to mental capacity arise in proceedings to appoint guardians for persons alleged to be imbecile or insane. I believe medical authorities define an imbecile to be one idiotic but not born such. An old legal authority provided this test: "A person who has understanding enough to measure a yard of cloth, number twenty correctly or tell the days of the week is not an idiot in the eyes of the law." But in these days of asylums for the feeble-minded, institutions in which idiots are taught to do these things and many more, this test of responsibility or capacity would hardly be received as conclusive. And in all such cases judges, calling to their aid medical gentlemen as expert witnesses, must unravel the tangles.

Cases in criminal poisoning usually have about them the interest of mystery. In a great majority of these cases the evidence to convict or exculpate must come from the medical profession. The most important witness is usually the attending physician, and very much depends on how carefully he has noted and how clearly he can describe the symptoms. The chemist can analyze in search of the poison, but only the doctor can preserve the symptoms and appearance.

Doctors are frequently called into court, not simply as witnesses to give an opinion but to testify

to technical facts, the knowledge of which was acquired by them in the confidential capacity of attending as a family physician and in aid of or against persons thus employing them. Under the common law the communications made by patients to their physicians were not privileged. Most of the States by statute have provided that such communications shall not be given in evidence if the patient objects. The privilege is that of the patient and not of the doctor. But in order to exclude them they must be made about something necessary to be disclosed in order to prescribe the remedy or treatment.

I have reserved for the last, a brief reference to the law regarding the right of medical experts to receive or demand extra compensation before testifying. If they are subpoenaed to testify to facts which came under their personal observation, their rights are not different from those of any other witness. They are bound to obey the summons of the court and if they neglect to do so, they would be subject to punishment as for contempt of court. I think, as a general proposition and in the first instance, physicians are obliged to appear in court when subpoenaed and paid or offered the ordinary fee, and that their right to raise the question does not present itself until they are propounded questions calling for opinion or scientific evidence and then the question arises hereinafter discussed. This may seem to fall short of what an expert ought to be able to demand before going to court, but the reason of the proposition lies in the difficulty of determining beforehand the kind of evidence to be elicited. If it was conceded at the outset that opinion or expert evidence alone was to be sought, then I think the right to demand extra compensation would exist before answering the subpoena or at least before going upon the stand.

Some of the States by statutory provision, have settled this question. North Carolina as follows: "Experts when compelled to attend and testify shall be allowed such compensation and mileage as the court may, in its discretion, order."

Iowa as follows: "Witness called to testify only to an opinion founded on special study or experience in any branch of science or make scientific or professional examination, and state the result thereof, shall receive additional compensation, to be fixed by the court, with reference to the value of time employed and the degree of learning or skill required."

Rhode Island as follows: "In addition to the fees above provided, witnesses summoned and testifying as experts in behalf of the State before any justice of the Supreme Court, trial justice or coroner, may be allowed and paid such sum as such justice of the Supreme Court, trial justice, or coroner may deem just and reasonable; provided, that the allowance so made by any trial justice or coroner, shall be subject to the approval of a justice of the Supreme Court."

Indiana has settled the matter the other way and as follows: "A witness who is an expert in any art, science, trade, profession or mystery may be compelled to appear and testify to an opinion as such expert, in relation to any matter, whenever such opinion is material evidence relevant to any issue on trial before court or jury, without payment or tender of compensation other than the per diem and mileage allowed by law to witnesses, under the same rules and regulations by which he can be made to appear

and testify to his knowledge of facts relevant to the same issue."

In States where no express provision has been enacted the question is still an open one, unless some court of authority has fixed a rule. Some of them have, as hereinafter stated. No expert is required, whatever the rule is, to make examinations and prepare to testify in behalf to a party to a suit without such compensation as may be agreed upon. He might be required to do so if appointed by a court as a commission or committee in cases where the court had authority to make such appointment. He can not be compelled to attend the progress of a trial in order to enable him or qualify him to give opinions as to questions involved.

The reasons are all in favor of extra compensation. Authoritative writers on medical jurisprudence have set them forth as follows: I quote from Ordronaux: "It is evident that the skill and professional experience of a man are so far his individual capital and property that he can not be compelled to bestow it gratuitously upon any party. Neither the public, any more than a private person, have a right to extort services from him, in the line of his profession, without adequate compensation. On the witness stand, precisely as in his office, his opinion can be given or withheld at pleasure; for a skilled witness can not be compelled to give an opinion, nor committed for contempt, if he refuse to do so."

I quote next from Beck's "Medical Jurisprudence:—" "If the duties on which I have enlarged are important to the community, in promoting the proper administration of justice, ought not the individuals engaged in them to receive adequate compensation? I advert to this not only because it is just in principle, but because it would remove all imputation of volunteering in criminal cases; no one can refuse being a witness when legally summoned; every one, I presume, may decline to dissection of a dead body, or the chemic examination of a suspected fluid and yet there is not, I believe, an individual attending on any of our courts, who is not paid for his time and services, with the exception of such as are engaged in these investigations."

These authors are physicians and it may be reasonable to subtract a little from their enthusiasm, but notwithstanding, they state cogently reasons which ought to determine the rule. A good deal of learning has been expended in discussing whether the rule should rest upon the theory than the time of an expert was more valuable than that of an ordinary witness, or that upon the theory that his opinions, skill and experience are his property of which he can not be deprived without adequate compensation. The latter theory has prevailed universally where extra compensation has been authorized and it is the only tenable basis.

In a Massachusetts Federal Court in a criminal case, the district attorney moved to attach a witness as for contempt, who had failed to appear when subpoenaed as an interpreter. It is not an exact parallel but the reason is the same. The court declined to issue the writ and in the refusal is reported as saying: "A similar question has heretofore arisen and I have declined to issue process to assist in such cases. When a person has knowledge of any fact pertinent to the issue to be tried, he may be compelled to attend as a witness. . . . But to compel a person to attend because he is accomplished in a particular

science, art, or profession would subject the same individual to be called upon in every cause in which any question in his department of knowledge is to be solved. Thus the most eminent physician might be compelled, merely for the ordinary witness fee, to attend from the remotest part of the district, and give his opinion in every trial in which a medical question should arise. This is so unreasonable that nothing but necessity would justify it."

One of the Federal Circuit Courts of this State (Arkansas) has decided the question in favor of the right to demand extra compensation before testifying to matters of expert knowledge. The court said: "The skill and professional experience of a man are so far his individual capital and property that he can not be compelled to bestow them gratuitously upon any party."

The Court of Appeals of Texas held the opposite rule upon the peculiar facts of the case. A physician was placed upon the witness stand and testified without objection to the facts which had come under his personal observation; when it came to his opinion as to the cause of the man's death he declined to answer without other compensation than the ordinary witness fee. The trial court sustained the physician, but the Court of Appeals held that inasmuch as he had already made the *post-mortem* examination he should give his opinion.

The Supreme Court of Indiana, before the passage of the statute denying the right to extra compensation, decided the question the other way, and in the opinion used the following language: "When a physician testifies as an expert giving his opinion he is performing a strictly professional service. So does the lawyer, when he performs any services in a case. The position of a medical witness testifying as an expert, is much more like that of a lawyer than that of an ordinary witness testifying to facts. The purpose of his service is not to prove facts in the case, but to aid the court of jury in arriving at a proper conclusion from facts otherwise proved."

The English rule is well settled in favor of extra compensation. Justice Maule in one case saying: "There is a distinction between the case of a man who sees a fact, and is called to prove it in court of law, and a man who is selected by a party to give his opinion on a matter on which he is peculiarly conversant from the nature of his employment in life. The former is bound as a matter of public duty to speak to a fact which appears to have fallen within his own knowledge. The latter is under no such obligation; there is no such necessity for his evidence and the party who selects him must pay him."

Alabama has denied the right; other States may have done so, but the cases have not come under my observation. Upon the reason of the thing one wonders why courts have divided upon the question. An expert is one who by study and practice, skill and experience has acquired peculiar knowledge of a certain subject or matter. He arrives at his knowledge by a process akin to that through which property is accumulated, and it is as valuable as property. The latter receives the protection of constitutional provision, and is guarded as sacredly as life and liberty. Yet knowledge, by these adverse decisions, is treated as commons upon which judicial stock may graze at pleasure.

The evidence of an expert should be compensated for commensurate with its value. In criminal cases

the amount should be fixed by the court, in civil by agreement between the expert and the party calling him. The medical expert should never have his opinions for sale. Fidelity to his profession and its great principles should be his pole star. Medicine is the greatest of the worldly professions. It deals with life and health, the dearest possessions of this sphere. For years, if not in substantial honors yet in general estimation, it has been honored above all. Its members have ornamented the most exalted stations, and in its daily work, without herald or drum beat it modestly performs its great task in life. I am highly honored by being admitted, for this brief time, within the precincts of your order.

CHAPTER III.

**Algid Form:**—"As a general rule, the vascular action was much below par in the algid form. I have observed cases in which the radial pulse was imperceptible for days; more commonly, however, the pulse at the worst, though excessively feeble, was not altogether obstructed, and by a delicate and practiced finger it could be felt and counted. Its rate was variable, more commonly below than above 100 per minute. I have noted it at 80, very fine, thready, weak and readily extinguishable, and at almost all intermediate rates to 120, with much the same character. The cardiac action was very feeble. I have not observed any diminution in the relative proportions of the first and second sounds of the heart; they were often diminished in tone and force, but preserved their relative characters of duration and intensity. I have not observed any want of accordance between the cardiac action and that of the arteries in the algid form, such as I shall have to speak of subsequently when treating of some of the other forms. In general, in this form the radial pulse could be taken as a measure of the cardiac action. When the pulse was feeble, the heart was likewise proportionately so. There was no exception to this rule, as my experience of the cases goes (p. 260).

**"Sthenic Form:**—This class of cases generally exhibits from the outset a remarkable elevation of temperature. It is common to find an increase of 3 degrees, 4 degrees or even 5 degrees Fah., and in some instances an increase of nearly 7 degrees has been observed. We have noted the thermometer in the axilla at 102 degrees, 103 degrees, 104 degrees, and in some instances it nearly touched 105 degrees Fah. This limit I have not actually seen reached in any case, though the mercury in some instances rose considerably above 104 degrees. (The instrument employed, an English one of the kind commonly used for hospital purposes, did not admit of more minute or accurate reading than by whole degrees (p. 266.)

**"Rate of the Pulse in the Sthenic Cases:**—The pulse, though often full and expanded, and occasionally hard and thrilling in this form, commonly ranges but little above 100 or 110 beats per minute. I have

noted it in some cases at 112, 114, and in very rare instances so high as 120. In general, when the pulse runs above 115, the case passes into a low and typhoid state; on the other hand, I have seen well-marked pyrexia with a pulse at 60. It has fallen to 100, 90, 80, and even 70, and in two instances to 60, without very well marked diminution of the other pyrexial symptoms; in these latter instances it has always retained its force and expansion. Thus we not unfrequently have the combination of a pulse at 70, 80 or 90, or in general terms, under 100, while the thermometer in the axilla shows a persistent temperature above 100 degrees Fah.

"The following combinations of pulse rate and temperature were observed in the course of my investigations into the Lisbon epidemic; they are selected to show the absence of harmony and the frequent contrasts presented by the two sets of phenomena:

TABLE OF PULSE RATE AND TEMPERATURE.  
(Thermometer in axilla.)

Case.	Pulse.	Temperature.
1. . . . .	113 per minute.	102.0° Fah.
2. . . . .	100 "	100.0 "
3. . . . .	112 full.	104.0 "
4. . . . .	104 "	103.0 "
5. . . . .	92 "	101.0 "
6. . . . .	100 "	103.5 "
7. . . . .	104 "	103.0 "
8. . . . .	100 "	104.5 "
9. . . . .	84 "	99.0 "
10. . . . .	70 "	100.5 "

"From this table it will be seen that the highest pulse rate and the highest temperature did not correspond. On the contrary, the highest pulse at 113 had only a moderate degree of elevation of the thermometer, 102 degrees, while the pulse at 100 gave the highest temperature, and the lowest pulse rate, that at 70 beats per minute, was attended by coloration and an elevation of the thermometer to 100.5 degrees. There was, therefore, no constant uniformity of relation between the two sets of phenomena (pp. 270, 271).

**Hemorrhagic Form:**—I can testify to the statement, that in this form the yellow coloration constantly appears during the primary pyrexial state and while it is at its height, with the pulse over 100, and the thermometer in the axilla registering 101 degrees, 102 degrees, or even 104 degrees, the thermometer indicates generally a less considerable elevation of temperature in the hemorrhagic than in the sthenic cases. I have observed the pulse at 92 degrees and the thermometer at 101 degrees Fah. in a most characteristic well-marked hemorrhagic case. The pulse subsequently rose to 100, and 104 degrees in the same case, with elevations of the thermometer to 103.5 degrees and 103 degrees respectively, coloration of the skin being present to a marked extent. I do not, however, think that the temperature is generally so high in this class of cases. I believe that as a general rule the temperature in the hemorrhagic cases is from 2 degrees Fah. under that in the sthenic form. The transition from the sthenic to the hemorrhagic form is sometimes marked by a diminution in the rate and volume of the pulse, and a lowering of the thermometer; the patient's strength sinks rapidly at the same time, and in some cases a clammy sweat bedews the face for one or two days. This state of things is followed by, as it were, an explosive and universal lesion in the vascular system, leading to profuse hemorrhages at all available points of the cutaneous and mucous surfaces (pp. 274, 275).

"State of the Pulse:—I have nothing to record of a characteristic or peculiar kind in reference to the pulse. It is commonly less frequent than in the sthenic form, but has perhaps more of fullness and expansion, while its force is less. I have carefully noted the condition of the pulse in numerous cases, and in no one instance have I met with anything approaching to the dicrotous character either before or during the height of the hemorrhagic invasion; and that it was a very rare condition in the Lisbon epidemic is evidenced by the circumstance that in the large experience of Dr. M. Figueira, and of the physicians to the Desturo Hospital, it was presented but once; this observer could call to mind but one single case in which the pulse presented a well-marked dicrotous beat.

"The rate of the pulse is variable; it is commonly over rather than under, 100 per minute. It is most generally full, soft and responsive, and wanting in force and rebound. These, it will be observed are not very positive characters; but in such were presented in the great majority of cases observed by me.

"The pyrexial state is evidenced more decidedly by the state of the thermometer, which is usually over 100 degrees Fah. There is much variety in this respect; but what is important, and what can be positively stated, is that the hemorrhages occur during the pyrexial period, and with elevation of the pulse, and the thermometer above the standard. Thus we have seen them presented with characteristic force and intensity, while the pulse was at 100, and the thermometer in the axilla stood at 103.5 degrees; but this latter is unquestionably an exceptional elevation for the form of the disease now under consideration (pp. 376-377)."

My own investigations on the variations of temperature in different animals and in man under the action of various poisons and conditions of health and disease, and of climate, starvation and repletion, were begun in 1854, and have been continued without interruption up to the present time. The opportunities of recording observations on the pulse, respiration and temperature in various diseases were greatly enlarged during the recent Civil War (1861-1865). In 1870, a special monograph relating to yellow fever was transmitted to the AMERICAN MEDICAL ASSOCIATION, and in 1873 I endeavored to excite various observers in those cities in which yellow fever was prevailing, as in New Orleans, Memphis, Shreveport and Pensacola, to record critical observations on the changes of the pulse, respiration and temperature of the disease. The results of the portion of these labors which relate more especially to yellow fever will be found in the present chapter.

The temperature according to Schmidlein,<sup>38</sup> is highest in the first few days of yellow fever, and very often reaches a height of from 40 to 41 degrees C., (104 to 105.8 degrees F.) Very frequently with slight evening exacerbations. From the fourth to the fifth day the temperature slowly falls, and sinks down to normal or even below this. In cases which end fatally, it rises again toward the end, some 2 degrees C. (3.6 degrees F.) or even more.

According to Dr. William N. Nixon,<sup>39</sup> during the recent fatal epidemic of yellow fever in Buenos Ayres, 1870-1871, a high range of temperature was rapidly attained, and maintained with the exception of dif-

ferences of portions of a degree between the night and morning temperature, the night returns being slightly higher than those of the preceding morning; the decline was quite gradual.

I have refrained from citing the general observations of numerous writers, as Rush, Louis and a host of others, as to the presence of heat of surface in yellow fever, for they possess but little value for purposes of critical diagnosis, and confer little or no power of distinguishing between this disease and several other forms of malarial fever. We have sought rather to record the actual observations with the thermometer. A similar course will be pursued with reference to the changes of the pulse in this disease.

The fullest and most reliable observations upon the pulse in yellow fever, with which we are acquainted, are those given by Daniel Blair, in his account of the last yellow fever epidemic of British Guiana, 3d edition, London, 1852. According to this accurate observer: "The pulse was rarely very quick during any period of the disease. It was highest in the first stage, and gradually declined in frequency. Before death it generally became quicker and smaller, and when much fluid ejection occurred, it became extinct at wrist many hours before death. During convalescence the pulse was uniformly slow when no complication existed. The pulse was quickest in the cerebral variety. In some cases when the disease determined to the intestines, the pulse became startlingly slow, even on the second day of the disease; thus in Mr. Mackae's case it was 48; he recovered. In Case 2,895 of Seaman's Hospital, the pulse on the sixth day of fever was 24. The insidious nature of some of the attacks (when the seat of the malady was the intestinal, urinary or pulmonary apparatus) the perfect care of the patient, the external air of good health, and the solemnity of the pulse in such cases, frequently inspired the practitioner with a kind of awe and horror of the new, treacherous and remorseless malady.

In some cases of yellow fever, it seemed as if the poison acted directly, and at once, as a sedative on the heart; and in some cases there seemed a sudden and temporary excitability of it, which must have been favorable to the production of fatal local congestions.

TABLE SHOWING THE AVERAGE PULSE ON DIFFERENT DAYS OF THE DISEASE WITH THE NUMBER OF OBSERVATIONS FROM WHICH EACH AVERAGE IS OBTAINED.

No. of Observations.	Day of Disease.	Average Pulse.
121	1	97.10
338	2	90.80
406	3	83.53
388	4	80.44
311	5	78.56
206	6	78.74
125	7	78.78
71	8	75.62
46	9	75.76
29	10	77.58
16	11	76.37
7	12	76.00
5	13	79.20

Remarkable differences in the pulse are sometimes observed at different periods of the day.

1. Examples of rising in frequency:

Case 5,211. Morning, pulse 84; afternoon, pulse 126.

Case 828. Morning, pulse 80; afternoon, pulse 108.

Case 1,318. Morning of fifth day, pulse 70; afternoon, pulse 100.

Case 986. Morning of third day, pulse 72; afternoon, pulse 120.

Case 1,506. Morning of third day, pulse 52; afternoon pulse 86.

<sup>38</sup>On the Temperature in Diseases, by Dr. C. A. Wunderlich, p. 405.

<sup>39</sup>London Medical Times and Gazetteer. 1871.

Case 2,053. Morning, pulse 100; afternoon of fourth day, pulse 150.

Case 2,215. Morning, pulse 112; afternoon of fourth day, pulse 156.

Case 2,215. Morning, pulse 92; afternoon of eighth day, pulse 134.

#### 2. Examples of falling in frequency:

Case 583. Morning, pulse 108; afternoon, pulse 54.

Case 985. Morning, pulse 100; afternoon, pulse 72.

Case 986. Morning of second day, pulse 120; afternoon, pulse 108.

Case 1,137. Morning, pulse 96; afternoon, pulse 64.

Case 1,277. Morning of second day, pulse 100; afternoon, pulse 64.

Case 1,278. Morning of fifth day, pulse 120; afternoon, pulse 80.

#### 3. Examples of the falling and rising suddenly:

Case 986. On second day falls from 120 to 108. On third day rises to 120 and again falls to 80.

Case 1,318. On fifth day rises from 70 to 100; falls to 80 on morning of sixth, and to 50 in evening.

Case 2,215. On fourth day rises from 112 to 156, and on eighth from 92 to 134.

The pulse is often observed to rise or fall suddenly in frequency shortly before death.

#### 1. Examples of its rising:

Case 381. On day of death, rises from 68 to 80.

Case 656. On day of death, rises from 58 to 72.

Case 2,080. On day of death, rises from 88 to 120.

Case 2,601. From 80 day before death to 110 on day of death.

Case 2,609. On day of death rises from 78 to 100.

Case 2,680. On day of death rises from 84 to 120.

Case 2,712. From 80 day before death to 124.

Case 2,775. From 100 day before death to 134. From 80 to 96 and 116 on day of death.

#### 2. Examples of its falling:

Case 367. From 130 to 98 day before death, and again rises to 120.

Case 656. From 84 to 54.

Comparison of adult pulses in convalescence from virulent yellow fever with adult pulses in cases convalescent from inflammatory diseases where no febrile action had existed. Made in Seaman's Hospital Sept. 10, 1843.

#### YELLOW FEVER.

Name.	Pulse.	
Fletcher. . . . .	50	Irregular
McLaren. . . . .	56	Regular
Wilson. . . . .	52	Regular
McTammany. . . . .	58	Irregular
Allen. . . . .	58	Regular
Total,	274	
Average pulse	54.4	

#### INFLAMMATORY CASES.

Name.	Pulse.	Previous Diseases.
Pease. . . . .	115	Bronchitis, emphysema
Harding. . . . .	102	Paracentitis
Hall. . . . .	102	Asthma, empyema
Power. . . . .	90	Paracentitis, cough
Tynas. . . . .	100	Suspected tubercular infiltration in right lung
Total,	509	
Average pulse	101.8	

#### ACCIDENTS AND AILMENTS WITHOUT FEVER.

Name.	Pulse.	Previous Ailments.
Purcell. . . . .	76	Muscular pain
Sinclair. . . . .	84	Eccentricity of conduct
Martin. . . . .	84	Paralysis
Bilan. . . . .	84	Ankylosis of knee joint
Johuson. . . . .	84	
Total,	412	
Average pulse	82.4	

NOTE.—It is to be observed that these remarkable differences in the frequency of the pulse are rarely accompanied by corresponding febrile exacerbations. Although the remarkable slowness of the pulse in convalescence from yellow fever was early observed, the following limited trial for comparison by me on the subject is believed the only one which has been made. The fact was observed before the experiment was instituted.

Dr. Davy remarks upon these observations in his notes to the work of Dr. Blair: "Slowness of pulse in connection with certain diseases of the abdominal viscera—not of an inflammatory kind, is worthy of remark. Jaundice is a striking instance of this kind; less marked ones are met with in cases of functional derangement of the primæ viæ, though not without exceptions." . . . "Unusual slowness of pulse was often observed in the yellow fever of Barbadoes, and commonly accompanied with undue coolness of skin, especially in the extremities; it was a remarkable feature of the disease after its first invasion,—the time varying in different cases. The author's private observations on this symptom appear to me to be very valuable (pp. 74-77). Recent observations in New Orleans have confirmed the accuracy of Dr. Blair's statement with reference to the slowness of the pulse in yellow fever—as will be seen by an examination of the following table—which includes the labor of several observers working wholly independent of each other.

Dr. Porcher of Charleston, Dr. Charles Faget,<sup>40</sup> Dr. Just Finaste, Thomas Layton,<sup>41</sup> Prof. Samuel Logan,<sup>42</sup> Dr. Miner,<sup>43</sup> of New Orleans, Drs. Saunders<sup>44</sup> and Mitchell<sup>45</sup> of Memphis, have recorded valuable observations on the changes of the temperature, pulse and respiration in yellow fever.

Dr. Charles Faget,<sup>46</sup> of New Orleans, who is well known to the profession in this country and in Europe, for the accuracy of his observations upon disease and for the depth and extent of his learning, has produced one of the most striking and valuable articles on the relations of the temperature and pulse in yellow fever.

Dr. Faget bases his conclusions on thirty-eight tables of cases, recorded during the yellow fever epidemic of 1870 in New Orleans, furnished as follows: Sixteen by Dr. Touatre, Physician to the French Asylum; some from the asylum, the rest from the city; seven by Professor Bemiss, all from the Charity Hospital, thermometer in the axilla; three by Dr. Layton, and twelve by himself; the last fifteen from the very focus of the disease. Drs. Layton, Touatre and Faget took the temperature in the patient's mouth, placing the thermometer between the gums and cheek. The main object of this article as announced by its author "is to prove that yellow fever is a fever of a *continuous* type, and that it takes its place as a *specific* fever, distinct from all other forms, and is especially to be distinguished from the *malarial species*."

Dr. Faget thus places himself in accord with a host of writers on yellow fever, from the time of Lining, of Charlestown, S. C., in 1754, to the present moment, including the names of Bally, Louis, Blair, Bennet

## THE DISEASE OF INEBRIETY.

ITS STUDY FROM THE STANDPOINT OF THE EXPERIENCE  
OF AMERICAN PHYSICIANS OF EMINENCE WHO HAVE  
WORKED IN THIS FIELD OF RESEARCH.

BY EDWARD C. MANN, M.D.

NEW YORK CITY.

(Continued from page 21.)

ALCOHOLIC IDIOSYNCRASY.

Another class possesses an organization which may be termed an alcoholic idiosyncrasy; with them the latent desire for stimulants, if indulged, soon leads to habits of intemperance and eventually to a morbid appetite, which has all the characteristics of a diseased condition of the system, which the patient, unassisted, is powerless to relieve—since the weakness of will that led to the disease obstructs its removal. It might be well to divide inebriates into two other classes; the constant or daily, and the periodical drinkers. Of these two classes the constant drinkers are the most susceptible of treatment and cure. We find by a reference to the annual reports of the New York State Inebriate Asylum for the years, 1870, 1871 and 1872 the whole number of patients admitted during that time was 713. Of this number 402 were constant, and 311 periodical drinkers. Out of the whole number the hereditary taint, immediate or remote, existed in 347 cases, being nearly 50 per cent. As the two diseases, inebriety and insanity are closely connected in both their manifestations and results, nearly the same remedies, restraint and discipline are applicable to both conditions. Although inebriety is temporary insanity, those suffering from mania for drink should not be confined with the actually insane, for it would have an injurious effect, nor on medical and dietetic grounds is it advisable.

Prof. Austin Flint says: "Dipsomania is to be treated as a form of mental derangement." Dr. Joseph Parrish says: "Medical observations and diagnosis have determined that the diseased portion of the mind in cases of intemperance is the will, not the intellect. The inebriate knows, but is impotent to perform. For a better understanding of the requisite discipline demanded in the way of remedial restraint of inebriates, we notice some of the results of chronic inebriation, affecting more particularly the brain and nervous system—which in addition to the necessary medical treatment, necessitates strict discipline for the successful management of these cases. We have alcoholic epilepsy, alcoholic mania, delirium tremens, tremors, hallucinations, insomnia, vertigo, mental and muscular debility, impairment of vision, mental depression, paralysis, a partial or total loss of self-respect and a departure of the power of self-control."

We are warranted in repeating, even with more emphasis, the principles formulated by this Association (the American Association for the Study and Cure of Inebriety) at their first meeting in 1870, substantially as follows:

1. Intemperance is a disease.

2. Its primary cause is a constitutional susceptibility to the alcoholic impression.

3. The constitutional tendency may be inherited or acquired.

4. It is curable in the same sense that other diseases are.

It is now well established that inebriety is a formidable disease that may be inherited or acquired; and a disease that is closely connected with insanity in its manifestations and results, and to a certain extent in the means to be used for its removal and cure.

### MEDICAL TREATMENT.

The peculiar medical treatment to be pursued must be left wholly in the hands of the officer in charge, who should be an experienced physician, especially adapted for the position. He should be well informed in all matters pertaining to the disease, the treatment of which should be based upon a correct pathologic condition of the poisoning effects of alcohol on the different tissues and organs of the body, with a proper knowledge of the peculiar method to be pursued in individual cases, as well as a thorough understanding of the general practice essential for the cure of all inebriates. The practice in some institutions of letting down patients by degrees in the use of stimulants is decidedly impolitic, unless the patient is in a much debilitated condition and likely to sink. The general rule should be, cut off at once and altogether the use of alcohol in every form—more can be done by diet and medicine than can be obtained by a compromise in the moderate use of stimulants for a limited period. It is a mistake to suppose that any special danger arises from stopping the accustomed stimulus. Alcohol is a poison and we should discontinue its use at once as it can be done with safety and perfect impunity, except in very rare cases.

To secure all the benefits to be derived from medical treatment, we should have institutions for the reception of inebriates where total abstinence can be rigidly, but judiciously enforced for a sufficient length of time to test the curative powers of absolute restraint from all intoxicating drinks. When the craving for stimulants is irresistible, it is useless to make an attempt to reclaim and cure the drunkard unless the detention is compulsory, and there is complete restraint from all spirituous or alcoholic stimulus.

Dr. Francis Edward Anstie says: "There is very little chance except forced abstinence, tonics, nutritive treatment and the regulation of the diet." Prof. Austin Flint in speaking of the treatment says: "The successful treatment is rarely practicable except by means of institutions, in which the patient is under the same restrictions as in insane asylums." The restraint imposed by the institution and the self-restraint accepted on the part of the patient, are remedial agents from the moment he enters, growing stronger and more effective day by day, until finally he finds total abstinence not only possible but permanent. The hygienic and sanitary measures consist in total abstinence from all alcoholic beverages; good nourishing diet; well ventilated rooms; pure bracing air; mental rest and proper bodily exercise. The patient should be required to be prompt at his attendance at meals, and to observe regular hours for rising and retiring and to obey with military regularity and promptness all requirements that may be

conducive to health, and the formation of new and better habits.

#### LENGTH OF TIME NECESSARY TO A CURE.

"The length of time necessary to cure inebriation is a very important consideration. A habit covering five, ten or fifteen years can not be expected to be permanently eradicated in a week or a month. The fact that the excessive use of stimulants for a long period of time has caused a radical change, physically, mentally and morally, is not only the strongest proof that its entire absence is necessary, but also that it requires a liberal allowance of time to effect a return to a normal condition. The length of time necessary to the cure of inebriation will depend upon the duration of the disease and the amount of organic lesion which exists. The shortest period of continuous restraint, as a general rule, should not be less than six months in the most hopeful cases; and extending from one to two years with the less hopeful and more especially for the class of periodical drinkers, and those with an hereditary tendency."

Dr. Geo. M. Beard in a paper entitled, "Are Inebriates Automaton?" said: "As an illustration of the involuntary life in disease, inebriety is one of the most interesting, as well as most difficult to comprehend. So long as a man is merely a drunkard, or a victim of the vice of drinking to excess, he has it in his power to reform if he has a good endowment of will and can keep out of temptation. But in the disease of inebriety the sufferer has little or no more volitional control over his drinking symptoms than has a sufferer from malaria, or from sick headache or from hay-fever. All the influence he can exert over himself in the way of reform must be *indirect*—through the avoidance of the exciting causes whatever they may be; and in order to do this, it is oftentimes necessary for him to have the aid of outside parties. When his environment is bad, when temptation is before him, he has, practically, no will in this special relation, but is as truly an automaton as a patient in the horrors of tic-douloureux or smallpox, subject to the varying influence of weather, of wind, of diet, of medication, of mental influence in every form; the inebriate is, indeed, not himself but somebody else. In perfect health, man is a bundle of reflex actions, with a very small margin of volitional life, but in a disease of the nervous system, like inebriety, this small margin of what we call volition is swept away, and the man is an automaton so long as he is in the face of environment that excites the morbid desire and has no other method of exhibiting his manhood than by changing his environment, which he is oftentimes powerless to do without external aid; for the very effect of the environment is to take away the power of changing it, which is the very thing desired. Periodical inebriates, in the interval of their attacks, often put themselves under the charge of some friend, or enter an asylum, or leave the vicinity of temptation and this infinitesimal fraction is all that is left of their volition."

Dr. T. D. Crothers in writing on the "Etiology of Inebriety," says: "In discussing the causes of inebriety, we start from the broadest theory of cerebral defect as manifest in perversions of the nutritive functions and enfeebled will-power. Facts and experience clearly indicate that inebriety, from whatever cause, is a disease or stage of disease, either primary or secondary, as well marked as fever and

chills in malaria, or anesthesia and immobility in paralysis. The craving for liquor and the morbid impulse to commit crime are the same; the act is repelling to the higher reason in both, but the perverted will-power and function assumes control, and maintains it through the weakened organism. The degenerative processes often remain dormant for a long time, then on the application of its peculiar stimuli suddenly spring into activity. The brain and physical system may give no evidence of defect or derangement, or if any, only momentary, and yet the malady be far advanced. In general terms, this disease is always dependent on the dynamic and physical changes in the molecular neurine of the nerve centers. It may arise from causes acting on the functional energy, or from general systemic conditions which may be exciting or predisposing. The exciting causes produce changes of structure or function which constitute disease, or awaken latent tendencies to it. The predisposing causes induce such a state of the system or some part of it as shall dispose to certain kinds of malady and weaken the power of resisting morbid agencies. Inebriety can always be referred back to some special condition, circumstance, event or alteration of structure or function which, although it may not be clearly understood, constitutes the starting point of the disorder.

"In an examination of a large number of confirmed inebriates at the Albany Penitentiary, this statement was confirmed in nearly every case. A study of the particular causes indicate three classes or groups:

"1. Inherited causes, direct or indirect, including the diathesis or cachexia.

"2. Such general causes as produce inebriety in common with other insanities.

"3. Conditions and circumstances which particularly favor the development of inebriety. The strumous diathesis and cachexia, a syphilitic diathesis and cachexia, an arthritic diathesis and cachexia all tend to produce inebriety.

"The second group, called general causes, are those which frequently produce inebriety in common with other insanities. Of these, mechanical injuries seem prominent, such as injuries or concussions of the brain and the spinal cord and consequent alterations of nutrition. Blows on the head are not infrequently followed by violent paroxysmal drunkenness; railroad accidents, where the concussion and surprise are sudden and overwhelming, causing intense reaction on the nervous system (producing insignificant physical lesions), often develop inebriety and mania. A chaplain in the late war, injured in the leg by a shell (unexpectedly) although but a simple flesh wound, was several months in the hospital before recovery. From this time he became an uncontrollable drunkard and eventually died. A prominent physician was precipitated from his carriage falling on the head, and received a flesh wound of a minor character. Very soon after, inebriety was developed and he ended his life a raving maniac in an asylum. This rule in many cases indicates that injuries of the brain, spinal cord or any part involving numerous nerve trunks may end in cerebral disturbance of which drunkenness is a very common stage of the lesion. The injury being small in comparison to the mental disturbance which follows.

"Peripheral irritation or reflex excitability has been noticed as a common cause in many cases. A

London physician describes two cases where tape-worms excited inebriety and mental hallucinations, which disappeared on their expulsion. Several instances are on record where the use of pessaries in prolapsus uteri, and the prolapsus alone, has been the cause of mental disturbances of which drunkenness was the most prominent symptom. The irritation from prolonged lactation, or in dysmenorrhea, amenorrhea, nymphomania and fundamental disturbances of the genital organs, are frequently the beginnings, and in many cases the active causes of the disease. Numerous cases of puerperal insanity, preceded or followed by inebriety, are recorded in the English obstetrical journals. Cases of drunkenness during pregnancy, ending at delivery, are not uncommon. A remarkable case was noted at the Dublin Lying-in-Hospital some years ago, of a woman who, during the period of lactation drank gin to excess. This craving for stimulus began when the child was born and continued until the death or weaning of the child, the former being the most common termination. When lactation ceased the desire died away. Another case of equal interest is reported in a Western journal. A soldier wounded at Pittsburg Landing, previously temperate, became a paroxysmal drunkard. A portion of the shaft of the femur was injured, and continued to exfoliate dead bone until 1873, when it was removed by an operation. From the healing of the wound his drunkenness disappeared, and he is now one of the most enthusiastic of temperance men.

"Previous diseases are also active causes. Cerebral epilepsy, with its disordered fancies, auras and impulses ending in apparent recovery, only to be followed in time by a repetition, closely simulating the impulsive drunkard. The connection between inebriety and epilepsy is far more intimate than we are aware.

"Dietetic diseases—indigestion, inflammation of the stomach and liver often leave a train of predisposing causes. Exhaustive intellectual and physical exertion, by breaking up healthy cerebral action develops insane longings. Over-stimulation of the brain ends in changes and perverted tastes for alcohol or narcotics of some kind. Scholars and those who use the mind to excess, and laborers who only exert the physical system, when exhausted from overwork, have unnatural longings for something to restore the lost balance of mind and body. A prominent Senator spent thirty hours continuously in the preparation and delivery of a speech, and became an inebriate from that time. The sudden loss of property, disappointment, trouble, unrequited affections, may so depress the vital powers and disturb the circulation that drunkenness or insanity or both will follow. Ambition to lead, where it becomes a dominant passion, filling up every moment of thought, lowers the nutritive functions and leads directly to perversion of taste. Religious activity where the mind overflows with sentiment and emotion, may react into violent gluttonness or inebriety. No class of men are so thoroughly dyspeptic as clergymen and lawyers; simply the reaction of the mind to restore the equilibrium broken up by exhaustive labor. In every community large numbers of this class are on the verge of inebriety; all they need is the exciting cause; the fertile field is prepared to receive it.

"The perpetuity of the race depends upon the education received from both school and parent. If the

child grows up surrounded with unnatural morbid influences, ignorant indulgences and worse school education its ruin is inevitable.

"Under the third group are included all those conditions and circumstances which seem to particularly favor the development of inebriety. Of these, age has a controlling influence. Inebriety occurs at a time when the brain has reached its period of fullest activity. The brain power of infancy and youth can not bear much irritation without peril, its circulation is more rapid and susceptible to sudden fluctuations which are intense in their influence. This is apparent in the cases of permanent injury which follow from fear, anger or sudden emotions that profoundly impress the organism. At this time of life, organic changes take place which have a correlative mental transformation, the active degree of enervation existing makes the entire body extremely susceptible to commotions, in both the organic and mental development. I believe that future observations will indicate that inebriety begins here, although its development may be delayed for years. Sex, social condition, the season, weather, barometrical changes, unhealthy mental, physical and social surroundings, continuous excitement, and dark, damp, low places of residence are all causes of inebriety. The temperature and conditions of surroundings are evidently active causes. High degrees of heat and cold may so far impair the nutrition of the nerves, or produce paresis of the vasomotor centers as to result in inebriety. Sunstroke, inflammations, congestions and similar disorders of the brain cells coming from extremes of heat and cold are often followed by drunkenness.

"The captain of a South American steamer informed me that the firemen and most of the men employed (for any length of time) in this service became drunkards; this he attributed to the extremes of climate, and the heat to which they were constantly exposed. Leaving New York in midwinter, within a few days they are in a tropical temperature, then back again from the literal summer of the equator to the frequent polar temperature of New York. Inquiry among the furnace-men of Albany and Troy indicates the same facts; men exposed to a high heat after a time (to a large extent), become inebriates.

"Mental diseases are found to be largely controlled by cosmical influences, such as electrical phenomena, lunar attractions, velocities and directions of winds, geological formations, elevation above the sea level, etc. A professional man of great intelligence who is an inebriate becomes restless, depressed, and has headache and irregularity of temper when the wind blows from the south, and a storm is impending, also before a thunder storm. If he can resist the craving for liquor until the storm is over he is safe, but if the moon be at a change and the storm is delayed, he loses all control and has a paroxysm of drinking.

"In this very general review of the numerous causes, we have only indicated some of the great landmarks, leaving the wide field of hill and valley untouched.

"A brief summary may be indicated as follows:

"1. Inebriety or dipsomania, as a mental and physical disease, always is preceded by some special condition, circumstance or event, or alteration of structure.

"2. As in other diseases, the causes are numerous

and complex, either acting alone or together, increasing or diminishing, depending upon conditions not well understood.

"3. Its hereditary character and diathesis present many positive indications, which forecast its progress, and render its study a practical necessity to every student of science.

"4. As a stage or symptom of other disease, or a sequence, its causes and progress may be more obscure, but they have certain definite beginnings and endings, which a more accurate study will reveal.

"5. As a disease of accident or coincident, and circumstances or surroundings, its history and growth may be anticipated at every stage, and its result prognosed with certainty.

"6. Inebriety affecting the nutritive functions first, and after that the mind or *vice versa*, offers the widest field for research, and its pathologic and therapeutic relations extend over the entire realm of social and mental science."

Dr. Lewis D. Mason says: "It is our duty, then, when patients are sent to us or are sent to an asylum, to investigate the exciting cause of their inebriety. If it is some painful disorder and the patient tells us that he uses alcohol to relieve his pain, our course is at once apparent; to cure his disease or find some substitute for the alcohol. If we can not remove the cause, or find some efficient substitute for the alcohol, the patient passes to the incurable class of inebriates, a class that needs medical care as much as the incurable insane, requiring the treatment and restraint which only an asylum can give, for their constant or irregular resort to stimulants places them among the irresponsible classes of society. So whether curable or incurable, these persons who demand our heartiest sympathy will certainly present themselves. How we shall be enabled to recognize the possible exciting cause of their inebriety and perhaps forecast their future, is the object of this paper to point out."

#### Medical Students in Attendance on the Sessions of 1894-95 in the United States and Canada.

[Compiled for the JOURNAL by F. W. Reilly, M.D.]

In order to preserve the sequence of the Reports on Medical Education in the United States, and Canada, inaugurated and for many years so usefully carried on, by the late Dr. John H. Rauch, and subsequently continued by his assistant and successor, Dr. F. W. Reilly, the following circular letter was addressed last fall to the Deans, Registrars or Secretaries of 117 medical colleges which conducted lecture courses in 1893.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
86 FIFTH AVENUE.

CHICAGO, ILL., Oct. 29, 1894.

*My Dear Doctor:*—The JOURNAL desires "to take an account of stock" of the medical students in attendance at the current sessions of American Medical Colleges, and, to this end, forwards you the inclosed form which, it is hoped, will require from you a minimum outlay of time and trouble in filling up.

If not convenient to give the figures for all of the five sessions, it is desired that the numbers for 1893-94 and 1894-95 at least be furnished.

It is not now foreseen that mention of individual Colleges will be necessary or useful in the compilation, but no names of Colleges will be so used without express consent.

Inclosed please find stamped envelope for return of filled-out blank.

Faithfully yours,

JOHN B. HAMILTON, M.D., EDITOR.

The "inclosed form" provided for the name of the college, the name, address and official title of the respondent, returns of the numbers of students in attendance, by grades, at the sessions of 1890-91 to 1894-95 inclusive and a statement of the views of the respondent as to the cause or causes of any unusual increase or any decrease in the attendance at the present session.

This request was addressed to the following named institutions:\*

- \*Medical College of Alabama (1859) Mobile, Ala.
- \*Medical Department, Arkansas Industrial University (1879) Little Rock, Ark.
- \*Cooper Medical College (1859) San Francisco, Cal.
- \*Medical Department, University of California (1863) San Francisco, Cal.
- \*College of Medicine, University of Southern California (1885) Los Angeles, Cal.
- \*Denver Medical College (1881) Denver, Col.
- \*Medical Department University of Colorado (1883) Denver, Col.
- \*Gross Medical College (1887) Denver, Col.
- \*Medical Department, Yale University (1810) New Haven, Conn.
- \*National Medical College (1821) Washington, D. C.
- \*Medical Department, University of Georgetown (1850) Washington, D. C.
- \*Medical Department, Howard University (1867) Washington, D. C.
- \*Medical College of Georgia (1828) Augusta, Ga.
- \*Atlanta Medical College (1854) Atlanta, Ga.
- \*Southern Medical College (1879) Atlanta, Ga.
- \*Rush Medical College (1842) Chicago, Ill.
- \*Northwestern University Medical School (1859) Chicago, Ill.
- \*Northwestern University Woman's Medical School (1870) Chicago, Ill.
- \*College of Physicians and Surgeons of Chicago (1882) Chicago, Ill.
- \*Medical College of Indiana (1878) Indianapolis, Ind.
- \*Central College of Physicians and Surgeons (1879) Indianapolis, Ind.
- \*Fort Wayne College of Medicine (1889) Fort Wayne, Ind.
- \*College of Physicians and Surgeons of Keokuk (1850) Keokuk, Iowa.
- \*Medical Department, State University of Iowa (1870) Iowa City, Iowa.
- \*Iowa College of Physicians and Surgeons (1882) Des Moines, Iowa.
- \*Keokuk Medical College (1890) Keokuk, Iowa.
- \*Council Bluffs Medical College (1893) Council Bluffs, Iowa.
- \*Kansas Medical College (1889) Topeka, Kan.
- \*University of Louisville, Medical Department (1837) Louisville, Ky.
- \*Kentucky School of Medicine (1850) Louisville, Ky.
- \*Louisville Medical College (1869) Louisville, Ky.
- \*Hospital College of Medicine (1873) Louisville, Ky.
- \*Medical Department, Tulane University of Louisiana (1834) New Orleans, La.
- \*Medical Department, New Orleans University (1889) New Orleans, La.
- \*Medical School of Maine at Bowdoin College (1820) Brunswick, Me.
- \*University of Maryland School of Medicine (1807) Baltimore, Md.
- \*College of Physicians and Surgeons of Baltimore (1872) Baltimore, Md.
- \*Baltimore Medical College (1881) Baltimore, Md.
- \*Woman's Medical College of Baltimore (1882) Baltimore, Md.
- \*Baltimore University School of Medicine (1884) Baltimore, Md.
- \*Johns Hopkins Medical College (1893) Baltimore, Md.
- \*Harvard University Medical School (1782) Boston, Mass.
- \*College of Physicians and Surgeons (1880) Boston, Mass.
- \*Tufts College Medical School (1893) Boston, Mass.
- \*Michigan University, Department of Medicine and Surgery (1850) Ann Arbor, Mich.
- \*Detroit College of Medicine (1885) Detroit, Mich.
- \*Michigan College of Medicine and Surgery, (1888) Detroit, Mich.

\*The colleges are here named in the alphabetical order of States and in the chronological order of dates of organization in each State group; the figures inclosed in parentheses indicate the year of organization.

\*College of Medicine and Surgery, University of Minnesota (1883) Minneapolis, Minn.  
 \*Minneapolis College of Physicians and Surgeons (1883) Minneapolis, Minn.  
 \*Missouri Medical College (1840) St. Louis, Mo.  
 \*St. Louis Medical College (1841) St. Louis, Mo.  
 Medical Department, University of the State of Missouri (1845) Columbia, Mo.  
 Kansas City Medical College (1869) Kansas City, Mo.  
 \*St. Louis College of Physicians and Surgeons (1869) St. Louis, Mo.  
 Northwestern Medical College of St. Joseph (1880) St. Joseph, Mo.  
 University Medical College of Kansas City (1881) Kansas City, Mo.  
 \*Ensworth Medical College and Hospital (1882) St. Joseph, Mo.  
 Beaumont Hospital Medical College (1886) St. Louis, Mo.  
 Marion-Sims Medical College (1890) St. Louis, Mo.  
 \*Barnes' Medical College (1891) St. Louis, Mo.  
 \*Woman's Medical College and Hospital Association (1891) St. Louis, Mo.  
 \*Omaha Medical College (1881) Omaha, Neb.  
 John A. Creighton Medical College (1892) Omaha, Neb.  
 \*Dartmouth Medical College (1797) Hanover, N. H.  
 \*College of Physicians and Surgeons of Columbia College in the City of New York (1807) New York City.  
 \*Albany Medical College (1838) Albany, N. Y.  
 University Medical College (1841) New York City.  
 \*Medical Department, University of Buffalo (1846) Buffalo, New York.  
 \*Long Island College Hospital (1861) Brooklyn, N. Y.  
 Bellevue Hospital Medical College (1861) New York City.  
 Woman's Medical College of the New York Infirmary (1865) New York City.  
 \*Syracuse University College of Medicine (1872) Syracuse, New York.  
 \*Medical Department of Niagara University (1883) Buffalo, New York.  
 Leonard Medical School (1882) Raleigh, N. C.  
 North Carolina Medical College (1893) Davidson, N. C.  
 Medical College of Ohio (1819) Cincinnati, Ohio.  
 \*Medical Department, Western Reserve University (1843) Cleveland, Ohio.  
 \*Starling Medical College (1847) Columbus, Ohio.  
 Cincinnati College of Medicine and Surgery (1849) Cincinnati, Ohio.  
 Miami Medical College (1852) Cincinnati, Ohio.  
 \*Medical Department, University of Wooster (1863) Cleveland, Ohio.  
 \*Toledo Medical College (1883) Toledo, Ohio.  
 Woman's Medical College of Cincinnati (1887) Cincinnati, Ohio.  
 Ohio Medical University (1890) Columbus, Ohio.  
 \*Presbyterian Hospital Woman's Medical College (1891) Cincinnati, Ohio.  
 \*Medical Department of Willamette University (1864) Portland, Oregon.  
 \*Medical Department, University of Oregon (1887) Portland, Oregon.  
 \*University of Pennsylvania Medical Department (1765) Philadelphia, Pa.  
 \*Jefferson Medical College (1826) Philadelphia, Pa.  
 Woman's Medical College of Pennsylvania (1850) Philadelphia, Pa.  
 Medico-Chirurgical College of Philadelphia (1881) Philadelphia, Pa.  
 \*Medical Department, University of Western Pennsylvania (1886) Pittsburgh, Pa.  
 \*Medical College of the State of South Carolina (1832) Charleston, South Carolina.  
 Medical Department of the University of Nashville and Vanderbilt (1850) Nashville, Tenn.  
 Nashville Medical College (1876) Nashville, Tenn.  
 Meharry Medical Department of Central Tennessee College (1876) Nashville, Tenn.  
 Memphis Hospital Medical College (1880) Memphis, Tenn.  
 \*Tennessee Medical College (1889) Knoxville, Tenn.  
 Chattanooga Medical College (1889) Chattanooga, Tenn.  
 Sewanee Medical College (1891) Sewanee, Tenn.  
 \*Medical Department, University of Texas (1891) Galveston, Texas.  
 Medical Department University of Vermont (1823) Burlington, Vt.  
 \*University of Virginia (1825) Charlottesville, Va.  
 \*Medical College of Virginia (1838) Richmond, Va.

University College of Medicine (1893) Richmond, Va.  
 Wisconsin College of Physicians and Surgeons (1893) Milwaukee, Wis.  
 McGill University Faculty of Medicine (1824) Montreal, Quebec.  
 \*University of Toronto Medical College (1843) Toronto, Ontario.  
 \*Faculty of Medicine Laval University (1843) Montreal, Quebec.  
 \*Trinity Medical College (1850) Toronto, Ontario.  
 Laval University at Quebec, Medical Department (1852) Quebec.  
 Royal College of Physicians and Surgeons (1854) Kingston, Ontario.  
 Halifax Medical College (1867) Halifax, N. S.  
 University of Bishop's College, Faculty of Medicine (1870) Montreal, Quebec.  
 Medical Department, Western University (1882) London, Ontario.  
 \*Ontario Medical College for Women (1883) Toronto, Ontario.  
 Women's Medical College of Kingston (1883) Kingston, Ontario.  
 Manitoba Medical College (1883) Winnipeg, Ma.

Within three weeks of the date of the first circular, forty-nine colleges had responded, and on November 19 another circular letter was addressed to the sixty-eight from which no returns had then been received. It seems proper to make this statement because most of the colleges which first replied did so before their classes were fully made up for the session and there is, consequently, a shortage in the total actual attendance; the forty-nine colleges which first responded are indicated in the above list by \*—this for the purpose of securing proper allowance for their incomplete returns.

The addition of three colleges which reported subsequent to the tabulation which formed the basis of the editorial on the "Increase of the Medical Student Class," in the JOURNAL of Dec. 29, 1894, somewhat reduces the estimated total attendance therein given. In 1892 the 101 colleges whose returns are above given reported a total attendance of 15,695 out of a grand total of 18,340—or 85.5 per cent. of the aggregate attendance at 117 colleges. For 1893 they report, as above, an attendance of 15,865, which is 85.5 per cent. of 18,500; for 1894 they report an attendance of 17,784, which is 85.5 per cent. of 20,800—the aggregate attendance of the sessions of 1894-95.

These figures show a very slight increase in the classes of 1893 over those of 1892—only 160, or a fraction less than 1 per cent.; while for the current sessions the increase is 12.4 per cent. over the sessions of 1893. This great gain in the student class seems to be at the expense of higher medical education; in 1893 there were 803 four-year students in attendance; this year there are only 781—a loss of 2.7 per cent.

The following figures furnish some interesting comparisons:

United Kingdom (Great Britain and Ireland), 8,696 total registered medical students between 1889 and 1893; for the year 1893, based on yearly accretions, 7,000; \* population, 37,000,000.

France, total number medical students inscribed on the books of the Paris Faculty of Medicine for 1894, 5,144; † population, 40,000,000.

Germany, total number medical students registered for 1894, 8,684; † population, 50,000,000.

United States and Canada, total number medical students in attendance sessions of 1894, 20,800; population, 70,000,000.

Proportions: In the United Kingdom, 1 medical student to 5,286 of population; in France, 1 to 7,776 of population; in Germany, 1 to 5,757 of population; in the United States and Canada, 1 to 3,365 of population.

From the replies received and authorized for publication the accompanying table has been compiled.

\* Correcting the statement of "an American contemporary"—that "England has but 552 medical students"—the British Medical Journal of Dec. 22, 1894, says: "In 1893 the number of freshmen in the medical schools of England, Scotland and Ireland was 1,742, and by adding up the entries of the last four years it is clear that at present there must be over seven thousand students in the medical schools of the United Kingdom." This is more than four times as many as estimated in the JOURNAL editorial based upon Sir Richard Quain's figures.

† Brouardel. † Ascherson.

TABLE SHOWING NUMBER OF STUDENTS IN ATTENDANCE AT ONE HUNDRED AND ONE COLLEGES IN THE UNITED STATES AND

CANADA: SESSIONS OF 1894-95, 1893-94, AND AVERAGE YEARLY ATTENDANCE OF PREVIOUS YEARS.

Anonymous Schools.	356	322	221	118	*1057	1057	910		16.1+

1 A number preceding a college title refers to a note or comment bearing the same number in the Notes and Comments column following this Table. \* Including 40 specials.

The foregoing table gives the following aggregates for the 101 reporting Colleges, including 7 not specified by name, but whose totals are given under the title "Anonymous Schools."

First year students. . . . .	6,198
Second year students. . . . .	5,248
Third year students. . . . .	3,998
Fourth year students. . . . .	781
Special and irregulars. . . . .	2,359

Aggregate attendance, 1894. . . . .	17,784
Aggregate attendance, 1893. . . . .	15,865
Aggregate average previous years. . . . .	14,559

Percentages of Increase:

1893 over average of previous years. . . . .	8.9
1894 over 1893. . . . .	12.4
1894 over average of previous years. . . . .	22.1

NOTES AND COMMENTS.

<sup>1</sup> Estimated; return made "first day of regular winter term; students not all in. Decrease in numbers since 1891-92 due to adoption of three years' compulsory course."

<sup>2</sup> "We have just adopted a four-year curriculum. In the first year of the table, seventy-five includes students of the first and second years of the four-year course, i.e., first year thirty-seven, second year thirty-eight; total, seventy-five. I may say in addition that these figures include from two to five physicians each year—as well as a number each year who do not 'stick,' but as the same occurs at other colleges I presume these figures will afford basis for comparison."

<sup>3</sup> "The decrease in our attendance can be directly traced to the unequal competition of a State school removing to Denver and taking any student who applies, at no cost to the student whatever. It also means that our standard has been maintained."

<sup>4</sup> "Four-years' course begins with the session of 1895-96. A large increase occurred in sessions of 1893-94, owing to second and third years being taught in Denver, instead of Boulder, giving good clinical advantages. The increase seems likely to continue."

<sup>5</sup> "You will note that there has uniformly been a larger number of students in the first year than in the second or third. This has been due to the fact that a very considerable number of students fail at the end of the first year, and therefore have to repeat their work. Our entrance requirements are placed at the high school grade in the subjects in which we require examinations, and these requirements are well enforced, yet we have this large percentage of failures of men who can not stand the work of our first year. I do not know whether this is the experience elsewhere, but certainly our matriculation requirements are higher than the average of the country, and the whole thing seems to me to be a strong argument for the necessity of a higher grade of matriculation. I have felt for some time that this increase in the matriculation requirement was more needed in this country than the increase of time of study; that is, that three years with well prepared students would be better for the profession than a larger number of students kept at their professional work for a year longer. This opinion, however, does not seem to be the one which has prevailed. We have delayed starting the four years' course, hoping that there would be a general increase in matriculation requirements first, and while we do not altogether give up the hope of increasing matriculation examinations, we are about to adopt the four years' course in conformity with the other schools of the better class. I wish you might have included in your examination, the question of the proportion of medical students who are college graduates, and whether this is increasing or diminishing."

<sup>6</sup> "In this list the third and fourth years are given together, as last year was the beginning of the four year system."

<sup>7</sup> "A large number of students who matriculated last year withdrew and went to schools with a three-year course. The four-year course was made obligatory last year. This probably reduced the number of matriculates this year."

<sup>8</sup> "Four years' course began with the session of 1892-93."

<sup>9</sup> "The scholastic year has just been changed to a three-year term, and this is the first year of such change."

<sup>10</sup> "Small attendance in our second course is attributed to the fact that those who attended with us in 1893-94 can graduate in ——— Medical College at end of this term, while we would require them to attend until end of 1895-96. Those seeking early graduation have thus left us. The large increase in our first-year course is due to the school having adopted a three-year graded course and having by hard work for fifteen years established a very good reputation for giving thorough instruction." Total attendance 1894-95 (82) includes "one fourth year." The college, however, is not a four-year school.

<sup>11</sup> "The reason of decrease is on account of the grade being raised and examination more difficult; also our course being four years instead of three."

<sup>12</sup> "There is a larger percentage of students who have attended literary colleges than in any former year."

<sup>13</sup> "Faculty reorganized in 1890-91, with resulting steady improvement in size of the class."

<sup>14</sup> "Our school two years ago adopted a four years' course of study."

<sup>15</sup> Total 409 includes "two fifth year, one eighth year and thirty-six" not graded at date of making report.

<sup>16</sup> Attendance 1893-94 includes three women; first year, 1894-95 includes eight women; second year 1894-95 includes two women. "Our medical school is now in its second year. A noteworthy fact is that all of the fifty-two persons admitted in the two years are graduates of a reputable college, holding baccalaureate degrees, and several of them have pursued graduate studies in the sciences after completing their college work. In addition to these undergraduates in medicine, a large number of physicians are attending special courses in the Johns Hopkins Hospital, given by University professors: 1893-94—65; 1894-95 (to November 21)—44."

<sup>17</sup> "The large senior classes in 1891 and 1892 were due to the fact that in 1890 we changed from a three to a four years' course. This change, which was announced some years beforehand, brought us large classes in 1888 and 1889, students realizing that if they entered later than 1889, they would have to spend four years here. The small senior class in 1893 is explained in the same way. It appears from the figures that we have fewer medical students than we had last year. This is not true. The number is about the same as it was this time last year. There are always students coming here in the fall, who are unprepared to enter the medical course and have to do some work in the literary department or in the high school before they can enter. Some of these will enter the medical department at the beginning of the second semester. They will not be able to graduate with those who entered this last October, but it will increase the number of students appearing on our register when it is published next spring."

<sup>18</sup> "This college was reorganized last year, so members for past years would not be of value for statistical purposes."

<sup>19</sup> Causes of increased attendance: "Faculty thoroughly reorganized and prominent teachers from numerous Western schools having been selected. Also refusal to admit inferior students—no candidate being accepted unless presenting diploma of college or high school. College has no entrance examinations; they are farces!"

<sup>20</sup> "There has been an increase, due to the fact that the school has offered unusual clinical advantages, which have attracted students, in spite of the business depression. This increase is so marked, as evidenced by the fact that more than one-third more actual attendants are present, so that the capacity of the college is strained to accommodate the students. Matriculation list is twenty-five higher than attendance."

<sup>21</sup> "There was a marked falling off last session. The chief cause was, I think, that no one could graduate on two terms and such sought other schools. One of these now finds that his two-term diploma will not register him and he proposes to take another course. Another cause was that some of them thought they could more certainly graduate in another school. The hard times was another cause."

<sup>22</sup> "We had forty-three students in attendance last session; this year thirty-one—decrease the result of the scarcity of money."

<sup>23</sup> "The present is the ninety-eighth annual course of lectures at this college, and the number of students is the largest in its history. Causes: A hospital has just been opened in town. Possibly the depression in general business may have some influence."

<sup>24</sup> "There is a decrease in the first year, due to the establishment of the four-years' course."

<sup>25</sup> Not complete; return made November 1.

<sup>26</sup> "The junior class of session of 1891 was the first under the graded system."

<sup>27</sup> "Our collegiate year does not close until June, 1895, and we always have a considerable number entering our reading term in March—these will bring our number for 1894-95 up to 280 or more. This is the largest class we have ever had, and is undoubtedly due to the clinical advantages we offer."

<sup>28</sup> "1890-91 was the last year of the two-years' system; 1891-92 was the first year of the obligatory three-years' system. The unusually large class of 1890-91 was due to the fact that many students intend to take advantage of the

two-years' system. In 1891-92 three courses of lectures were made obligatory. Students were required to pay for each course attended and the fees on lectures were raised from \$140 to \$150. *Unclassified* includes those who did not attend the full regular course." In the total 409 for 1894-95 are included 60 "unclassified," and in the total 407 for 1893-94 are included 85.

<sup>29</sup> "Our four-years' course began with the session of 1893-94 and there are consequently no fourth year students as yet." The total third year students (thirty-four) include eight who are in the third year of the four-years' course.

<sup>30</sup> "With the session of 1896-97 we will require a fourth year. It is now optional."

<sup>31</sup> The increase seems to affect all schools, more or less, and is probably due to prospective enforcement of the four-years' course next year.

<sup>32</sup> "Increased facilities for instruction over years gone by have increased our class from thirty-eight the past season to fifty for the present."

<sup>33</sup> "The increase is due largely to the reputation of the school among college-trained students and school teachers. Our school is conducted on the normal methods of teaching. The students are enthusiastic and spread the good news to their friends seeking a medical education."

<sup>34</sup> "Increasing good reputation of the school and perhaps because of lack of opportunities for employment on account of times has driven more persons than usual to professional study."

<sup>35</sup> "The total number in attendance this year (session of 1894-95) may be increased by about thirty when students at present under conditions are permitted to matriculate after their conditions are passed."

<sup>36</sup> "Partly due to the fact that we begin our compulsory four years' course next year. Any progressive movement like this increases the popularity of the school as it indicates a determination to take a higher stand among the medical colleges."

<sup>37</sup> "The recent reduction in the number of students was probably due to the lengthening of the course of study to four years and the advance in the standard of entrance requirements adopted by the college."

<sup>38</sup> "The great clinical advantages by reason of its proximity to a large general hospital, viz.: The Western Pennsylvania Hospital. This and the fact that we have adopted the three-years' graded course explains the increased attendance."

<sup>39</sup> "Our facilities for teaching are being yearly increased and an increasing number of students are in attendance."

<sup>40</sup> "We now have a four-years' course of study."

<sup>41</sup> "The decrease is owing to the stringency in money matters all over the country."

<sup>42</sup> Heretofore conducted as a spring and summer school, not graded. "The school has now withdrawn from the Southern Medical College Association and will teach annual terms of ten months, from first of March to latter part of December, and permit students to apply for graduation after attendance upon two such annual terms and three years of study."

<sup>43</sup> "We have no required third year, but some students do distribute their study over three years." Two annual sessions of nine continuous months each are required for graduation. "The increase of students is due to the establishment of the graded course."

<sup>44</sup> "We have ten State scholarships, given in consideration of the fact that we receive aid annually from the State. We have no other scholarship feature, as is so often found in other medical institutions, or our number of matriculates would have been greatly increased. We have no dental or pharmacal department connected with our school. It is proper to state that the number of students above for session 1894-95 is incomplete, as we expect a number more to come in soon."

<sup>45</sup> "During the last session the qualifications for degree were increased from four six months' sessions and two compulsory summer sessions of three months each, to four sessions of nine months each. The increase in students was unexpectedly large this year which we attribute chiefly to the increased clinical advantages afforded from the opening of the new Royal Victoria Hospital."

<sup>46</sup> "The increase during the present session is probably due: 1, to the fact that the enlargement of the building last summer, increasing it to double its former size, was well advertised throughout the Province; 2, the work of the college is becoming favorably known; 3, the proportion of young men entering the profession in this section of the country, as shown by increasing attendance, is rapidly (too much so, possibly,) on the increase; 4, it has become gener-

ally known that it is the intention of the college to lengthen the term. This has had the effect of bringing a few students in earlier than they would otherwise have come."

Replies were finally received from all but the following:

Medical College of Georgia.

Medical College of Indiana.

Fort Wayne College of Medicine.

University of Louisville, Medical Department.

Louisville Medical College.

University of Maryland School of Medicine.

Baltimore Medical College.

Northwestern Medical College of St. Joseph.

Beaumont Hospital Medical College.

Marion-Sims Medical College.

Cincinnati College of Medicine and Surgery.

Medical Department, University of Nashville and Vanderbilt.

Memphis Medical College.

Royal College of Physicians and Surgeons.

Medical Department, Western University.

Women's Medical College of Kingston.

Laval University at Quebec, Medical Department.

Seven other colleges—two in Ohio, and one each in Illinois, Louisiana, Tennessee, Virginia and Canada—failed to give consent to the use of their names and these are consequently omitted in the preceding table; the figures furnished by them are, however, used in the aggregates—entered as "Anonymous Schools."

NOTE.—The JOURNAL will be pleased to make additions to the foregoing from colleges that have not heretofore responded and any proper revisions of the statements as published.—ED.

## ASSOCIATION NEWS.

**The Journal is Now Copyrighted.**—At the last meeting of the Committee on Management of the Board of Trustees, President Garcelon presiding, a resolution was passed directing the editor hereafter to have the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION copyrighted each week. The Trustees directed that all journals should have full and complete permission to reprint any article appearing in the JOURNAL, or part thereof, provided due credit is given to this journal when the article or item is reproduced.—JOURNAL AMERICAN MEDICAL ASSOCIATION.

[Good work well done.]—*Southern Practitioner.*

## SOCIETY NEWS.

**Marion County (Ohio) Medical Society.**—At the annual meeting of the Marion County Medical Society held in Marion, the following officers were elected for the ensuing year: Dana O. Webb, President; D. S. Maddox, Vice-President; A. M. Crane, Secretary; H. L. Uhler, Treasurer; O. W. Weeks, W. C. Denman and F. W. Thomas, Standing Committee. A new constitution and by-laws were adopted and signed by the members. The report of the committee on the revision of the fee-bill was made the special order of business at the next regular meeting in February, at which time the newly elected President will deliver his inaugural address.

**Lancaster (Pa.) City and County Medical Society.**—The regular monthly meeting of the Lancaster City and County Medical Society was held January 2. The attendance was large. The election of officers, which was the most important business of the meeting, resulted as follows: President, T. J. Wentz, New Providence; Vice-Presidents, J. A. E. Reed and J. F. Trexler; Recording Secretary, William Blackwood; Corresponding Secretary, Walter Boardman; Treasurer, G. R. Rohrer; Censors, A. M. Miller, Bird-in Hand, William Compton and M. L. Davis.

PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, JANUARY 12, 1895.

THE BOOK REVIEW BUSINESS.

"As good almost kill a man as kill a good book; who kills a man kills a reasonable creature, God's image; but he who destroys a good book kills reason itself."—MILTON'S *Areopagitica*.

It is with genuine regret that we invite the attention of the American medical profession to an abuse which has arisen in the matter of reviewing books by some otherwise excellent medical journals. For some years we have been watching the review columns of certain of our contemporaries to see if they showed the secret influence of the publisher. Facts which have come to our ears in the past year or two prove the suspicion to be more or less well founded that in reviewing or in *not* reviewing the publications of rival houses, the publisher's financial interest is frequently more plainly manifest than the reviewer's scientific interest. In other words, the editor-reviewer instead of speaking solely from the standpoint of the scientific or literary critic, becomes the mouth-piece of the publisher, and his opinion is accordingly vitiated as a medical guide.

The guiding principle of a dignified medical journal is that the reviewer and editor shall tell his readers the truth about a book sent for review, as he himself thinks and believes. He does not assume infallibility, but simply gives his opinion. But when the publisher of the journal is also the publisher of a competing book, and by some invisible method makes the editor speak according to the dictates of mercantile rivalry, we then have the abuse of which we complain.

Far worse, however, than misrepresentation of a book and manifest hypocrisy, is to ignore it altogether. Not to review the competing book of a rival firm

is worse than to review it through the counting-house spectacles. It is worse because it is mean, and because it is not likely to escape attention except by the rival publisher or author. Such a height has this editorial subserviency and publisher's dictation attained, that publishing houses often do not send certain new books to certain journals, because they fear that they can not get a fair review, or because they can get no review whatsoever.

The moral of the whole matter is the discreditable-ness of editorial subserviency, and the wrongfulness of the publisher in using for commercial purposes the columns of a journal supposed to be devoted solely to medical and scientific matters. There are, to be sure, all grades or degrees of this subserviency from that of the man who copies the eulogistic printed notices sent in advance by the publishers of the vilest trash, up to that of the "Olympian" editor smothered in respectability, and who, obedient to the wink of the publication office, damns with very faint praise or entirely ignores a great book, the merest mention of which might lessen the sales of a rival volume. And still another and important moral should not be omitted—the duty of the medical profession to own and govern the conduct of its journals. It is only in journals of the profession, for the profession and by the profession, that physicians will always be certain to find "the truth, the whole truth and nothing but the truth." In its review department, for instance, the readers of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION may rest assured that no secret influence governs the criticisms given of current literature. We have no interest in misrepresentation, in exaggerated fault finding, or in exaggerated praise, and more than all we have no interest in silently ignoring good books sent us for review. The progress of medical science depends largely on the dissemination of the best books, and the recommendation or criticism of books by medical journals should be carried on conscientiously and in the interest of medicine and not of the publication office. In fact it was for this reason, as much as for any other, that the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION was founded.

THE MAYBRICK CASE.

This celebrated case continues to attract attention in this country and in England. There is a well founded belief that Mrs. MAYBRICK is innocent, but thus far public sentiment has not been strong enough to move the Home Secretary to grant a pardon to this most unfortunate woman.

Perhaps there has never been a more flagrant example of jury incompetency than was shown in this trial. Of late there has been an increasing distrust in juries, and we would by no means join in a sweeping condemnation of jury trials, but believe

that surrounded by proper safeguards it has an abiding place in our jurisprudence. It is, however, in cases of involved circumstantial evidence such as the MAYBRICK case, that the ordinary jury fails. The average jury is able to judge of the credibility of witnesses and the general trend of testimony, but when it comes to weighing a complicated set of circumstances, the highly trained and educated mind can alone deal successfully with them. The jury which tried MRS. MAYBRICK, if we are to believe the statements concerning it, was rather below average intelligence. The judge who presided and is supposed to guide the jury in just such difficult cases was shown to have been suffering from parietic dementia at the time of the trial. He made a most intemperate charge which bore strongly against the prisoner and belittled every circumstance that pointed towards her innocence.

The chief points relied on by the Crown in this case were that MRS. MAYBRICK purchased arsenical fly paper, and shortly after her husband was taken with a severe gastro-intestinal inflammation. Arsenic was found in a medicine bottle and in some luncheon put up by her for her husband. Supplies of arsenic were found in places about the house to which the prisoner had access. The accused had been unfaithful to her husband who had beaten her and she had written to her lover stating that MR. MAYBRICK was dangerously ill. Arsenic was found in a bottle of glycerin which she gave the nurse to cleanse MR. MAYBRICK'S mouth. There were arsenical stains on her dressing gown. Her husband said: "Don't give me the wrong medicine again," and "Oh, Bunny, how could you do it? I did not think this of you."

On behalf of the prisoner it was shown that she had used arsenical fly papers in making a face wash. The purchase was openly made and she bought other ingredients at the same time. Her husband had been ailing for a long time with a severe gastro-intestinal disorder. He was a confirmed arsenic eater, and used to take it in his food at luncheon. The arsenic found about the house could not have been derived from the fly paper, and the purchase of the latter showed that she was not aware that arsenic was in the house, and since the trial this arsenic has been traced to the husband. The prisoner summoned the physicians and the nurse. The letter to the lover contained other exaggerations than that regarding the illness of her husband and was written for the purpose of inducing him to remain in the country. After their quarrel, husband and wife had become reconciled, and the illness began a month later. Arsenic in quantity as large as that found in the mouth wash is a common impurity in glycerin. The spots on the dressing gown are easily accounted for by the use of the face wash. The husband never referred in any way to poison or arsenic, though he

knew there was a supply in the house, and felt certain that his wife was unfaithful to him. The change for the worse in MR. MAYBRICK took place the day he forgot to take the luncheon which his wife had prepared, and in no case did it appear that the illness was aggravated soon after anything administered by the accused. The amount of arsenic found *post-mortem* was far less than a fatal dose and was consistent with its medicinal administration. This opinion was given by the late CHARLES MEYMAT TIDY, an authority in legal medicine and one of the best toxicologists in England.

It may be that MRS. MAYBRICK is guilty of the murder of her husband, but if so there is a deplorable lack of evidence of the fact. As for the ordinary legal rule, that reasonable doubt shall acquit, it becomes an utter absurdity when applied to such evidence as was adduced in her case.

#### THE MEDICAL COLLEGES OF THE UNITED STATES.

Some weeks ago the JOURNAL sent out a circular to all the Medical Colleges in the United States and Canada, and the returns which are now all in, were handed to DR. FRANK W. REILLY, well known as an authority on the subject of medical education, for tabulation and summary. The results are this week spread before our readers, and will doubtless surprise many whose knowledge on the subject is not based on intimate acquaintance with the schools themselves. The advance that has been made in the last decade is not so apparent as to be very gratifying to the friends of higher medical education generally, or to the medical profession. The report may well serve as a convenient basis for comparison, in the year 1905, and the JOURNAL of that year, we trust may be able to show a progress equally marked.

#### SELECTIONS.

**A Department of Public Health.**—The country is to be congratulated upon the fact that the President's message to Congress recommends a Public Health Department. Through the whole message, there is no more important subject considered than this one. Indeed, for the benefit of the people at large it outweighs in importance all other subjects considered in his message. The people may differ as to free iron and coal, and as to the repeal of the differential duty on sugar; it may be doubted, too, whether the Army should be increased in numbers or not, and some might doubt the propriety of extending the coast defenses, but if the health of the nation is to be preserved, no one can doubt that a Department of Public Health should be established. The following is the pointed way in which the President states his opinion on this matter:

"I am entirely convinced that we ought not to be longer without a National Board of Health or National Health Officer charged with no other duties than such as pertain to the protection of our country from the invasion of pestilence and disease. This would involve the establishment, by such board or officer, of proper quarantine precautions or the necessary aid and counsel to local authorities on the

subject, prompt advice and assistance to local boards of health or health officers in the suppression of contagious diseases, and, in cases where there are no such local boards or officers, the immediate direction by the National Board or Officer, of measures of suppression, constant and authentic information concerning the health of foreign countries and all parts of our own country as related to contagious diseases, and consideration of regulations to be enforced in foreign ports to prevent the introduction of contagion into our cities and the measures which should be adopted to secure their enforcement.

"There seems to be at this time a decided inclination to discuss measures of protection against contagious diseases in international conference, with a view of adopting means of mutual assistance. The creation of such a National Health establishment would greatly aid our standing in such conferences and improve our opportunities to avail ourselves of their benefits. I earnestly recommend the inauguration of a National Board of Health or similar National instrumentality, believing the same to be a needed precaution against contagious disease and in the interest of the safety and health of our people."

The farming element of the country was clamorous for a long time that a Department of Agriculture should be established, and it was only within the last few years that recognition was accorded it. That it was a wise move the whole country now agrees. How much more important is it that a Public Health Department be established. When one reads in the daily press of the existence of great epidemics prevailing across the water, the danger is made very apparent and we call for assistance and protection from every hand. In times past, such scourges as cholera and yellow fever were left alone to devastate our country with no recognized power to stop their onward progress. With a Department of Public Health established, and a Secretary of the same in the Cabinet, the country would feel safe, in that a power existed that would enable us to grapple with such terrible monsters. It is well enough to look after the finances, and have an able Secretary of the Treasury; it is important that the Army should be looked after by the Secretary of War; that the Navy should be made a pride to the country, and its head should be, as it is, represented by a great mind. Each and all of these departments that have at their head honored and distinguished men deserve to be controlled with the greatest accuracy and precision. To this proposition no one would dissent, and yet, strange to say, the Congress of the United States in the past has hesitated to establish a Department of Public Health. To keep abreast of the times and to be equal to other nations, the time has now come when such action is imperative. We find other nations are continually appointing commissions for the investigations of contagious diseases. Their people must and shall be protected from all such. Money is expended freely and lavishly for the investigation of scientific medical problems, and the result is that thousands upon thousands of lives are saved annually. We do not want to fall behind others in this line of duty, but in every international conference of this kind the United States should be represented and backed by the strong hand of the Government. In the name, then, of science, of mercy, and of justice to the people at large, let a Public Health Department be established. The medical profession of America will unite as one man in thanking the President for his recommendation in this matter. Let every medical journal in the land publish and indorse his views. Quoting the able editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, we would say: "*Let there be created a Department of Public Health.*"—*Mathews' Medical Quarterly*,

**Must be Recognized.**—Medicine must be recognized in the Presidential Cabinet, and also in the official family of every governor and mayor of large municipalities.—*Cincinnati Lancet-Clinic*.

## CORRESPONDENCE.

### Medical Education and the Colleges.

Boston, Mass., Jan. 2, 1895.

*To the Editor:*—The numerous addresses, editorials and letters which have appeared recently, not only in your own valued JOURNAL, but in many others, show how much the medical profession is thinking and talking about its own condition and how anxious it is to set its own house in order. They have inspired me also, who have had something to do with the manufacture of doctors in more than one State, and who have had many opportunities to inspect the finished product, to make a few remarks on the same subject.

It is said that the medical profession in the United States is overcrowded. It can not be denied. The sick among 450 people do not need a whole doctor, and unless they include a liberal proportion of the 400 or their imitators, or unless very vigorously cultivated, do not support one. Hence the multiplication of specialties. But is it the only profession which is crowded? Ask any young man just out of college what he intends to study next, and see if he thinks there is any walk of life which he can enter without pushing. It is simply bearing a part in the general tendency of the times.

There are, however, certain causes for a special overcrowding of this profession, for a part of which it is itself to blame and another part which has its roots far deeper in the weaknesses of human nature. A young man generally chooses his profession more or less consciously, from one of three motives, or perhaps two of them combined: 1, the attractiveness of its study or practice to his intellectual and moral tastes; 2, the probability of its giving him a comfortable subsistence; or, 3, the possibility of its making him very rich or very famous. The first of these motives brings the best and a very large class of material to the medical profession. The men who choose the study of medicine for their love of science and who practice it because it brings them nearer to science and to humanity are the solid standbys of the profession, the steady line of brave and disciplined men without whom it would become an incoherent mob of self-seeking, vainglorious, boasting, turbulent quacks. Happily they are in the majority. Unfortunately it is not rare to meet those who have persuaded themselves that they have an overmastering love for science or for medicine merely because they have so intense a dislike for the other alternatives, which are apt to be some of the humbler walks of life in which they might, if they would, walk, less conspicuously indeed, but with much greater benefit to the community. I remember the surgeon in a military hospital showing me a case where the first surgeon had sewed up a scalp wound very neatly over a fracture of the cranium, with the remark that he had "spoiled a good tailor to make a poor surgeon."

This brings me to the second class, who choose medicine simply as a means to a comfortable livelihood and perhaps to an improvement in social position. Here, too, a normal and proper desire if backed by good sense and industry, send into the profession many, not usually its brightest ornaments, but excellent practitioners and highly useful men in the community.

The third class attack the profession and the public at its weakest point. The gambling instinct, the desire to "go a-fishing," to "take a flyer," to get something for little or nothing, or to play heavy stakes for great prizes is an exceedingly common if not universal one.

In many professions the candidate knows that if he is to have any chance of winning great prizes he must put in great stakes in talents and in industry. If he realizes that he has not the former he does not try to come into that game.

But in medicine he can not help seeing that, in this country at least, the most money does not go to the profoundest pathologist, the most acute diagnostician, or even the really best practitioner. He has constantly before him the example of men who have won fortune with a very moderate proportion of professional attainment, but an excellent capacity for displaying all that they know and a very great deal of shrewdness in concealing what they do not know. It is not strange, then, that a youth with a certain quality of brain and a certain appearance of brainpan should conclude that the medical profession is the best market to which he can carry it.

Add to these three classes the few who drift into medicine as they might have drifted into anything else, and whose chances of success may be as good there as anywhere, and we certainly have an overcrowded profession. The medical schools until recently encouraged them all. Some do so still. Overcrowding means treading on each other's toes, scrambling, pushing, more or less decorous, certainly not tending to the dignity of the profession, going far beyond the bounds of generous rivalry and approaching dangerously near the manners and morals of advertising trades.

For remedies we have to place before the entrances to the profession, sieves coarse and fine, at least an entrance examination for admission to the schools and a State examination or a rigid inspection by the government of degrees and methods; the one of which, by its actual presence, and the other by the fear of its approach, would keep out the least competent. The first I would demand not only because certain subjects, like chemistry, physics, and elementary biology ought to be preliminaries to a medical education but because the student ought to know how to study. He cannot afford to spend his precious first year, which ought to be given to profitable work in dissecting room and laboratory, in learning how to make use of his opportunities.

The State examination should not deprive any American citizen of his inalienable right to be humbugged. If he wants it he should have it, but under its own name. But since the rights of the man of common sense and those of the community in general deserve to be protected as much as those of the seeker after miracles, the State has a right to say that those who publicly profess to be physicians in the ordinary sense of the word should have some preparation therefor. The process of waiting for the survival of the fittest is too tedious and too disastrous.

Between these two comes medical education, which is rapidly getting into a very healthy shape. The general recognition of the paramount importance of laboratory instruction in all branches of physical science, in other words making the student work himself instead of merely watching the results attained by the professor's experienced hand, is one of the important changes which is going on more rapidly now than ever before. In medicine this means clinical work, and especially clinical work in small classes. The small hospitals so rapidly springing up all over the country are a most important means to this end, and both they and the older and larger ones should be made to give such instruction to the largest possible number of students. The number of internes and externes should be increased to the widest limits consistent with the proper working of the institution. Much good material now goes to waste for want of orderly record and careful sifting which might be done by the aid of students to their own great advantage as well as to that of science.

No one can look over a series of French and German inauguration theses or the voluntary papers of many of our own young men, without recognizing how immense is the value in mental training of taking up some special subject under the guidance of an instructor and following it care-

fully and thoroughly. Every hospital in this country, large and small, should be a center of education for the profession and for the laity.

Medical education is advancing in the right direction, and that rapidly, but the end is not yet. It is only four or five years since a friend told me that he had met (I think in a so-called "consultation") a recent graduate who confessed that he had never felt a patient's pulse. A medical school without abundant laboratory facilities I would, if it were in my power, remorselessly stamp out. One without adequate clinical opportunities not only offered but with their careful use rigidly enforced I would treat with as little respect, unless it were willing to recognize distinctly and formally its position merely as a feeder.

But until sentiment changes, the pressure upon our sieves will be strong and some bad material will get through. For this change we and our children and children's children, will have to wait. When the community can be made to see that a humble place well filled is more honorable than a conspicuous one badly filled; that no profession carries with it respect and dignity except to him who has worthily won it, then and not before will medicine like the other professions cease to be overcrowded. I am very truly yours.

E.

#### Civil Service in State Institutions.

CHICAGO, ILL., Jan. 8, 1895.

To the Editor:—The readers of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION will no doubt be interested to learn that an attempt will be made to introduce into our State institutions a system of civil service reform in the formation of the medical staff. The affixed circular letter was recently sent to the trustees of the four insane asylums. The matter will be thoroughly discussed at an approaching meeting of the superintendents of the insane hospitals and the President of the State Board of Charities. The competitive examination will be impartial and no doubt patterned after that at the Cook County Hospital.

Yours truly,

BOERNE BETTMAN.

STATE OF ILLINOIS, THE BOARD OF STATE COMMISSIONERS OF PUBLIC CHARITIES.

SPRINGFIELD, ILL., Dec. 20, 1894.

TO THE TRUSTEES OF THE ILLINOIS HOSPITALS FOR THE INSANE:

Gentlemen:—It is generally acknowledged by those who have had an opportunity to become familiar with the routine of our hospitals for the insane that the medical staff in all of them is numerically insufficient. In large institutions at least one medical attendant should be allotted to every 200 insane patients. In most of our hospitals a far greater number of insane are cared for by one physician.

The desire to better care for the insane and to stimulate scientific research induces us to recommend a system in use in most of the general hospitals of the world, viz.: The employment of internes. We suggest the appointment of one interne for every 400 patients cared for in each of the four insane asylums of the State. The appointments should be given to those who have obtained the highest mark in a competitive examination. The time of service of these internes is to be one year and a salary of \$20 per month besides board and lodging.

All senior students of medical colleges in good repute with the State Board of Health, and those general practitioners of this State who have not practiced more than five years, are eligible to the examination. Vacancies in the staff of the regular assistant physicians should be filled from the ranks of these internes. We suggest that all further rules and regulations governing the appointment and employment of these internes be definitely settled at a meeting of the superintendents of the four State Hospitals and the chairman of this Board, to be hereafter called.

We also desire to impress upon the administrative officers of the various hospitals, that a well qualified pathologist is needed at each institution. The pathologist will be expected to organize staff meetings and to deliver regular courses of lectures on mental diseases and their allied branches. To

this end a laboratory should be equipped at each hospital.  
By order of the Board.

BOERNE BETTMAN, M.D., President.  
GEO. F. MINER, Secretary.

Approved by the Governor.

### Jefferson Medical College.

*To the Editor:*—Many members of the Class of 1879 Jefferson Medical College, of Philadelphia, are desirous of having a class reunion on the occasion of the fifteenth anniversary of their graduation. Owing to changes, comparatively few addresses are known and therefore this means is resorted to, with the hope that every member of the Class of 1879 who reads this notice will communicate at once with their Class President, Dr. Philip R. Koons, Mechanicsburg, Cumberland County, Pa.

### NECROLOGY.

**DR. A. B. COOK.**—Dr. Archibald B. Cook, of Louisville, Ky., died on the 2d inst. His death was caused by pleuropneumonia, but he has been in ill health for some time, not giving up until the very last, in fact making his rounds one day with a temperature of 105 degrees. Dr. Cook was born in Nobletown, Pa., sixty-six years ago. His father, John Cook, was a native of County Derry, Ireland. He received a liberal education in Wheeling, W. Va., and at Jefferson College in Allegheny County, Pa., and was a prominent member of the Franklin Literary Society of that College. In 1845 he received the degree of A.B., and in 1851 the degree of A.M. was conferred upon him. He studied medicine and graduated from the Medical College at Sharpsburg, Pa., from the College of Physicians and Surgeons, New York, and from the Kentucky School of Medicine in this city, and began the practice of medicine in this city in 1855. He was a member of the AMERICAN MEDICAL ASSOCIATION, Kentucky State Medical Society, and was a vice-President of the College of Physicians and Surgeons, this city, now defunct. For years he was Professor of Surgery in the Kentucky School of Medicine, and for twenty years a surgeon of the Marine Hospital. He was a member of the local Board of Health and of the Board of Commissioners of Public Charities. On Feb. 12, 1872, Dr. Cook married Mrs. Fannie M. Roberts who died on Nov. 29, 1886. Six years ago he was again married, and his wife and one child survive him. In 1860 Dr. Cook was appointed on Gen. S. B. Buckner's staff with the rank of major.

**DR. F. L. HARROD.**—This bright and talented young physician was, so far as we can learn, shot down in cold blood at his home in Harrodsburg, Ky., and mortally wounded by Sheriff John T. Vanarsdell January 4. The shooting took place in front of Dr. Harrod's office. Vanarsdell approached and without any other words than an oath, fired at the Doctor, the bullet taking effect in his chest, and after he had fallen was shot again in the stomach. The wounded man expired without regaining consciousness. Dr. Harrod was 33 years of age and was a lineal descendant of the pioneer John Harrod, the founder of the town which bears his name. He was graduated from the Louisville Medical College in 1891, and began the practice of medicine in Harrodsburg. He was local pension examiner, and local observer of the Kentucky State Weather Service. The remains were buried in Lexington, Ky., with military honors, as the deceased was assistant surgeon to the Second Regiment, K. S. G.

**DR. ADAM HARTHILL.**—Dr. Adam Harthill, one of the leading veterinary surgeons of Louisville, died at his residence on the 30th ult., aged 39 years. He was born in England but came to this country when young and settled in Louisville soon after.

**JAMES F. RHODES, M.D.,** of Philadelphia, January 2.—**Wm. A. Elder, M.D.,** of Bloomington, Ill., January 3, aged 69.—**William Osgood, M.D.,** of North Yarmouth, Me., December 25, aged 69.—**Homer Campbell, M.D.,** of Racine, December 25, aged 69.—**John S. Robertson M.D.,** of Whiteville, Tenn., December 26, aged 75.—**A. S. Huston, M.D.,** of Anderson, Ind., December 28.—**G. W. Jones, M.D.,** formerly of Covington, Ind., at the Bermuda Islands, January 7, aged 50.

### PUBLIC HEALTH.

**Diphtheria Antitoxin.**—Surgeon-General Sternberg, U. S. A., has detailed Assistant Surgeon Charles B. Ewing to establish a diphtheria antitoxin "plant" at Jefferson Barracks, Mo., and Dr. Ewing has already procured a number of horses which after being subjected to the mallein and tuberculin tests and otherwise proved healthy, will be utilized for this purpose.

**New York's Lowest Death Rate.**—Calculated on an estimated population of 1,957,452 the death rate of New York city for 1894 was 21.05 per thousand—the lowest in the history of the city. There were 41,212 deaths during the year, of which 4,752 were from pneumonia, 4,687 from phthisis, 2,492 from Bright's disease, 2,371 from diphtheria, 2,177 from heart disease, 541 from scarlet fever and 156 from smallpox. Following are the death rates for the preceding six years:

1888 . . . . .	25.23	1891 . . . . .	24.73
1889 . . . . .	24.07	1892 . . . . .	24.26
1890 . . . . .	23.51	1893 . . . . .	23.52

**Epidemic Diseases.**—Influenza or "grip," which seems to have been lurking in the country since its epidemic prevalence in 1891-92, is assuming formidable proportions in New York and Brooklyn. In the former city 7 deaths were reported from the disease last week, with 3,000 cases under treatment. In Brooklyn, Dr. R. M. Wyckoff, Deputy Health Commissioner and Dr. Ezra M. Wilson, bacteriologist of the Board of Health, were reported suffering from severe attacks. The Board is having more than its share of sickness, Dr. L. C. Ager, sanitary inspector, and Dr. Jerome B. Thomas, assistant bacteriologist, also being disabled, the former with typhoid fever and the latter with diphtheria contracted in the laboratory.

Dr. Wingate, Secretary Wisconsin State Board of Health, reports, January 7, smallpox at Chippewa Falls, Manitowoc Rapids Tp., Mishicott and Milwaukee—sixty-eight cases in the latter city, twenty-seven in hospital and forty-one in homes. From another correspondent it is learned that the outbreak at Manitowoc Rapids is due to infected goods stolen from the smallpox hospital occupied at that place in the summer of 1894. Dr. Probst, Secretary of the Ohio State Board of Health, reports January 4, smallpox at Mansfield, Toledo and Millersport. Dr. Scott, Secretary Illinois State Board of Health, reports, January 7, an outbreak of smallpox at Kirkland, DeKalb County, which it is feared may be serious owing to the fact that the first case was treated as measles and an unknown number of persons exposed. The Detroit City Board of Health discovered January 4, that a carpenter, who had been employed on the new smallpox hospital, had contracted the disease and had been under treatment for ten days by a "Christian scientist;" the scientist has been arrested and will be prosecuted. On the 9th inst., there were eighty-six cases in the Chicago smallpox hospital; none in homes so far as known to the Health Department.

A cable dispatch of the 9th inst., confirms the reports of Dr. Cleary, Sanitary Inspector U. S. M. H. S., at Rio de Janeiro, as to the existence of Asiatic cholera in the Argentine Confederacy. The dispatch announces that it has been proclaimed epidemic in the provinces of Rosario and Santa Fe. Dr. Cleary had previously reported its extension along the line of the Sao Paulo Railway to a number of towns and railway stations in the Brazilian States of Sao Paulo and Rio de Janeiro, in consequence of which railway travel had been suspended and communication between the infected district and the port of Rio cut off. The comma bacillus of Koch had been discovered in most of the cases and the pretext of "choleraform diarrhea" had been abandoned; isola-

tion, disinfection and quarantine measures are rigidly enforced and it is hoped to prevent the infection of the port, although one case had appeared which Dr. Cleary believes to have been cholera.

## MISCELLANY.

**Medical Examiners in Georgia.**—We are informed that Georgia now has three Medical Examining Boards, one Regular, one "Homeopathic" and one "Eclectic."

**Personal.**—John L. White, M.D. of Bloomington, Ill., who was recently elected a member of the Legislature has resigned his position as a surgeon of the Chicago and Alton Railroad. He is an old and valued member of the AMERICAN MEDICAL ASSOCIATION.

**Medical College of Indiana.**—The Faculty of the Medical College of Indiana held a meeting December 14. It was decided to erect a new building at a cost of not less than \$50,000.

**New Health Officer.**—Governor Levi P. Morton, of New York, has recognized the general voice of the New York profession, by appointing Dr. Doty, of the City Board of Health, to be Health Officer of that port, *vice* Wm. T. Jenkins, M.D. No one could read the report of the New York Academy of Medicine on the conduct of quarantine in 1892, without realizing that the quarantine has, to say the least, been in very unsafe hands during the Jenkins regime.

**Cancer of the Breast, Operation Without Suture.**—M. Berrut reported a case of a woman in whom he made, twenty years ago, ablation of cancer of the breast. The wound was left open and healed by granulation. The cure was definite and has been maintained, until now when it was seen twenty years after the operation.—*Revue de Chirurgie*, November, 1894.

**Army Medical School.**—There are only two Assistant Surgeons in attendance at the current session of the Army Medical School as against seven in 1893-94. The Secretary of the Faculty, Walter Reed, Major and Surgeon, U. S. A. writes: "Decreased attendance at the session of 1894-95 is due to reduction of number of Assistant Surgeons, U. S. A., by recent act of Congress; otherwise our class would have numbered twelve. Our session only extends from November 1 to March 1 (four months) and is intended to give to recently appointed Assistant Surgeons careful instruction in bacteriology (especially the study of pathogenic organisms) in pathology of tumors, blood, urine, etc., and work in the chemic laboratory, embracing examinations of water, air, urine, adulteration of foods, etc."

**The Index Medicus.**—The following circular has been issued:

CHICAGO, Jan. 1, 1895.

*Dear Doctor:*—Since 1885 the Index Medicus has been carried on at a loss to the publisher, and without compensation to the editor, and within the last year the subscription list has so far diminished that the journal will cease to appear unless very substantial support is given by the profession.

The undersigned, committees of the Chicago Medical Society and Chicago Academy of Medicine, deplore the loss to American medicine that will accrue from the discontinuance of this valuable publication. It is the most complete bibliography of medicine that has ever been published, and the only one in the English language. The physicians of Chicago ought to feel a strong interest in maintaining this publication, as it is the only index to the vast accumulations that are added yearly to the Newberry Library. Will you not lend your support to the Index by sending a subscription to Dr. H. N. Moyer, 910, 103 State Street, or to the publisher, Geo. S. Davis, Detroit, Mich?

Very truly yours,  
NICHOLAS SENN, M.D. JAS. G. KIERNAN, M.D.  
J. C. HOAG, M.D. H. N. MOYER, M.D.  
W. H. WILDER, M.D.

**Thoracotomy in Sarcoma of the Breast.**—M. Vautrin, of Nancy, at the Congrès Français de Chirurgie, (*Revue de Chirurgie*, November, 1894) said that the indication for thoracotomy presented itself more often than is commonly thought, in cases of malignant tumors of the chest wall. These tumors give a grave prognosis and but little hope of survival, and in their evolution they arrive rapidly at invasion of the lung. This invasion is a contra-indication to operation, and it is a delicate point of diagnosis to determine this point with precision. Superficial tumors of the female breast, rarely invade the deeper structures but sarcoma constitutes an occasional exception. The deep tumors are generally recurrences of carcinomata. The contest is generally abandoned at this stage, although thorough intervention may give results. M. Vautrin has twice practiced thoracotomy under the following conditions:

1. A young woman of 19 years was attacked with a large sarcoma of the breast. In the course of the operation for removal it was seen that the ribs were invaded, and they were removed; it was then found that the pleura was also affected, and it was also resected. The air entered the thoracic cavity and caused syncope. After five minutes the pulse returned and he was able to complete the operation. This patient was cured and remained well.

2. This case was a recurring carcinoma of the breast, having invaded three ribs and seven centimeters of the pleura. These were excised, the sequelæ were simple and the wound was healing by granulation.—*Revue de Chirurgie*, November, 1894.

**Statue of Charcot.**—The pupils and former associates of Charcot in Paris and throughout France are engaged in raising a fund for the erection of a bronze statue of him in the Salpêtrière. This movement is now receiving cordial and material support in Germany, in England and in Italy. It has therefore seemed desirable to the neurologic societies of New York and Philadelphia that the profession in America join in this testimonial as an evidence of the eminent services of Charcot in neurology and medicine. For this purpose the undersigned have been appointed a committee to bring the matter to the attention of the profession and to receive contributions, which will be duly acknowledged and forwarded to the Central Committee in Paris. It is requested that all who desire to contribute to the success of this undertaking send their subscriptions to the members of the committee nearest them or direct to the treasurer, Dr. C. A. Herter, 819 Madison Avenue, New York, before the first day of February, 1895.

For New York.—E. D. Fischer, E. C. Seguin, M. A. Starr, C. L. Dana, C. A. Herter.

For Philadelphia.—S. Weir Mitchell, Wharton Sinkler, Chas. K. Mills.

For Boston.—J. J. Putnam, P. C. Knapp.

For Baltimore.—William Osler.

For Chicago.—Archibald Church.

For St. Louis.—C. H. Hughes, F. R. Fry, L. Bremer.

For Montreal, Canada.—James Stewart.

For Rochester.—E. B. Angell.

For Buffalo.—J. W. Putnam.

For Pittsburg.—Theodore Diller.

For Denver.—Howell T. Pershing.

For San Francisco.—J. D. Hirschfelder.

December 22, 1894.

**Abandonment of Fort McKinney, Wyoming.**—This military post was situated on Clear Creek, a branch of Powder River, about fifteen miles east of the main range of the Big Horn Mountains, two miles west of the settlement of Buffalo and thirty-three miles south of Clearmont, the nearest station of the Burlington and Missouri River Railroad. Its site was a table land elevated about forty feet above the level of the stream and composed of smooth boulders and gravel overlaid by clay. The climate was regarded as pleasant, most of the winter weather being clear and bright; and although the temperature sometimes dropped four below zero these cold spells were of short duration. The average annual

## ORIGINAL ARTICLES.

### LITHOTOMY AFTER PARTIALLY SUCCESSFUL CLOSURE OF EXSTROPHY OF THE BLADDER—SUBSEQUENT CONSTRUCTION OF A PERINEAL URETHRA FROM SCROTAL TISSUE.

Read before the Philadelphia Academy of Surgery, Nov. 5, 1894.

BY JOHN B. ROBERTS, M.D.

PHILADELPHIA, PA.

In March, 1893, a child, aged 8 years, with exstrophy of the bladder, was brought to me at the Polyclinic Hospital for treatment. The mother told me that when 3 or 4 years old he had been operated on at the Children's Hospital. It was evident that some improvement in the condition had been made by this early operation, because the posterior wall of the bladder did not protrude, as is often the case, but formed a rather shallow cup at the base of the rudimentary penis. The flaps had evidently been taken from the surface above the congenital defect and at its two sides, as in Wood's operation, for the cicatrices in these regions were apparent. The urine ran from the bladder over the penis and scrotum, and also escaped from linear sinuses along the top and sides of the thickened tissue which closed the upper portion of the cleft in the bladder.

As a first step in the operation I endeavored to produce a perineal fistule by thrusting a curved needle from the base of the bladder through the perineum, behind the scrotum, and conducting a drainage through the opening so made. The tube was increased in size at various intervals until at the end of two months there was a canal which would contain a rubber urethral bougie of moderate size. I then etherized the patient a second time, and made a circular denudation around the edge of the open bladder. The rudimentary penis, consisting of the spongy body, the cleft glans and cleft prepuce was entirely removed. Cylindrical masses on each side of the opening in the bladder, which appeared to be the representatives of the cavernous bodies, were also dissected away. A piece of soft rubber catheter was then introduced through the perineal opening established by the first operation, and its end allowed to reach the floor of the bladder. The purpose of this procedure was to secure downward drainage of the urine after the edges of the bladder were brought together. Seven deep sutures were next inserted in a manner to bring the denuded edges of the bladder wall into apposition in a vertical direction. The wound was then sealed with iodoform and collodion. The perineal tube, however, soon became blocked with mucus and pus, which was continually flowing from the irritated mucous membrane of the bladder

and was not satisfactory as a drain. I finally passed a drainage tube from one of the upper sinuses directly through the bladder and out of the perineal opening, in order to prevent the sutures in the middle line from yielding. These middle sutures, however, finally gave way, and when the patient passed from observation there was a large opening in the middle of the attempted closure. Some union had, however, been obtained. The perineal opening showed a marked tendency to close.

I did not see the patient again until October, 1894, sixteen months later. At this time the perineal opening had entirely closed and its scar was inconspicuous, but the exstrophy of the bladder was completely covered by the new anterior wall. At about the middle of this wall, which had been constructed in the manner described, was a small opening of sufficient size to admit the end of a large probe. At the upper and right-hand side of the portion of the wall which had been constructed in infancy was a linear sinus about an inch in length. This was situated at one of the points which, when I first saw the child, allowed the urine to escape. There was a little oozing of urine from the small central fistula, but the major portion escaped from the sinus at the upper right-hand border.

The mother said that the patient suffered severe pain, which was evident by his crying at the least touch of the skin in the neighborhood of the central sinus. The insertion of a probe made it evident that the new bladder contained calculi. The child's general condition was poor, and it was evident that he had been suffering greatly. The offensive character of the urine and difficulty of keeping him free from its odor caused me to give him small doses of turpentine, which, as is well known, imparts a peculiarly agreeable odor to the urine. This device seemed to render the patient less offensive to the others in the ward. A few days later I enlarged the opening in the middle of the bladder wall in front and found the cavity filled with calculi. They were ten in number and varied from five-sixteenths to five-eighths of an inch in diameter. Their combined weight when not dried was 195 grains. It seemed to me that the establishment of a perineal urethra lined with skin would afford efficient drainage to the new bladder, and would remain patulous. I therefore determined to cut a channel between the perineum and the floor of the bladder, and turn in flaps of skin taken from the scrotum. As a first step, I incised the scrotum in the middle line and removed both testicles. I then made a puncture downward from the base of the bladder to this scrotal incision. This permitted me to utilize the scrotal tissue for lining the new channel. By two horizontal incisions on each side of the opening, I obtained strips of scrotal skin and superficial fascia half an inch wide and an inch and a half long. To the inner end of these, ligatures

were fastened and the threads carried upward through the new urethra. The cutaneous flaps were then drawn up along the canal into the bladder, and were then sutured on each side of the incision in the middle line of the anterior bladder wall. This maneuver lined both sides of the perineal opening with skin from the perineum to the anterior bladder wall. A drainage tube was inserted to keep the channel patulous, and the bladder and tube were washed out.

No attempt was made to close the opening in the middle line or that at the upper and right-hand side. I deemed it better to leave these open for convenience in flushing the foul bladder cavity. It was my intention to close these at a later period. The edges of the wound in the perineum left by the plastic operation were brought together with sutures, and healed promptly. Antiseptic solutions were used for washing out the bladder and tube, and the patient did well for several days. His temperature was not high, and the drainage through the perineal tubes was quite satisfactory, though not always perfect.

At the end of three or four days he began to lose his appetite and vomited occasionally. He died on the fifth day, apparently from exhaustion.

An autopsy showed disease of the left kidney, which was riddled with small abscesses. The ureter on this side was double, and showed great enlargement of the caliber and thickening of the walls. The pelvis of the kidney and double ureter were filled with pus. Just before the two ureters of this kidney reached the bladder, they united and opened into the bladder by a single orifice. The right kidney and ureter appeared to be normal.

The specimens presented will make the description of the case clear, since Dr. Bannister, the resident physician, removed the whole bladder and scrotum with the attached ureters and kidneys.

I believe this method of constructing a perineal urethra and lining it with skin from the scrotum will be found an efficient device in dealing with these unfortunate cases. It is very probable that the child would have lived if I had taken this step originally,

instead of making an opening into the perineum without cutaneous lining.

#### DISCUSSION.

DR. H. R. WHARTON—I would ask Dr. Roberts if it is not possible that these stones might not have had some connection with the growth of hair on the inverted flap. In Wood's operation the inverted flap often contains hairs, and these may continue to grow as the patient increases in age, and become the seat of calcareous depositions from the urine.

DR. L. W. STEINBACH—I would ask Dr. Roberts what is his theory in regard to the formation of these calculi? What is their nucleus? I recall a case of vaginal hysterectomy where a portion of the posterior wall of the bladder was removed. Within a week the stitches closing the bladder opening were covered with deposits of considerable size, and it was not an easy matter to remove the sutures, incrustated as they were.

### OPERATIVE TREATMENT OF THE DISEASES OF THE GALL BLADDER.

Read at the Meeting of the Military Tract Medical Association held at Quincy, Ill., Oct. 18 and 19, 1894.

BY ALEX. HUGH FERGUSON, M.D.

CHICAGO.

Since the days of Petit (1733) till our own time, very little or no progress was made in the surgery of the gall bladder. To Dr. Bobbs, of Indianapolis, (1867) belongs the credit of being the first to deliberately open the gall bladder for the removal of gall stones; to Marion-Sims (1868) the honor of giving the procedure a scientific name—cholecystotomy; and to Lawson Tait the praise of perfecting its technique as we perform it to-day. It was found that a permanent fistula followed in a certain proportion of the cases operated upon, much to their discomfort, exhaustion, and sometimes even death from the loss of bile. There are certain abnormal conditions which render life loathsome to one's self, and this may be said to be one of them. While it is true that nature had in some cases made an opening into the bowel for the passage of the gall stones and bile, and this resulted in perfect cures, still not until cholecystotomy allowed the escape of bile from the economy, proving a nuisance and a danger to life, did an indication for a new operation—cholecystenterostomy forcibly impress itself upon the surgical world. It was suggested by Nussbaum (1880), performed by Winiwarter (1881), and followed by Monastyrski, Kappeler, Gaston, Harley, Mayo Robson, Colzi, DePage, Terrier, Courvoisier, Frische, Bardenheuer, Czerny, Helfreich, Réclus and others. Some used caustics, others sutures or the elastic ligature, which attempts were all tedious and dangerous. On June 11, 1892, Dr. J. B. Murphy, of Chicago, by a stroke of genius applied with success an invention of his own—the anastomosis button—to establish a bile route between the gall bladder and duodenum, and closed the abdominal wall at the same time. The selection of a particular portion of the alimentary canal—the duodenum, led me on August 3, 1893, when I first used this button to give the name of cholecyst-duodenostomy to Dr. Murphy's operation. *The total extirpation of the gall bladder*—cholecystectomy—suggested itself to Dr. Langenbech, not for malignancy as one would suppose, but for gall stones. In spite of the bitter opposition he received from 1884 to 1889, a fair proportion of surgeons have followed his advice. With this short introduction I shall now proceed to discuss the indications which induce us to perform the above mentioned three principal operations upon the gall bladder, viz.:

1. Cholecystotomy.
2. Cholecyst-duodenostomy. (Cholecystenterostomy.)
3. Cholecystectomy.

Puncture of the gall bladder and crushing of gall stones in the gall bladder could only be mentioned but to be condemned. The crushing or removal through incision of gall stones obstructing the biliary ducts are procedures worthy of our attention. It appears to be inevitable to the progressive development of medicine and surgery, for the scientific pendulum to swing forward or back, responsive to laudations or adverse criticisms, be they just or unjust. By trying, sifting, selecting and carefully studying our own work, and that of others' do we eventually arrive at an approximate value of an operation, and the main indications for recommending it. Be the function of the gall bladder a storer of bile, or the controller of the tension of the bile circulation (Murphy) or both, we know it constantly contains more or less bile; that cholesteroline concretions—the so-called gall stones—frequently accumulate within it, pass down the ducts, causing severe pain and result in grave constitutional disturbances, jaundice, etc., from obstruction; that the gall bladder is subject to diseased conditions; that compression of the common duct by neoplasms, or its occlusion by parasites and pancreatic calculi affect it indirectly; and, finally, we know that this organ may be dispensed with altogether without deleteriously affecting the system. Nearly all these call for surgical aid. *Cholelithiasis* is by far the most common of them. Let us, for a moment, glance at the many dangers of this disease:

1. Colic.
2. Obstruction of the cystic duct.
3. Obstruction of the common duct.
4. Obstruction of the bowels.
5. Dropsy of the gall bladder.
6. Inflammation of the gall bladder.
7. Empyema of the gall bladder.
8. Contraction of the gall bladder.
9. Ulceration into the peritoneal cavity.
10. Cicatricial obstruction of the ducts.
11. The irritation and low inflammation predisposing to cancer.
12. Jaundice and cholemia.

Let the physician who is in the habit of saying to his patients, suffering attack upon attack: "Oh, its only gall stone colic," study these dangers, and then apply the postponement of seeking surgical relief to his own person. The Golden Rule is aptly befitting. Can the milder forms of cholelithiasis be cured without the knife? Why not? Why does this excrementitious substance—cholesterine—not go on to its stercoraceous transformation, and not form stones in the biliary system of ducts? Is it a conservative act, on the part of nature, to prevent absorption of the constituents of the bile in catarrhal and obstructive conditions of these ducts? What is the relationship of a frequent companionship of cholelithiasis and the gouty and uric acid diathesis? What local or blood changes predispose to their formation? What diet, medicine, or hygienic surroundings might prevent them? Solve that question and the surgeon's knife, needle or button will happily be less in demand. Experimental researches in these directions are very enticing and should bring forth most beneficial results. At present,

however, we must content ourselves with the frequent recommendation of an operation—the opprobrium of the healing art.

*When should the gall bladder be explored by opening the abdomen?*

1. For attacks of biliary colic, where the gall bladder has become enlarged, and then suddenly subsided with instant relief to the patient, but no stones found in the stools, and the region of the gall bladder remains tender for several days. This most likely means that a stone in the gall bladder entered the cystic duct, but was too large to pass through it. The gall bladder became more and more filled with secretions from its mucous lining, gradually distending it until the stone was liberated and fell back into the cavity of the gall bladder again, and the mucus and bile found free escape through the ducts. Small stones may pass through and a large one obstruct the cystic duct, giving rise to a similar colic, but if at all slow in descending the common duct signs of the absorption of bile become manifest.

2. For jaundice following one or more attacks of colic. It may be caused by a stone urged on from the gall bladder by repeated attacks, and becoming lodged at the commencement of the common duct. In this instance the gall bladder enlarges steadily for a time, becomes more tense and tender, before any diminution is noticed, and this decrease in size, when it does occur, is very gradual indeed, the jaundice deepening all the time. A stone lodged in any part of the common duct will produce a similar condition.

The following case is a clinical picture of this indication:

In November, 1891, Mrs. Van C., aged 37, came from Dakota to Winnipeg for treatment. She had suffered for twelve years with biliary colic, the attacks became more and more frequent, until she had only two or three weeks' respite. The region of the gall bladder was always more or less tender for years; has had inflammation there several times; the last attack came on six weeks previously, and jaundice has been present since the first few days of its onset. On presenting herself at the Winnipeg General Hospital, after riding on the train over one hundred miles, the first indication was to relieve the pain and inflammatory symptoms which had become aggravated by the journey. She was rather emaciated and profoundly poisoned from the absorption of bile. Her whole trouble was caused by a small stone which, after opening the gall bladder, I removed with forceps from the origin of the common duct. The walls of the gall bladder were fully half an inch thick, friable, and bound down with extensive adhesions. The cavity of the gall bladder was washed out and its walls stitched with the parietal peritoneum and skin, in the usual way. It closed rapidly and she has enjoyed excellent health ever since.

3. For persistent tenderness over the gall bladder. The interpretation of this sign is that subacute inflammation is going on, due to the presence of gall stones. So tender is this region that in some cases even the pressure of the necessary clothing is intolerable. Upon looking into the history of such cases it is found to be that of biliary colic. The condition is likely to be a contracted and thickened gall bladder reduced to the size of the stone or stones within it. There may be points of ulceration or even gangrene. It must be remembered that persistent pain is also characteristic of cancer of the gall bladder. If cancerous, an irregular tumor, slowly increasing in size and accompanied by the subjective and objective symptoms and signs of malignancy makes its appearance.

4. For enlargement. In all cases of persistent and marked enlargement of the gall bladder, an ex-

ploratory incision should be advised. It means that it may contain: 1, an enormous number of stones; 2, clear mucus; 3, pus or mucus-pus and some bile; 4, nothing but bile; and 5, that a new growth is invading it or the ducts, usually cancer. Should the tumor be due to stones, mucus or pus, a history of cholelithiasis is almost invariably elicited but not always. Dropsy of the gall bladder not infrequently occurs without any history of colic, and it becomes enormously enlarged reaching down to the brim of the pelvis. I can recall two such cases:

*Case 1.*—A half-breed woman, 60 years of age, presented herself at my clinic at St. Boniface Hospital, Manitoba, with a movable tumor in the right abdomen, so closely simulating a floating kidney that I could not to my own satisfaction make a differential diagnosis. It could be moved to the region of the kidney, but it could not be felt to slip into its bed as a kidney does; there was no bowel in front of it, and an area of some dullness could be traced to the edge of the liver; three facts which pointed to the enlargement being a gall bladder. On Oct. 21, 1893, an exploratory incision revealed a dropsy of the gall bladder with one enormous calculus which was removed, and the cholecystotomy completed.

*Case 2.*—Mrs. H., aged 45, on whom I performed a cholecystotomy, before the post-graduate class, at the Chicago Charity Hospital on August 21, 1894, assisted by Dr. Burdick, in which a dropsical gall bladder contained four large stones and one small stone. There was a history of chronic constipation and clay-colored stools for twenty years, but no other disturbance until a tumor was noticed nine weeks before entering the hospital, when local tenderness and an uneasiness ensued.

Empyema of the gall bladder is caused by the irritation of gall stones, plus infection. There may be quiescent gall stones, (no symptoms of disturbance) until the person is taken ill with some infectious disease, as typhoid fever, etc., when at some stage of its course or during convalescence, rigors come on suddenly and a tumor appears. In November, 1893, I was called to Morden, eighty miles from Winnipeg, to see such a case. A woman aged about 37 years was down nine weeks with typhoid and convalescing, when pain in her right hypochondriac region came on, followed by repeated rigors, high temperature 104.2 degrees, etc., and the appearance of a tumor. The case was so severe that we dared not venture an anesthetic. Her pulse was 130, temperature 102, greatly emaciated, and had not slept for two or three nights. *I performed a cholecystotomy with the aid of cocaine.* It was interesting to notice that the skin and parietal peritoneum were the only two structures that required anesthesia. The surface of the gall bladder was insensitive to the needle and knife. In this operation I was assisted by Drs. McConnell and Boyle. We found pus, bile and thirty-two gall stones; some large, others small; washed out the gall bladder, and stitched it to the skin. She made an uninterrupted recovery, but there is still a small fistulous track which is troublesome, although not affecting her general health. I have advised her to come to me, to Chicago to have it treated. It may close itself. Should the enlarged bladder contain nothing but bile, the obstruction in the common duct is not infrequently caused by cancer at the head of the pancreas or sometimes by a pancreatic calculus.

These are the clinical features of some of the cases which call for opening the abdomen for diseases of the gall bladder and obstruction of the ducts. The question now arises which operation to select: Cholecystotomy, cholecyst-duodenostomy or cholecystectomy? The necessity of performing either of them must be on pathologic grounds, and the diseased conditions can not to a certainty be known before the abdomen is opened. We have not had the results of a sufficient number of these operations to make a comparison. From a surgical standpoint, cholecystotomy, in suitable cases, is the most rational, the simplest and safest operation, and if it is capable of rectifying the pathologic conditions it should be the one selected. I should choose it:

1. When the cystic and ductus communis choledo-

chus are normally patulous. The gall bladder may have been enlarged with stones, bile, mucus or pus, which should be cleaned out and the permeability of the ducts tested.

2. When the obstruction can be easily removed from the cystic or common duct through the incised gall bladder.

3. When there is temporary obstruction of the ducts with inspissated mucus, parasites, liver flukes, worms, etc. I met with one case of obstruction of the whole hepatic and the commencement of the common duct with hydatid cysts, which could have been removed by opening the gall bladder and rupturing the little cysts with a probe. The man died on the eighth day, of jaundice. The history of the case was obscure. I did not then (1889) feel justified in making an exploratory incision, which I have since regretted.

4. For the temporary relief of distress and jaundice in obstruction of the common duct by a cancer of the pancreas when the patient can stand but little surgical interference without collapsing on the table. The first indication includes the majority of gall stone cases. The operation can be done in one or two sittings. The condition of the ducts can best be ascertained when the gall bladder is opened in one sitting. I think, therefore, that this should be done with but few exceptions.

Cholecyst-duodenostomy is without doubt Murphy's operation, and it is a valuable addition to the surgery of the gall bladder. His ingenious and useful anastomosis button is to my mind the best and safest device that has yet been produced, to establish a new route for the bile into its natural receptacle—the duodenum. Up to the present there has been reported but one death and that one from hemorrhage from torn liver, out of thirty-six cases operated on for cholelithiasis. The button in this situation is constantly bathed with an antiseptic fluid—the bile—and the duodenum is comparatively free from germs, which adds to its safety. For the fulfillment of the following indications it is the most ideal operation that has yet been offered to the profession:

1. When the cystic and common ducts are permanently obstructed, and the gall stones can not be removed through the opening in the gall bladder.

2. When the common duct is obstructed by cicatricial tissue.

3. In cases of biliary fistulæ and chronic recurrent cholelithiasis vesicularis.

4. In cases of perforation of the choledochus into the abdominal cavity.

5. In all cases of cancer of the head of the pancreas obstructing the bile duct, unless too weak to stand it.

I have successfully used Murphy's button in the following cases:

*Case 1.*—On Aug. 3, 1893, at St. Boniface Hospital, I operated on Mrs. McK., assisted by Drs. Hutton, Todd and McArthur. The patient was 58 years of age. There was constant tenderness over the gall bladder, so that the patient could not even bear the clothing; history of biliary colic for four years. Had several attacks in one day. No jaundice. The gall bladder was opened, and I removed one stone. Could feel another in the cystic duct which I could have extracted with forceps, but left it *in situ*. Could feel no irregularities along the course of the common duct. The small sized button was applied and the wound closed. Upon opening the duodenum I could see its mucous rugæ bathed with bile, and I reproached myself for doing that which seemed unnecessary, for the common duct was patulous. She did ex-

cellently, passed the button the eleventh day, and ever since has enjoyed excellent health.

*Case 2.*—Mrs. J. B., aged 56, troubled for six years with gall stones; jaundiced; found stones in gall bladder, cystic and common ducts; removed stones from gall bladder and cystic duct, but not from common duct. Applied the medium-sized button Oct. 16, 1893, which passed on the eleventh day. Her convalescence was uninterrupted and now enjoys the best of health.

*Case 3.*—Mrs. K., aged 58; referred to me by Dr. Flemming, of Brandon; suffered for years; became jaundiced. Operated on Feb. 22, 1894; found contracted gall bladder, bound down by adhesions; removed stones from it and the cystic duct; could not pass a probe, nor water down the common duct. Applied a small Murphy button with some difficulty. Had to dislodge the duodenum from its bed. Button passed on the tenth day. She has been restored to perfect health.

*Case 4.*—Mrs. —, aged 32, had several attacks of colic; became jaundiced from a severe attack. Had inflammation over the gall bladder. Was the patient of my friend, Dr. Knill, of Detroit, Mich. On my way South I called on my old college mate. Went to see his patient and urged operation, which he had already advised. The next day, March 23, 1894, he cut down to the gall bladder and upon removal of a great number of small stones from the enlarged bladder, the ductus choledochus was found obstructed about its middle and low down. I then inserted the small Murphy button and closed the abdomen. Dr. Knill writes me that she passed the button on the twelfth day and now enjoys perfect health.

*Cholecystectomy.*—Total extirpation of the gall bladder has been done upward of seventy times with a mortality of about 20 per cent. It has been removed far too often. Its execution is neither simple nor safe, except in those cases where it should not be done. The fact that the gall bladder contains stones, mucus or pus does not call for its removal. The indications which suggest themselves to me are:

1. Cancer of the gall bladder when it has not yet invaded surrounding tissues, and constitutional dyscrasia not marked.

2. Gangrene of the gall bladder.

3. Possibly it may be safer to the patient to remove a small contracted gall bladder, than to incise it or leave it alone, and this only when the common duct is open and transmitting bile. My experience of this operation is limited to one case:

A Mrs. F., aged 50, admitted to Chicago Charity Hospital on Sept. 1, 1894. Referred to me by Professor Waugh. Three years ago she had two or three attacks of colic; was then free from pain till three months before her admission, when a pain which persisted and increased in severity became established. Six weeks before her admission a tender nodular tumor appeared and was enlarging.

Diagnosis: Gall stones with probable cancer. Operation, assisted by Dr. Burdick, on Sept. 3, 1894, verified the diagnosis. Had to remove a V-shape of liver with it. Died three hours afterwards from shock. It was ascertained that there was no hemorrhage. I should not have removed it, for it was too extensive, and she was much weaker than I had anticipated.

What is best to be done to the stones in a contracted gall bladder and to those impacted in the cystic and common ducts? This is an open question. The gall bladder may be removed when the common duct is free. I fancy no exact lines of procedure can be laid down that would cover all cases. A stone in the common duct that is easily crushed should be dealt with in this way, and they are not always hard to break, as shown by Tait. Should they be easily reached and prominent, in a situation where stitching can be accurately done they may be cut out. Should, however, stones obstruct a contracted gall bladder, the cystic duct, and the common duct all in the one case, there is nothing left but to incise the gall bladder, make an effort to crush or remove those in the ducts, establish an omental tract for a drainage

tube to the skin, and trust to nature to do the rest. If nothing is done, death from jaundice is certain.

I have performed ten operations on the gall bladder, all successful except the one for cancer of the gall bladder.

There is an operation—cholecystocolostomy—in which the gall bladder is communicated with the colon. For the cure of biliary fistulae, emitting but a small amount of bile, it may be safely done. It is not suitable for any other conditions. I have noticed the report of three successful cases:

1. By Mayo Robson for biliary fistula in a woman about 40 years of age, whom he exhibited before the British Medical Association at Leeds in 1889. He did the fastening with sutures.

2. Case by Chevasse in October, 1891, using Senn's plates. The indication was for bile fistula.

3. By Mayo Robson, Sept. 20, 1893, used his modified Senn's plates. Case of biliary fistula.

## ORAL MANIFESTATIONS IN ARTHRITIC AND GOUTY CONDITIONS.

Read in the Section on Dental and Oral Surgery, at the Forty-fifth Annual Meeting of the American Medical Association, held at San Francisco, June 5-8, 1894.

BY L. L. DUNBAR, M.D.

SAN FRANCISCO, CAL.

When I promised to write upon the above subject I did not know that so much investigation of the gouty diathesis was in progress, or I should have hesitated to add my views to those already published, and although the promise was made prior to the publication of Dr. Pierce's paper, what I have to say has been written upon so much since then by able investigators that my statements can only be viewed in the light of added testimony, instead of original matter. From the mass of evidence presented, I am of the opinion that we have erred as a profession in confounding a series of alveolar manifestations under one head. Ever since Dr. Riggs, of Hartford, Conn., called professional attention to that condition of the dental alveoli known as "pyorrhea alveolaris," and variously by other names as "phagedenic pericementitis," etc., the conditions of the oral cavity have been industriously studied by both dental and medical practitioners, with the result that an entirely new classification of its diseases is impending. For nearly two decades it has been the custom of dental practitioners to ascribe every pathologic manifestation in the alveolar region attended by elongation of the tooth, recession of the gums and wasting away of the periodontal membrane, to irritation occasioned by calculus deposits. Almost every practitioner who has been identified with the treatment of so-called pyorrhea alveolaris has assumed the position that the condition was purely local in character, of undoubted calcic origin; differing only in degree of inflammatory and destructive action as the individual constitution is weak or strong.

It is true that mercurial poisoning and scurvy were recognized in their effects upon the alveolar articulation, but these conditions were so rarely brought under the care of dental practitioners that they cut no figure in the study of oral conditions. The influence of heredity was also recognized, but just how this operated was not clearly understood, so calcic it was deemed to be, and as such it has been treated; usually by instrumentation accompanied by local

medication. That such treatment would suffice to remove some of the manifestations where due to calcific deposits at the gingival we all know, particularly when the habits of the individual have been changed by professional direction. But how many cases have been presented with no apparent cause for the condition; which have baffled every effort to relieve when treated as a calcic lesion. In fact, how little is really known by the mass of practitioners of both medicine and dentistry, of the phases of true calcific deposits, or their significance. As is well known, by far the greatest proportion of calculus deposits are harmless, and their precipitation a perfectly natural process. How many realize, however, that there are forms pathognomonic of serious constitutional impairment, presenting in their manifestation diagnostic signs of great value.

The systemic connection in pyorrhea has not been long recognized. The early writers on the subject in most cases adopted the views of Dr. Riggs and his treatment. As this involved asepsis added to the alterative effect of the surgical treatment of the pockets and subsequent medication (usually a mild cautery), much good was done in the early stages of any alveolar lesion of whatever origin. Clinical evidence has not been wanting, however, of its prompt recurrence. In fact, such has been the experience of most practitioners, and many otherwise good men have openly declared that extraction was the only real cure. This has been used as an argument in support of the claim that the disease is local in character, its systemic connection being negated by the fact that disorganization ceased when the tooth was lost.

I do not now expect to add anything new to professional knowledge in the views I shall advance, and shall premise that I have held the opinions here presented for several years, meeting with success enough in dealing with cases coming under my notice to warrant a closer study of those conditions of the dental alveoli that have been combined under the one title of "alveolar pyorrhea," which simply expresses a phase in the progress of some manifestations, as all are not necessarily accompanied by pus; hence the inadequacy of the nomenclature.

Recent investigations will bring us to a full conception of its systemic connection as a local expression of a disturbance in the intercellular fluids. Modern investigation has illumined the domain of cellular morphology, and diseases of all kinds are being traced to their beginnings in the embryonic area. Closely allied to such investigation is a study of nutrition and function.

The "theory of the connective tissue channels" advanced by Moleschott in his "*Krieslauf des Lebens*," which was indorsed by Virchow, is of interest in this connection. Moleschott says: "It is one of the grandest achievements of modern times, to the knowledge of which V. Recklinghausen and Virchow have paved the way, that the connective tissue has been raised from the secondary part which at first was allotted to it, to one of productive activity such as was never anticipated; what appeared formerly only designed as a protecting covering or padding appears now as the bed of the most minute and secret streamlets of juices or sap from the blood to the tissues and back from these into the blood vessels; and at the same time as one of the most important nidi or breeding-place of new cells, which developed from

the embryonic early shapes can rise to form the most peculiar and special structures of the body."

We lose sight of the fact that in the implantation of the teeth in their alveoli we have an articulation in most of its connective tissue relations the analogue of any other articulation in the body. The same influences are at work here as in other members of the same group, and when we consider the nervous relations of this tissue we are prepared for the statement that the vaguely understood effects of arthritis deformans or rheumatoid arthritis may produce their peculiar destructive effect in a degeneration of the periodontal membrane and the alveolar periosteum, as it does in the connective tissues of other articulations.

Drs. Garrod and Weber both ascribe the manifestation of arthritis to trophic influence, which may account for its appearance in one locality, to the exclusion of all other articular surfaces in their immediate neighborhood; as, for instance, in the joints of the plantar and palmar regions and in the maxillary articulations. I submit, therefore, that in view of tissue relations such manifestation may occur in the dental-alveolar articulation. I have seen such cases, and while presenting clinically much the same appearance that we have recognized as alveolar pyorrhea, still an analysis of the animal fluids did not disclose the presence of uric acid. "In all cases of arthritis deformans the serum of the blood has the ordinary properties of the serum of healthy blood, and an analysis of the urine likewise gives negative results, while nodosity is a pathogenic feature in arthritic cases; no deposits of urate of soda are found in any stage of the disease."

Dr. Garrod says that "he is persuaded that statements to the contrary are erroneous," admitting, however, "that it is not impossible that a patient may have had gout in a joint with its accompanying deposits, and that afterwards the same articulation may become the seat of arthritis but this, if indeed it ever occurs is most rare, and would not in any way favor the idea that deposition of urate of soda is a phenomenon of this form of inflammation."

It is not my purpose to enter into a detailed description of the disease known as arthritis deformans, which is the accepted name for the condition, but only to point out a possible source of an oral lesion. Dr. Garrod called the disease rheumatoid arthritis, and gives many reasons for the adoption of this title, but does not lay as much stress upon its tropho-neurotic origin as Weber, who has had excellent results with tonics and the application of the galvanic current to the spine and cervical ganglia.

The morbid anatomy of this disease has been carefully studied by Volkmann and Adams, (see Garrod), and their observations show that from the very commencement of the inflammatory action the articular cartilage begins to suffer, a slow process of absorption seems to take place, the cartilage splits up into fibers vertical to the surface of the bone, little depressions occur which at length coalesce and the bone is left in part uncovered. As the disease progresses the whole surface may be thus denuded, the osseous surfaces brought in contact with each other and in the movements of the articulations they become polished by friction and an ivory-like condition called eburnation is produced. This is the cause of the crepitation in joints so affected, and enables the practitioner to verify his diagnosis in

differentiation with gouty or rheumatic affections. In the earlier stages the disease may be and often is confounded with these two last named inflammations; an examination of the fluids and the progressive character of arthritis, if not arrested, will make diagnosis easy.

Where the manifestation is in the alveolar-dental articulation it probably has its origin in the trophic center in the spinal cord corresponding to the part affected, and I see no reason why this inflammation may not make its first appearance in the dental articulation, as in any other articular surface. To the pocket once formed there is added those septic complications, varying with the habits of the individuals affected, that produce a likeness and make the difficulty of diagnosis greater.

When a better knowledge of the nervous relations of the teeth has been acquired, I feel quite certain that many doubtful oral conditions will be better understood and properly classified. In this connection I am impressed with the necessity for instruction in neurology as a part of the curriculum of our modern dental schools, where scientific training is paramount to purely constructive work.

In reference to gouty manifestations in the oral cavity, the recently published results of the investigations of Drs. Pierce, Kirk, Burchard, Faught and others furnish such a fund of information upon the subject as to leave no doubt in regard to the effects of retained uric acid in the circulating fluids.

In the light of the before mentioned theory of Moleschott, we can understand how the peridental membrane may become the seat of such deposits as urates of lime and soda. The office of the membranous groups represented by the periosteum and pericementum is the deposition of lime salts. In mild inflammatory conditions, not accompanied by perversion of the circulating fluids, there is developed an activity in the pericementum that results in an increased deposition of cement beyond the typical limits of the root in similar inflammations of this membrane, caused by or accompanied with an excess of urates in solution in the circulating fluids. We can understand how a deposition of salts of calcium may be made that would show upon analysis the presence of urates; indeed, we have no assurance that the presence of morbid materials in the blood would not cause the specific inflammation that induces the deposit with its inflammatory coloring.

In my experience, the deposit known as serumal calculus is not removable by any means at our command that would not be equally destructive to the surrounding tissues. In pockets of long standing freely accessible to the fluids of the mouth and to oral *débris*, there may be an added deposit on the surface of a root in granular form that is removable. This, however, is only manifested in the last stages of the disease when re-attachment is doubtful.

Where the pocket is manifested on but one side, and all removable deposit has been carefully taken away, I do not think that the loss of that limited area of peridental membrane offers any barrier to return to health of the surrounding tissue and entire attachment of the tooth.

It was my intention to have presented something more upon the gouty diathesis, but as the ground has been so well covered in recent publications in our professional journals, I shall not hope to bring you anything new, and trust the discussion may more

fully develop a subject fraught with so much of interest.

How much the uric acid diathesis has to do with other destructive oral manifestations has not been determined, but I am convinced that some specific acid condition of the circulating fluids is the cause of that mysterious wasting away of the enamel so frequently met with, and which in description of what really occurs, we denominate erosion. What we now recognize as alveolar pyorrhea in its several manifestations, I have shown, or endeavored to show to be due to any one of two or three systemic conditions requiring a different classification and a nomenclature suggesting in part its origin. When this has come to be scientifically developed, an entirely new system of treatment for each will be evolved. Already the study of this subject by dental practitioners has been the means of introducing an entirely new salt of lithium, as an addition to the materia medica. I refer to the preparation known as tartarlithin or lithium bi-tartrate, first made by Dr. E. C. Kirk, of Philadelphia, a practicing dentist and an expert medical chemist. In fact all the information we have up to this time upon the oral manifestations of the uric acid diathesis is due to dental investigation. What the dentist can do for these conditions will depend upon his preparation for practice and his conception of its scope; certainly instrumentation is not to be entirely relied upon. Primarily this was designed to be only a process of cleansing and not instrumentation in its surgical sense. To be entirely successful therefore means a wider knowledge of systematic conditions and also the ability to recognize the pathologic significance of oral lesion. Are dentists properly prepared for such work? Or does the purely constructive or prosthetic secure the largest share of attention in our technical schools? We think that the curricula of our modern schools of the best class comprise all that is essential for such a training. Where they do not, the instruction in physiology, pathology, and histology can be strengthened; if not, the schools of medicine are open for post-graduate instruction with liberal allowances for work already done, thus enabling the dental graduate to complete his preparation for practice upon its highest plane.

## DOUBLE NASAL ATRESIA DUE TO SMALLPOX.

Read before the Mississippi Valley Medical Association, at Hot Springs, Nov. 20, 1894.

BY HANAU W. LOEB, A.M., M.D.

ST. LOUIS, MO.

One-sided nasal atresia due to smallpox is uncommon enough in rhinologic literature, and as double nasal atresia caused by smallpox must be all the rarer, I am prompted to present the details of this most interesting case to the Association. It is all the more desirable for presentation on account of the success of the treatment, and the great relief which the patient has experienced, for we all know the difficulty of maintaining an opening which nature once has closed.

We read, with remarkable monotony, of failure after failure in the treatment of webbed fingers and conditions due to the deposit of scar tissue; we realize quite readily the almost futility of the treatment for the permanent relief of cicatricial contractions and adhesions, resulting from syphilitic lesions of

the pharynx, palate and larynx, so that while no great skill is claimed in the management of the case in point, yet the patient's condition after a year and a half of observation certainly merits attention:

Miss E. T., age 30 years, consulted me first on April 6, 1893, with the following history: Twenty-nine years ago she was subjected to a severe attack of smallpox, which very seriously affected her health. The disease was of the confluent type, and exhibited itself more upon her face than any other portion of her body. There had evidently been a coalescence of a number of pustules over the alae of the nose, and the portion of the lip which is in immediate relation with the nose. Considerable scarring naturally resulted, mainly exhibited on the face, especially in the region of the nose and lips. She had several scars upon her body, arms and lower extremities, but none manifest the degree of cicatrization that is to be found in those upon the face. The result of this loss of tissue was a very decided contraction of the nasal orifices, so that they were no larger than a broom straw.

Five years afterward, an attempt was made by a prominent surgeon to enlarge the openings of the nostrils. For some reason the only effect was to completely obliterate the openings, so that for the past twenty years she has been absolutely unable to breathe through her nose.

Since that time the patient has been in fairly good health,

with the exception that she has been suffering from a dry throat which was especially severe early in the morning; so severe in fact, that she was prevented from partaking of an early morning meal. She suffered very frequently from headaches, which were localized to no particular part of the head. Strangely enough she was not subject to acute pharyngitis though her throat, she said, was a source of continual trouble. She has not been subject to bronchitis, and she has never had pneumonia or any serious illness since her attack of small-pox. During the two years previous to the time she consulted me, her symptoms were somewhat aggravated, and the dryness about her throat had increased. The hawking and clearing of her throat which were almost continually a source of annoyance to her were decidedly increased, and, as she expressed it, she was much sicker during this time than before. She fails to relish her food from a lack of taste.

Examination revealed very plainly the effect of the attack of smallpox. Numerous scars were to be found like the ordinary marks resulting from the disease but, as has been stated before, they were larger and more prominent on the face. Examination of the pharynx showed a chronic inflamed pharynx of a mild type, and with numerous spots of folliculous inflammation. The naso-pharynx was also affected with a chronic inflammation, but the larynx did not exhibit any evidence of disease. It was made very man-

ifest that behind the point of atresia the nasal cavities were open and free, for the patient could easily balloon out the soft parts by forcing air from the pharynx into the nose. In this way too, it could be shown that the overgrowing tissue was perfectly impervious, for the swelling produced by blowing was not reduced until the patient ceased her efforts. The voice was quite clear, and indeed it was only by close attention that an obstruction would be expected.

The patient, having consented to an operation, was sent to the Rebekah Hospital, and upon April 27, Dr. H. C. Dalton operated in the following manner: After aseptic preliminaries, an incision about half an inch long was made through the cicatricial tissue, somewhat larger on the left side than upon the right. It was necessary to make a larger incision upon the left side, from the fact that the left ala had collapsed considerably on account of a greater destruction of the alar cartilage upon that side. The skin and mucous membrane were then stitched together, around the improvised openings, leaving on each side a fairly normal looking orifice. Into each nostril was introduced a rubber tube, devised by myself after the plan of Simrock's speculum, being, however, about one-third larger, and having a larger rim or flange. Into this flange four small openings were made for the purpose of inserting threads. The two tubes were sutured to the adjacent skin, so as to be certain that they would be held in place. The whole was covered with

gauze, and the patient put to bed. She suffered from very slight inconvenience, and after four days the sutures holding the tubes in position were removed, and the whole nose subjected to a thorough cleansing, after which the tubes were re-introduced.

They were now held in position in a somewhat different manner. The thread was placed in the two inner openings, holding them close together, and another thread into each of the two outer openings in the flange and these were carried behind the head and held firmly by a hairpin. This method was found to be eminently satisfactory, very slight displacement being possible. The tubes were easily kept in place, and from their form were not at all inconvenient or uncomfortable to the patient. She left the hospital after three weeks, the wound being entirely healed, and the margin of the new nostrils being smooth and normal. She continued to wear these tubes constantly for three months, being warned of the danger of a reunion of the two sides of the nostrils. In three months she was permitted to leave the tubes out for an hour at a time; later this time was extended. Meanwhile the patient was looking very much better, and as a matter of course, she suffered from no dryness of the throat, and from none of the other symptoms which were so unpleasant to her. Her headaches entirely disappeared, and her sense of smell returned. She was able to

appreciate the odor of flowers three days after the operation.

On March 31, 1894, a second operation was performed upon the left side, as it was evidently not so satisfactory as the right nostril, a fact easily explained when it is remembered that so much of the alar cartilage was destroyed. The incision was carried somewhat higher up toward the tip of the nostril than it had been, and a slightly larger tube was inserted. This operation has had a decidedly good effect, and now the left nostril is almost as perfect as the right. Since July 1, she has not worn the tubes during the day, now four months. Examination on September 15 revealed no evidence of any return whatever to the original condition. It was suggested to her that she might leave the tubes out altogether, but since she is rather fearful lest her old condition might return, she prefers, at least for the time, to wear them every night.

The illustrations which are presented, exhibit the appearance of the case with the tubes inserted, and the appearance of the nostril a year and a half after treatment. The picture showing the condition of the nose before the operation is not a very satisfactory one, being taken from an old photograph, of some ten years ago.

I am quite certain that the good result in the present case has been due to two circumstances: In the first place the mucous membrane and the skin were united, the skin being rather redundant, and therefore capable of forming a good protection for the margin of the nostrils. If there had been less skin, I am quite certain that the result would not have been quite so pleasing, but with the redundant tissue it was reasonable to expect so good a result. In the second place, the tubes which she wore subjected the nose to no pressure, and maintained their position without

any degree of irritation. They fulfilled their function so nicely, that I would commend a similar tube in any case of a like nature.

321 North Grand Avenue.

## CASE OF FRACTURE OF ANATOMIC NECK OF THE HUMERUS.

BY E. L. GIBSON, M.D.

STAUNTON, VA.

A 16-year-old boy, of good build, fell about twenty feet into some ladders. I saw him about two hours after the injury; he complained of great pain at the shoulder joint. A slight contusion was seen on the front of the arm at the shoulder joint; I was unable to find any other contusion.

On superficial examination, I thought I had a sub-spinous dislocation; but the protrusion did not look as large as would be expected. To isolate fracture, I placed the fingers of one hand on the bicipital tuberosities and rotated the humerus; they were felt to move under my fingers; no crepitation was elicited in this way. Dr. J. St. P. Gibson saw him at this time and confirmed my diagnosis. He was given chloroform; reduction was effected by Koker's method after several trials. Rotation was now made and crepitation was very perceptible.

Treatment: Gibson's wire splint, which was described in the Transactions of the Ninth International Medical Congress, Vol. I., page 585, was applied.

By this means, extension was continued for four weeks, at which time the wire splint was removed and a pasteboard crown splint was applied and allowed to remain two weeks. Upon its removal the deltoid muscle was found much atrophied; allowing the head of the humerus to be examined thoroughly. A line of callus could be felt. The joint admitted of all motions without pain and a perfect shoulder is the result. The crown splint will be retained for a couple of weeks longer, allowing slight motion.

## SANITARY LEGISLATION.

Abstract of Remarks before the Auxiliary Health Association, Springfield, Ill.

BY CLARKE GAPEN, M.D., LL.B.

KANKAKEE, ILL.

As I look back over the twenty years of my life and work in medicine, I find that nothing has grown upon me more steadily or forcibly than the belief that the future of medicine is to be largely in the field of sanitation. The medical man who has kept himself abreast with the times has seen one line of treatment and one theory after another give way. My worthy preceptor who presides here, twenty years ago taught me many things that to-day he would declare worthless. All of our teachers have taught us much with regard to medical treatment which has since vanished into thin air like the baseless fabric of a vision, but in all this time sanitation has steadily grown in importance until to-day in practical significance it is not secondary to any other thing, even in medical instruction.

The fact that my experience in the line of sanitary work has been somewhat extended and peculiar, is my only excuse for offering ideas of so positive a character as those which I now present. Beginning with an almost absolute sanitary chaos, in a city of

150,000 people, I passed through the experience of the organization of a sanitary department which in the end was practically complete. My first step was to familiarize myself, as far as possible, with what had been done in sanitary work throughout the civilized portion of the world. After doing this and formulating a definite plan, we went directly to the Legislature for the basic law upon which to construct our sanitary organization; and looking back over that work after five years, I now think that that was the wisest thing we could have done under the circumstances. This, you will see, is diametrically opposed to a view which has been expressed here to the effect that the work should be begun with the education of the masses.

In my opinion it is far better to begin work at the other end of the scale. Ideas of sanitation, like all other advanced ideas, must begin at the top and work downward. There is no such effectual educator as law. By that, I do not mean that we should go to the Legislature and get a vast number of statutory laws enacted. Such a proceeding would break down the whole organization which would fall, as it were, of its own weight; but there should be formulated and enacted by the highest legislative authority in the land, laws containing the basic principles of sanitation. This done, you have a foundation on which you can proceed to educate the masses. In all sanitary work the greatest obstacle to be met is the ignorance of the people in reference to sanitation. There is opposition to sanitary work to be found everywhere that it is attempted. It is, however, not malicious. As an illustration, comes to my mind the conditions now prevalent in Milwaukee. The intelligent people of Milwaukee are not opposing the enforcement of the sanitary laws. It is the ignorance of Milwaukee that is opposing and even antagonizing the State law itself. If the authorities there had no surer foundation than the excited state of public opinion that prevails there, the Department could not exist. Such existence as it has is based upon the enactments of the State Legislature. In our work in Omaha, we first formulated the law which was passed by the State Legislature. This law created in all cities of a given class, sanitary departments, and fixed the character of the organizations which should control and operate them. Upon this law the local organization was founded. This local organization then proceeded to enact a sanitary code, which was to be the law of the territory controlled by this sanitary organization. I think that you will find that these three steps will have to be taken in just the order named.

So far as the work of this organization is concerned, I feel that it has not been begun a moment too soon. It should meet again at an early date to formulate a plan and complete an organization which should have an active representative in every locality, and which representative should exercise an influence upon the member of the Legislature from his district, with the object of bringing about during the coming winter a definite legislative result, in the form of such basic laws as are necessary to the organization of sanitary departments in every portion of the State. First in importance, in this legal enactment, should be the recognition of the principle that *sanitary organizations should be based upon State law instead of upon municipal law*. There is nothing so unreliable, nothing so certain to defeat the objects in view as municipal law. Municipal law is one thing

to-day, another thing to-morrow. A board of aldermen may formulate a law to-day, which in order to get a particular individual out of office it may repeal within a month. No organization is safe or efficient which is founded wholly upon municipal law in this country.

As to whether each town, city or county should have a board of health is a somewhat open question. I am inclined, however, to think that the existence of a board of health at least in every good-sized town is desirable. In our organization, after much deliberation, we concluded that it was wisest to have such a board in every city of the first class. However, as I have indicated, a good and efficient sanitary department may be operated without a board of health, the head of such department being an officer with power to execute both State and municipal enactments.

Another and most important provision *which should be included in the basic law*, is a provision for the maintenance of the office or department. It should be as impossible for local influences to cut off the support of such department, as it is for them to abolish it. As I look back over the work in Omaha, I feel that this was the one particular in which we fell short. We asked the Legislature for a tax of 1 mill upon every \$100 of taxable property for the maintenance of sanitary departments. We succeeded, however, in getting only  $\frac{1}{2}$  of a mill. This tax amounted to a sum sufficient to meet the salary of the executive officer and the necessary expenses of the office, but was not sufficient to provide for as extensive sanitary policing of the city as was desirable. The extra provision had to be made up out of the city's treasury by the common council and fluctuated in amount in accordance with the state of feeling existing in that body toward the sanitary department. All who have been engaged in sanitary work in cities know that it is a custom for ward politicians to "load up" the sanitary departments with irresponsible individuals, good for nothing else, and good for nothing there. Attempts to build up a sanitary department upon the basis of merit strictly, are met with opposition from members of the council who have friends for whom they wish to secure soft berths. The statutory provision should make it impossible for local influences to thus cripple a Health Department. I mean by this, that taxes for the support of a sanitary department should be levied in the same manner as the school taxes are levied. It is impossible for a city council to reduce the school tax below a given point, and this should also be true with reference to the funds necessary for the support of sanitary departments. I think, however, that at this point State interference should cease, just as State interference ceases in reference to school matters when it has made the maintenance of schools obligatory upon each town or city, and has made provision for their support by taxation. The appointment of the executive officer of the board or department of health should therefore, in my opinion, rest with the mayor, and the term of office of this official should be co-existent with the term of office of the mayor. There are two methods of forming a board of health. The one being the appointment of worthy citizens to compose the board who have no direct connection with the city's affairs. The other is by forming the board of officers who have a direct connection with the city's affairs. Of these two

methods, I prefer the latter, for the reason that officers who have a direct and paid connection with the city's affairs are much more likely to give attention to them and to keep themselves familiarized with them than the other class of citizens whom I have mentioned. To my mind, an ideal board of health should be composed of the mayor, chief of police, two representatives of the common council and a commissioner of health, who shall be the executive officer of the board.

The next step is to formulate a sanitary code. I spent some nine months studying the sanitary codes of the various cities of the world before formulating the code adopted by the board of health in Omaha, and acquired what was to me, some very interesting information. The first thing that impressed me was the wide difference between municipal government in this country and in Europe, for example,—the city of Birmingham in England, has a municipal government which is said to be a model one, that costs less than \$5 per capita per year, and the superb city of Munich is maintained at about \$13 per capita. The municipal administration of the city of New York costs about \$25 per capita, or five times as much as Birmingham, and as every one knows is most inefficient and corrupt. The same may be said of most of the large cities of this country. In my opinion the next great reform that will sweep over this country will be municipal reform.

Model sanitary departments are found in Berlin, Munich, Glasgow, Birmingham, and numerous other European cities, but are to be found in none of our American cities. Glasgow has one of the best health organizations in the world, which deals with exceptionally difficult sanitary problems, and is maintained at a cost of about \$500,000 per year. In this country, the model State board of health, and in fact, the only State board of health that exists with anything like full powers and support is that of Massachusetts. The States of Minnesota and Michigan each have, however, health departments worthy of study and consideration. In the great State of Illinois with a population of 6,000,000 people; a State possessing the greatest resources of any State in the Union, perhaps, the members of the State Board pay their own expenses. Provision should be made to maintain in this State a board of health in keeping with the character and resources of the State. A sufficient provision should be made to pay the members a per diem for actual service and to maintain an office, chemic and bacteriologic laboratories, and all necessary medical and other skilled supervision, and to insure competent sanitary inspection wherever needed. In short it should be provided with authority and support.

The State Board of Health of Massachusetts maintains at Lawrence a complete department for the examination of water, and this department has contributed more to the knowledge of the purification of water than any other body of scientific workers in the world. It has furnished the facts upon which water purification is based all over Europe to-day, though, strange to say, these facts have so far excited comparatively little influence in this country. A department is also maintained in connection with the Boston Polytechnic Institute for the examination and study of foods. To the water department may be sent the water of any village or farm-house and the people may know whether they are drinking safe

water or not. To the food department the citizen may go for information in reference to all questions of food adulterations. An organization should be effected whose voice will be heard from the northern boundary of the State to its southern limit, demanding in language that can not be misunderstood that something may be done in relation to sanitation worthy of our great State.

# ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 55.)

## CHAPTER III.

None of the tables in the article of Dr. Faget support the assertion in the article, "Fevers," of the new French Dictionary of Medicine (1871): "In some fevers the remission is long and complete, as in yellow fever, for instance, in which the *initial attack* is separated from the *terminal fever* by a *remission* of one or several days duration." (Vol. XIV., p. 742.) On the contrary, according to Dr. Faget, "yellow fever shows *one single effervescence*—only *one paroxysm*, never a true remission, and the *unique attack* subsides immediately. Its progress is regressive as soon as it appears. This last peculiar feature would not show as plainly in our tables, but for the fact that they often begin after the second and even third day. The fact is that the decline is marked from the very beginning, in the line of the fever only; as for the temperature we shall see that it even increases, at least, in two-thirds of the cases during the first two or three days. . . . The thirty-eight observations of 1870 also contradict the opinion concerning the *short duration* of yellow fever. According to La Roche's opinion, based on immense learning, it would be three days ( $3 \times 24 = 72$ ): A febrile stage of about seventy hours' duration, more or less, is succeeded by a period of complete cessation of fever (Vol. I., p. 426). Judging from our tables, it should be six or seven days ( $6 \times 24 = 144$  hours): "The maximum of temperature in yellow fever, in New Orleans in 1870, has been, in the average of cases, 104.1 degrees. Such is the average maximum of fevers in general; there is, therefore, in this, nothing peculiar in yellow fever. The particular and special feature is that: 1, this average maximum of temperature is very rapidly reached in yellow fever cases. In about one-third of our cases (twelve in thirty-eight) the maximum has been reached on the very first day; in one-fourth of the cases (nine in thirty-eight) it was on the second day; in another third of cases (fourteen in thirty-eight) on the third day; and in three cases the disease had gone over three days before reaching its maximum, and it went on steadily decreasing till it reached the normal standard, and even below that point, except in cases where special circumstances or accidental causes easily accounted for, such as secondary congestions appeared. Thus we can say that there exists no stationary stage in yellow fever. The decrease of the temperature has been remarkably slow. Up to the fifth day it had not yet reached the normal standard in most of our cases.

The exceptions were such as were very mild, or such as proved rapidly fatal. In twenty or thirty the thermometer registered 100 or 102 degrees on the fifth day. . . .

"In short, the march of the temperature in our tables is marked: 1, by a period of increase, very rapid and of very short duration; and 2, by a period of decrease, rather slow and long. There is no sign of a true stationary stage. Thus the study of temperature in yellow fever offers for our consideration only an effervescence and a defervescence. . . .

"I shall sum up in saying that, the march of the temperature in yellow fever, as shown by the graphic lines representing it, is characterized by a unique paroxysm with an effervescence of one to three days, followed by a defervescence of four to seven days, without any stationary stage. . . .

"We consider that we are now authorized to say that in yellow fever we are able, in the majority of serious cases, to detect from the beginning of the fever, one of its most precious diagnostic signs, and that is the divergence of the lines indicating the march of temperature and pulse. The line of the pulse descends immediately, while the line of temperature ascends, and that during one, two or even three days. . . .

"But I shall insist upon saying that the direction of the lines of temperature and pulse is of special importance in the incipient stage of the febrile paroxysm of yellow fever, in view of the diagnosis of the disease. In the great majority of serious cases, the line of pulse descends, while the line of temperature ascends. Are we not justified in our belief that there very likely exists no other disease in which the same occurrence obtains? . . .

"Let us now consider the specific character of yellow fever, which shows itself in our opinion, by the action of its morbid principle on the heart, this action being denoted by a diminution in the number of pulsations from the very beginning. . . .

"In the work that I published on yellow fever in 1859, after having studied the progress of the fever, without the thermometer, guided only by statistics of the pulse, and those statistics compiled from at least a hundred observations, taken by a dozen physicians during the epidemics of 1839, 1853, 1858, I expressed myself in the following manner (p. 85): . . .

"In all these observations written at the bedside of the patients during three different epidemics in New Orleans we perceive, nearly without exception, that the pulse at its *apogee*, from the first day gives even more than 100, sometimes 110 and 120 pulsations; begins to fall the second day, continues to decrease regularly the third, and gives from that time 70 to 80, sometimes much less."

"The regular and rapid decrease of the pulse is such in yellow fever, from a record of a hundred observations, that we could recognize it as the true characteristic of that fever. . . .

"To-day, after the epidemic of 1870, that is to say, after having been able to study the progress of yellow fever, not only with the 'independent second watch,' but at the same time with the thermometer, I think further hesitation is impossible; the diminished frequency of the pulsations, that is to say, the heart's action, show themselves from the beginning in yellow fever, and consequently in the height of febrile excitement, as certified by the thermometer. This is the essential characteristic of this fever, . . .

and, in fact, a like decline of the pulse is not a simple abatement of the fever, since it occurs in the great majority of cases during the increase of temperature. We find, then, a diminution of the beats of the heart, produced by a direct specific action of the poison itself of yellow fever, in the central organ of circulation. This specific action of yellow fever poison on the heart can be compared to the effect produced on that organ by certain poisons, as, for instance, digitalis and veratrum viride. . . .

"Now the specific character, clinically demonstrated has just received the most remarkable anatomic confirmation in the observations upon yellow fever (just published by Prof. Joseph Jones, of the University of Louisiana). This is what he says on page 8 of his pamphlet: "The central organ of circulation is structurally altered and enfeebled in yellow fever, the muscular structures of the heart present alterations similar to those observed in the liver and kidneys. Oil, granular, albuminoid, or fibroid matter is deposited within and around the muscular fibrillæ, and the organ after death presents a yellow flabby appearance. These lesions of the heart, shown by careful *post-mortem* examination, are characteristic of the disease." . . . The general table of the average of the pulse, furnished by Blair, like ours of New Orleans, not only shows the steadily decreasing character of the pulse in yellow fever, but it also demonstrates beyond a doubt that this fever has but one paroxysm, and consequently it is a continued fever, continually decreasing but still continued. . . . "If, then, yellow fever remained a fever with but one paroxysm, in Guiana as well as in New Orleans, it proves it not only to be a continued fever, but one that resists efficaciously the concomitant influences of malarial fever." (Type and Specific Character of True Yellow Fever, *New Orleans Med and Surg. Journal*, September 1873, pp. 145-168.) . . .

Dr. D. D. Saunders, of Memphis, Tenn., in his valuable "Observations on the Yellow Fever Epidemic of 1873 at Memphis, Tenn.," gives a tabulated record of the pulse and temperature in seventy-three cases of yellow fever. The daily average of the temperature and pulse, was as follows: First day temperature 102 degrees; pulse 114½. Second day temperature 102.5 degrees; pulse 112½. Third day temperature 102.2 degrees; pulse 107½. Fourth day temperature 102 degrees; pulse 96½. Fifth day temperature 102.2 degrees; pulse 86½. Sixth day temperature 101.5 degrees; pulse 74. Seventh day temperature 99.5 degrees; pulse 69½. Eighth day temperature 99 degrees; pulse 68. Ninth day temperature 97.8 degrees; pulse 64½. Tenth day temperature 98.1 degrees; pulse 65½. Eleventh day temperature 98 degrees; pulse 67½. Twelfth day temperature 98.2 degrees; pulse 71½. Thirteenth day temperature 98.5 degrees; pulse 80. Fourteenth day temperature 98.5 degrees; pulse 82. . . .

In ten fatal cases the daily average of the temperature and pulse was: First day temperature 105 degrees; pulse 120. Second day 105.5 degrees; pulse 120. Third day temperature 105.7 degrees; pulse 116½. Fourth day temperature 106.5 degrees; pulse 114½. Fifth day temperature 104.6 degrees; pulse 106½. Sixth day temperature 103 degrees; pulse 100½. Seventh day temperature 102.8 degrees; pulse 99. Eighth day temperature 101 degrees; pulse 99½. Ninth day temperature 97.5 degrees; pulse 81. Tenth

day temperature 99 degrees; pulse 100. Eleventh day temperature 98 degrees; pulse 120. Twelfth day temperature 97 degrees; pulse 130. Thirteenth day temperature 96 degrees; pulse 130.

Of the ten fatal cases, five died on the fifth day of uremia; one died on the sixth day, of uremia; one on the seventh day, of nervous prostration; one on the ninth day, of uremia; one on the tenth day, of uremia; and one on the fourteenth day, of uremia. No case of uremia lived over fifty hours, after urinary suppression set in.

Dr. Saunders remarks: "The tables accompanying this report show yellow fever to be a full fledged fever within a few hours after its initiation, and the circulation is as rapid then as it ever gets to be unless complications arise, as in the winding up of the fatal cases. The pulse begins to diminish in frequency within a few hours of the beginning of the fever, and in the stage of convalescence will descend below the normal standard. I saw it descend to thirty-six beats per minute and the patients recovered. The temperature, however, will generally either hold its starting point, or gradually ascend from 72 to 120 hours, and then if there are no complications, begin a gradual descent with the pulse, and go below the normal standard of 98.5 degrees in convalescence. I saw the thermometer descend below 95 degrees, and the patient recover. In these cases when the pulse and thermometer descend gradually together, after the second day, no apprehension of danger need be entertained; they will always get well. Such was the result of my observation. . . . I saw no case of yellow fever recover when the thermometer marked over 106 degrees, on the first and second visits, and I saw no fatal case when the pulse and the thermometer gradually descended together below the normal standard.

"I believe with Prof. Joseph Jones, that when the temperature ranges very high from the first, the patient may die suddenly, overpowered by the poison, as in cases of sunstroke."

The results obtained by Dr. R. W. Mitchell,<sup>47</sup> of Memphis, Tenn., and by Prof. Samuel Logan<sup>48</sup> at Pensacola, sustained those previously announced by Blair and others. Dr. Mitchell gives a valuable table of the daily variations of the pulse and temperature in forty-eight cases of yellow fever, the general results of which will be more fully examined hereafter.

With this general historical introduction we will proceed to present specific details and the results of original investigations. The general results of my investigations upon the changes of temperature and conditions of the pulse in yellow fever may be formulated thus:

The maximum elevation of temperature is attained upon the first, second, and third days of the disease; ranging, according to the severity of the attack, from 102 degrees to 110 degrees in the axilla; and, as a general rule, from the third to the fifth day steadily falls and sinks down to the normal standard, and even below. In some fatal cases it rises again toward the end, rarely, however, reaching or exceeding, during the stage of passive hemorrhages, black vomit, jaundice, and urinary suppression, 104 degrees, and, as a general rule, never attains the high degree of temperature characteristic of the first stage. The supervention of an inflammatory disease, or the occurrence of an abscess, or the access of malarial fever,

after the first stage, may in like manner cause a progressive elevation of temperature, with slight evening exacerbations.

The pulse at the commencement of the attack is rapid and full. The frequency of the pulse does not, however, as a general rule, continue to correspond with the elevation and oscillations of temperature, as in many other febrile diseases; and in many cases of yellow fever the remarkable phenomenon is witnessed of the pulse progressively decreasing in frequency, and even descending below the normal standard, while the temperature is maintained at an elevated degree; and on the other hand the pulse frequently increases in frequency, but diminishes in force, near the fatal issue. The occurrence of copious hemorrhage from the stomach or bowels may be attended with sudden depression of temperature, and increase in frequency with diminution in the force and fullness of the pulse.

The remarkable progressive decrease in the beats of the pulse after the first stage in many cases appears to be due to several causes; as the anatomic changes in the heart (acute fatty degeneration), and the retention in the blood of the bile and urinary constituents.

If the temperature rises in the first stage above 105 degrees, the patient is in imminent danger; and if it reaches from 107 degrees to 110 degrees, death is inevitable, whatever may be the treatment adopted. In cases attended with the rapid rise of the temperature to 106 degrees and beyond in the first stage, death sometimes occurs suddenly, and apparently solely from the effects upon the blood and nervous system of the great elevation of temperature, as in sunstroke. The truth of this statement will best be illustrated by actual observations, and especially by the following case, which has recently occurred in my private practice:

Mrs. W., aged 28 years, has resided in New Orleans eighteen months; large, well-developed, with clear complexion and high color in health. Mrs. W. called at my office July 21, stating that she had just passed through the menstrual period, which had been protracted for ten days, was very profuse, and had confined her to bed. She complained of great weakness, "heaviness" of feeling, vertigo, and pain in the head, back, and limbs, symptoms which appeared to be attributable, at least in part, to the hemorrhage, as I had attended her upon previous occasions when suffering with analogous symptoms resulting from profuse menstruation. July 22, 1 p.m., I was called to Mrs. W., and found her suffering with slight febrile excitement; pulse 90, full and strong; face flushed; pain in head, back and limbs. July 23, 9 a.m. Face greatly flushed and of scarlet hue; capillaries of the extremities and face and surface generally congested; patient greatly agitated and alarmed: says she has yellow fever, and will surely die. It was difficult, if not impossible, to calm her fears. Skin warm, but bathed in profuse perspiration; pulse 108, full and strong; great pain in back and head. 3:30 p.m., pulse 110; temperature 103.5 degrees; urine abundant, light yellow, slightly turbid from presence of vesical and vaginal mucus; a trace of albumen. Menstrual flow returned for an hour or two during the morning, but ceased again; capillaries of the surface intensely congested; tongue red at tip and edges, furred in center. July 24, 9 a.m., pulse 118, respiration 30, temperature 106.8 degrees; skin hot and dry. The fever rose in the evening; patient talked and muttered in her sleep, and frequently awoke suddenly with a start and cry; moans and sighs with every breath; is greatly agitated and alarmed; declares the case is utterly hopeless, and that her lower extremities feel as if they were paralyzed. Pain in head, back, and limbs intense; nausea constant and distressing, but no vomiting; heavy, disagreeable odor emit-

<sup>47</sup> Yellow Fever in Memphis in 1873, by R. W. Mitchell, of Memphis Tenn., Richmond and Louisville Medical Journal May, 1874.

<sup>48</sup> Bedside Notes on the Pulse, Temperature and Urine, in cases of Yellow Fever observed at Pensacola Navy Yard, in the fall of 1874, New Orleans Medical and Surgical Journal, May 1875, p. 779.

ted by the body, as in yellow fever; great congestion of capillaries; face and hands of a scarlet hue; an eruption has appeared upon the forehead; the surface of the face, trunk, and extremities is as highly injected and as red as in scarlet fever or measles, but the brilliant redness is more uniformly diffused over the surface than in either of these diseases. Urine abundant; light-yellow color; specific gravity 1020; contains a small amount of albumen, with detached cells from the tubuli uriniferi and yellow granular casts, together with vesical and vaginal epithelium. Upon standing, the urine let fall a moderate deposit of urates of ammonia and soda, mingled with the cells and casts. 3 P.M., pulse 108, respiration 36, temperature 106.3 degrees; skin hot and dry; face and surface generally of a deep scarlet hue; pressure drives out the blood from the capillaries and leaves a white spot, into which the blood slowly returns. Tongue coated in center, with yellow fur and red at tip and edges; swollen, with margins indented by the teeth; moist and soft. Nausea, depression, fear of death, and bad odor from the body unchanged. 9 o'clock P.M., pulse 112, temperature 106.2 degrees, respiration 38; moans and sighs with every breath; when spoken to answers rationally, but often slumbers, starts, and jumps in a delirious, nervous manner; odor from the body heavy and offensive.

July 25 10 A.M., condition unchanged; pulse 118; full and strong; respiration 36; temperature 108 degrees. The delirium and restlessness of the patient prevented thermometer being held well in the axilla; the actual temperature was therefore somewhat above 108 degrees, and probably reached from 110 degrees to 113 degrees in the cavities of the heart. Conjunctivae congested; gums red and spongy; odor of body very offensive; surface of face, trunk, and extremities greatly congested and of a brilliant scarlet hue; forehead covered with a distinct papular eruption. Urine light colored; specific gravity 1020; contains albumen in considerable amount, numerous granular casts of tubuli uriniferi, kidney cells, granular yellow albuminoid matters, and amorphous deposits of urates of ammonia and soda. Two hours after I was summoned to the bedside of the patient, and found her in *articulo mortis*; pupils contracted; spasmodic respiration, with death rattle in throat. I was informed that she had started suddenly in a disturbed sleep, made several ineffectual efforts to vomit, and passed immediately into this state. She was unable to swallow. Sinapisms were freely applied, but without effect.

The treatment of this case will be briefly mentioned, although we are not now engaged with this subject. The bowels were first opened with a saline cathartic, followed by quinin. Rest was then promoted by Dover's powder. The bowels were afterward kept open by means of enema. The diet was light but nutritious, and administered in small quantities at regular intervals; the action of the kidneys was promoted by the use of gentle diuretics, as orange-leaf tea and water charged with carbonic-acid gas. Quinin aggravated the delirium, and was abandoned at once. Alcoholic stimulants were found in like manner to aggravate the pain in the head, the nervous excitement, and delirium. Cold wet cloths were applied to the head, and the surface bathed with tincture of camphor and water.

In the last moments of life the scarlet flush of the surface gradually faded, and at the moment of death, which occurred at 1 P.M., the surface presented a yellow jaundiced hue; after death, body mottled; decomposition rapid. I attributed the death of this patient to the high degree of heat and the consequent disorganization of the blood and derangement of the nervous and muscular forces consequent upon the action of the febrile poison.

(To be continued.)

**Two Hundred Years' Theses in Paris.**—The number of theses for Doctor of Medicine defended before the Paris Faculty of Medicine from Dec. 18, 1794, to July 31, 1894 is 28,793; to these must be added 793 theses for "agregation," and 220 theses for professional honors, or a total of 29,806. The theses for "agregation" were in vogue for sixty years, from 1825 to 1886; those for professors about half that period.

## HOSPITALS FOR THE INSANE—THEIR SCOPE AND DESIGN.

BY EDWARD F. WELLS, M.D.

CHICAGO.

(Continued from page 41.)

### THE INSTITUTION.

**Capacity.**—The first questions to be asked in designing an institution for the insane is, What shall be its initial, and what its ultimate capacity? If these are to be the same it may be constructed upon rigid lines; if both are known only a limited degree of flexibility of design is necessary; but if, as is usually the case, the initial capacity is known, while the ultimate capacity is a decidedly unknown quantity, then the design should be so elastic that future extensions may be economically made, to any reasonable extent, without marring the symmetry or incurring any loss of balance. The truth of this proposition has been so often demonstrated that it should not only be frankly acknowledged, but heeded as well. Without going into any argument upon the subject, we should also acknowledge the fact that the irresistible tendency of the times is toward large institutions. The day of small State insane hospitals has long gone by, never to return—they offer no advantages and can not be afforded.

The question of capacity, initial and ultimate, should receive careful consideration in connection with the proposed new hospital for the insane in Illinois. It is clear that the initial capacity should provide for present needs, plus the probable increment during the period of construction, and the subject of present requirements will first demand attention.

There were, in 1880, in Illinois, 5,121 insane persons. In 1890 there were 6,638 insane, an increase equal to about 3 per cent. per annum. A continuance of this rate to the present time would indicate that there are now 7,534 insane persons in the State. Dr. Bettman, President of the Board of State Charities, estimates the number at 7,000. If the increment continued at the same rate during the construction period of a State hospital—estimated at two years—the number would be 7,932.

The comfortable capacity of the four State, and one large county, hospitals, together with the number of inmates now present, and with the overcrowding, as represented by the excess, is shown below:—

Hospital.	Capacity.	Inmates		Excess.	Deficit.
		Nov. 19, 1894.			
Kankakee.	2,000	2,090	90		
Jacksonville	1,200	1,222	22		
Elgin . . .	1,100	1,115	15		
Anna . . .	946	853		93	
Dunning . .	900	1,067	167		
Totals . . .	6,146	6,347	294	93	Corrected excess 201.

In 1892 there were in the county almshouses of the State—outside of Cook County—848 insane persons, distributed as follows:—

In the counties composing the Central Hospital District, 425; Northern, 167; Eastern, 158, and Southern, 98.

That these numbers have not decreased since that date is made clear by the investigations of Dr. J. F. McKenzie, Superintendent of the Central Hospital, who writes me as follows:—

"In the thirty-three counties composing our Lunacy District there are something over five hundred insane persons confined in poorhouses and jails. This fact I learned by sending a circular letter to the county clerks of the different counties."

It is quite probable that a canvass of the counties of the other hospital districts would disclose a corresponding increase in the unprovided-for insane.

Taking, then, the 848 insane in the almshouses, plus the probable increase of 144 and the hospital excess of 201, and we have a total of 1,193 insane persons in Illinois who urgently need hospital care at the hands of the State. The number will have considerably increased before the end of the building period.

Taking all these, and other facts into consideration, it is a reasonable opinion that the proposed new hospital should have an initial capacity for, at least, 1,200 patients, and that the growing demands of the State will require an ultimate capacity of, certainly, more than two thousand. These figures, instead of appalling our authorities should lead, instead, to careful consideration and judicious action.

*Location.*—It will have been noticed that the Southern Hospital has a capacity for 946, with only 853 inmates. It can accommodate 93 more than it does, and this is nearly equal to the number of the insane in the almshouses of the Southern District in 1892—98, or the probable present number, 114. The slight excess indicated could probably be best provided for by transferring the twenty-six insane of Clark County to the Eastern District. The almshouse contingent and hospital excess—dividing that of Cook County as provided by law—of the other districts would be about as follows:—Central, 522; Northern, 266; Eastern, 412; total, 1,200. A glance at the map, with due consideration of the present hospital districts, distribution of population, lines of transportation, etc., will show that the proposed new hospital should be given a district composed of the northern counties of the present Central District; the northwestern counties of the Eastern District, and the western counties of the Northern District.

The hospital should be centrally located and be conveniently accessible to all parts of the district it is intended to serve. It should be near some town or city of moderate size. The water supply should be of good quality and practically inexhaustible. Facilities for drainage should be perfect. Proximity to a cheap fuel supply and adequate railroad facilities are very important. These are of such vital importance that no site should be even considered which does not fulfill, absolutely, the first four requirements, and meets, fairly, the last. There are many other circumstances which will recommend one site above another, but these can not be considered.

*Water Supply and Drainage.*—In the matter of water supply the history of so many public institutions has been unfortunate that I feel the subject worthy of special mention and emphasis. As stated above, the water supply should be inexhaustible and the drainage perfect. The water supply plant should be designed for furnishing water at the minimum rate of 100 to 300 gallons per patient daily, and the system of drainage should easily dispose of the resulting effluent. Furthermore, inasmuch as the history of our State institutions show that they almost inevitably undergo enlargement, the mains for water and the trunk lines of sewer should, from the first, have a capacity of, at least, double that of the initial capacity. To meet the contingencies of possible accidents, two pumps should be provided.

*Design.*—Within a period of time easily compassed by the memories of persons yet living, three distinct systems of insane hospital construction have, in turn, found favor at the hands of superintendents and building commissioners, viz., the corridor, the cottage and the detached pavilion. The long gloomy corridor; the heavy-laden atmosphere, and the constantly

occupied ward have condemned the Kirkbride plan. The great cost of construction, and of maintenance, together with the impossibility of exercising any efficient supervision have made the cottage hospital unsatisfactory. The objections urged against the cottage system apply to the detached pavilion. The last two are free, in principle, from the radical and inherent sanitary defects of the first named.

Progressive managers of hospitals for the insane, in common with other enlightened directors of public economic affairs, have been, and always will be, eager to adopt that which all the world is seeking—the “something better”—and to the credit of these managers it may be said that there have been very few examples of retrograde movement in the construction of American institutions of this class.

Although not often formulated there can be no difference of opinion as to the fundamental requirements for the modern State institution for the insane. It must be healthful; it must conduce to the curability of insanity; it must afford facilities for minute classification; it must protect patients from injury; it must protect attendants from unjust accusations; it must permit efficient supervision by day and by night; it must be susceptible of convenient administration; it must be of economical construction; and, finally, it must favor economical maintenance. These requirements are not of an extraordinary nature—on the contrary, they are essentially commonplace, and common-sense—and they may be had in combination without sacrificing in any degree their individual excellence. Certainly, every new hospital should demand and receive the highest obtainable excellence in each and every one of these particulars.

*Facilities for Supervision.*—The wards should be so arranged as to permit efficient supervision, without increasing the cost. A closer system of supervision has always been desired by hospital managers and various expedients have been resorted to in the endeavor to improve upon ordinary methods. Thus there has long been employed at Norristown, near Philadelphia, a system of supervision by an inspector, who occupies a small chamber between two wards, elevated above the second floor. From this chamber the occupant commands a view, directly, of the two upper wards, and, by means of a tube and an arrangement of mirrors, of the two lower wards—in all, four wards. Of this system the Committee on Lunacy of Pennsylvania have to say in their report for 1891:—

“With the added experience and observation of another year your committee are firmly convinced that the present method . . . of supervising the duties of those who daily attend the inmates should be improved. The so-called inspectory system established by the superintendent of the male department of the Norristown Hospital, whereby inspectors control a view of the wards and occupants at all times, has continued in successful operation for several years past. . . . Your committee have been watching with interest the practical working of this system and further observation of the results, as compared with the usual methods of supervising attendants on duty, has led us to a favorable opinion of the inspectory system and, we recommend to the earnest consideration of the trustees and superintendents of other hospitals this, or some other plan for the better protection of the patients from violence, injury, or any dangerous coercion, and the attendants from groundless accusations.”

The Norristown system may be extended and simplified by centrally locating the supervisor's office, with respect to a group of four or eight wards, and placing it about four feet below the second floor so that a person occupying it may have a view of all the

wards on both floors. This room, being open to view and occupied by an ordinary officer changes the system from one of espionage to one of close supervision. However, the system is so elastic that any degree of oversight—from the closest surveillance to none—may be had at will.

Insane inmates of hospitals have their comfort and safety jeopardized at the hands of themselves, their fellows and their attendants. These dangers become greater in proportion to the distance the patients are removed from official supervision and control. The plans under which institutions for the insane are usually constructed remove a large proportion of the inmates—and often those who particularly require close surveillance—far from the seat of official authority and necessarily prevents that careful supervision which their interests demand. Under the modification proposed, the officers in authority are centrally located and have at all times—day and night—opportunity to see every ward and occupant and exercise a close, constant and immediate supervision over attendants and patients, guarding the latter and detecting negligence, unkindness and cruelty upon the part of the former, and protecting them from unjust charges.

*Radiate Pavilion Wards.*—To facilitate supervision and night attendance; to render administration more convenient, and to cheapen construction and maintenance, some of the buildings of such an institution may take the form of radiate pavilions.

The earliest examples of hospitals upon the radiate system, so far as my information extends, date back to, or beyond the twelfth century, when two were erected in France; one at Angers and the other at Chartres. During the war a very large hospital of this class, with a capacity of about thirty-two hundred, was operated at Washington, or Philadelphia, and was considered a model. The Marine Hospital at San Francisco, designed by Surgeon-General Hamilton, has some wards arranged in this manner. The model hospital exhibited at the World's Fair by the United States Government was upon this system. The Southern Indiana Hospital for Insane, at Evansville, is a notable example of this form of arrangement of wards for patients of the classes under consideration. Of the Evansville Hospital, the Indiana Board of State Charities have this to say—in advance of the opening of the institution—in their report for 1890:—

"The building is on what is known as the radiate plan, which is original as applied to hospitals for the insane. Its leading feature is that of bringing each section into equally close connection with the administration department, while still giving the advantages of light and air on all sides of every ward. It is expected, with reason, that this plan will be found to facilitate supervision and promote economy in the domestic arrangements, heating, water supply, etc."

After the hospital had been occupied for two years, the same Board says:—

"The internal affairs of the hospital have been remarkably free from disturbances of any kind. . . . It is possible that this condition of things, which must be recognized as more than ordinarily favorable, is partly due to the construction of the building. . . . It was designed, as is well known among persons who study hospital construction, by Dr. Rogers, and was the result of the careful study and experience of a very practical man. His opinion was that the radiate plan . . . would be moderate in first cost, economical in maintenance and particularly easy of supervision. The experience of the last year has certainly borne out all he claimed for it as far as maintenance and supervision go."

Later, and after four years' use of the hospital, Dr. Thomas, the medical superintendent, writes me as follows:—

"There are three things claimed for the radiate plan of hospital . . . 1, economy in construction; 2, economy in maintenance; 3, convenience of administration. The first claim has not been proven in the construction of this building, but in another building extravagance may be avoided. The second and third claims are absolutely proven to the most satisfactory degree. In my opinion the radiate plan has decided advantages over both the Kirkbride and the cottage plans."

*Attendants.*—The proportion of attendants to patients which is to be allowed will have an important bearing upon the number, size and arrangement of the wards. In a large State institution for the insane, where the interests of the tax-payers require the practice of as rigid economy as the proper care of the patients will permit, the wards might well vary in capacity from fifteen to thirty-two and be cared for by two attendants. To be sure, in practice, these numbers will vary according to circumstances. The practice in different hospitals may be inferred from the following table and statements:—

State.	Hospital.	Patients.	Attendants.	Proportion.
New York	Poughkeepsie	733	105	1 attendant to 7.0 patients.
"	Binghamton	1,136	157	" " 7.2 "
"	Middletown	709	80	" " 8.8 "
Indiana	Indianapolis	1,524	138	" " 11.0 "
"	Richmond	434	39	" " 11.1 "
"	Logansport	364	32	" " 11.3 "
Minnesota	Rochester	631	49	" " 13.0 "
Kansas	Osawatomie	519	39	" " 13.3 "
Ohio	Toledo	1,174	88	" " 13.3 "
"	Cleveland	807	52	" " 15.5 "
"	Athens	813	51	" " 16.0 "
"	Dayton	732	46	" " 16.0 "
"	Columbus	1,091	66	" " 16.5 "
Illinois	Anna	865	75	" " 11.4 "
"	Elgin	1,115	80	" " 13.9 "
"	Kankakee	2,090	160	" " 13.0 "
"	Jacksonville	1,222	80	" " 15.3 "
Totals and averages		15,958	1,317	1 " 12.2 "

At Dayton there are twenty wards with an average capacity of over thirty-six patients. Sixteen of these have two attendants each, and four,—the sick and violent wards on either side—have three each. At Logansport there are fourteen wards with an average capacity of twenty-six patients. Ten of these have two attendants each, and four have three each. At Richmond there are nineteen wards, ranging in capacity from ten to thirty, with two attendants to each ward, except one ward, which has three. At Jacksonville there are thirty-six wards, with two attendants to each, except four disturbed wards on which three attendants are employed. At Elgin there are two attendants to each ward, except on five, where there are three each. At Anna, two wards have one attendant each; twelve wards two attendants each; nine wards three attendants each, and four wards four attendants each. At Kankakee four wards have one attendant each; fourteen wards two attendants each; six wards three attendants each; seven wards four attendants each; two wards five attendants each; five wards six attendants each; one ward has seven attendants, and one ward has nine attendants.

*Night Attendance and Night Supervision.*—The attendance of insane patients at night—nursing the sick; attending to the wants of the well; soothing the excited; reassuring the fearful; caring for the filthy—and the supervision of night attendance, is a subject of prime importance. The prevailing practice varies in different institutions, but that much is left to be desired in this particular is almost universally admitted.

In Massachusetts, "at Westborough Hospital and the asylum wards of the State Farm every patient is seen each hour during the night. . . . Danvers Hospital has some large associate dormitories which have special night attendants; and these, together with the suicidal wards and infirmaries, make ten wards at the hospital having special night nurses—the largest number of any hospital in the State. . . . In some institutions many patients are not seen from the time they are locked in their rooms at night until they are awakened in the morning. A homicide at one hospital has illustrated the danger of confining two patients in one room; and there is but one hospital in the State where this is not done.

Taunton Hospital alone, under such circumstances leaves the door unlocked and wide open. The State Almshouse has in its asylum wards some rooms in which two patients are confined at night, but hopes to soon do away with this practice."

The practice in New York is as follows:—At Utica with 786 patients, 11 night attendants are employed. On the male side three wards—the suicidal, the filthy and the epileptic—each have one night attendant. On the female side four wards are attended by four nurses. All the other patients are looked after by four perambulating attendants. At Poughkeepsie 733 patients are cared for at night by 16 attendants. On the male side, 380 patients, and on the female side, a small number, are constantly in sight. At Willard 2,055 patients are given 32 night attendants. In the infirmary group 180 males have 4 nurses and 260 females have 10 nurses. In the other groups nine wards have each a night attendant. The remainder are looked after by nine perambulating night attendants who make hourly visits. At Buffalo, with 509 patients, 9 night attendants, 7 of whom are assigned to single wards and 2 making regular rounds. At Binghamton the 1,136 patients have 23 night attendants—16 on wards and 7 making rounds. At St. Lawrence 227 patients had 4 night attendants—2 in each of the two occupied cottages.

In Ohio, at Columbus there are 6 night attendants to 1,091 patients; at Cleveland 4 to 807; at Athens 6 to 813; at Longview 8 to 880; at Dayton 4 to 732; and at Toledo 10 to 1,174 patients.

In Indiana, at Logansport there is one night attendant to each of the ten detached pavilions. At Richmond there is one night attendant to each of the twelve cottages.

In Illinois, the practice, as courteously reported to me by the superintendents of the respective hospitals, is as follows:—At Anna there are five general night watches making rounds. There are no regular night attendants on wards but they are especially detailed as required. Supervisors and medical officers are subject to call, but none are regularly on duty at night. Dr. Lence, the superintendent, would like to have a regular night attendant for all patients were it not for the expense. Dr. McKenzie, of Jacksonville, says:—"Six night watches make hourly rounds. . . . When we have a case of acute sickness we always detail two attendants to watch and if the case does not require special attention, the night watches give them attention every hour." Dr. Loewy, of Elgin, writes:—"We have . . . fourteen night attendants on the wards. . . . On the hospital wards the night attendants act as nurses. The night attendants are assigned wards in proportion to the character of the patients in those wards. On the hospital wards one night attendant remains constantly on duty, one also on the wards containing the disturbed and untidy patients. On the better wards two and three wards are assigned to the night attendant. The head night watchman and the head night watchwoman act as supervisors on their respective sides. No medical officer is on duty at night, although I must say I am strongly in favor of it. At this hospital I believe every patient has efficient night supervision. I increased the night service by adding eight attendants about one and a half years ago. All the doors of the patients' rooms are left open at night." Dr. Gapen, of Kankakee, reports:—"We have a regular night service, the night nurses numbering eighteen, ten being in the male wards and eight in the female wards. We also have two outside watchmen. The supervisors have no responsibilities at night except as they are called, but both they and the medical officers are subject to call at any time. I have been steadily increasing the night service, and would like to increase it considerably more, and would do so except for the expense. . . . I should like to have night service in every ward or cottage, which would mean the increase of this force from eighteen to about thirty."

The proportion of night attendants to patients in several institutions is shown in the following table:—

State.	Hospital.	Pati- ents.	Night Attendants.	Proportion.
Indiana . . .	Richmond . . .	434	12	1 night attendant to 36 patients.
" . . .	Logansport . . .	364	10	" " " 36 "
New York . . .	Rochester . . .	350	10	" " " 35 "
" . . .	St. Lawrence . . .	227	5	" " " 45 "
" . . .	Poughkeepsie . . .	733	16	" " " 46 "
" . . .	Binghamton . . .	1136	23	" " " 50 "
" . . .	Buffalo . . .	509	9	" " " 56 "
" . . .	Utica . . .	786	11	" " " 71 "
" . . .	Willard . . .	2055	32	" " " 64 "
Ohio . . .	Toledo . . .	1174	10	" " " 117 "
" . . .	Athens . . .	813	6	" " " 135 "
" . . .	Dayton . . .	732	4	" " " 183 "

State.	Hospital.	Pati- ents.	Night Attendants.	Proportion.
" . . .	Columbus . . .	1091	6	" " 185 "

**Classification.**—In considering the subject of classification of insane patients for institutional care, it should be remembered that a pathologic, and a working classification are not one and the same thing. In a good working system of classification for hospital care and treatment, the patients are assigned to those groups and wards in which they can be best observed, treated and cared for; where they are least irritated and where they are brought in contact with congenial associates. The system must be very elastic and its various subdivisions can not be rigidly limited or their characteristics clearly defined. These facts will account for the apparent looseness with which the skeleton scheme here suggested is outlined. It is believed, however, that it fairly represents the system adopted by the superintendents of those hospitals having facilities for such classification. It provides for an institution with a capacity for 1,200 patients, and suggestions are made as to the manner in which the future capacity may be increased to 1,580 or 2,500.

#### SYNOPSIS OF CLASSIFICATION.

##### Hospital Group, Males and Females.

Fe- male.	Male.	Ward.	Fe- male.	Male.	Pati- ents.
Ward 1	A	Reception. For recent admissions. . . . .	25	25	50
" 2	B	Observation. " suicidal and special cases. . . . .	25	25	50
" 3	C	Sick. . . . . " the sick, injured, etc. . . . .	20	20	40
" 4	D	Infirmary. . . . . " infirm and special cases. . . . .	20	20	40
" 5	E	Untidy . . . . . " untidy and filthy. . . . .	15	15	30
" 6	F	Violent . . . . . " violent and disturbed. . . . .	15	15	30
" 6	6		120	120	240
Convalescent Group, Males and Females.					
" 9	I	Convalescent. For convalescents, etc. . . . .	30	30	60
" 10	J	Quiet. . . . . " quiet and refined cases. . . . .	30	30	60
" 11	K	Mild. . . . . " mild cases. . . . .	30	30	60
" 12	L	Mild & quiet. . . . . " and quiet cases. . . . .	30	30	60
" 4	4		120	120	240

##### GENERAL WARDS GROUPS.

General Wards Group, No. 1.			General Wards Group, No. 2.		
Females.			Males.		
Ward 17.	26 patients.	For quiet workers. . . . .	Ward Q.	26 patients.	
" 18.	26	" " workers. . . . .	" R.	26	
" 19.	32	" " quiet epileptics, etc. . . . .	" S.	32	
" 20.	32	" " workers, etc. . . . .	" T.	32	
" 21.	32	" " restless epileptics, etc.. . . . .	" U.	32	
" 22.	32	" " patients. . . . .	" V.	32	
" 23.	32	" " quiet demented, etc. . . . .	" W.	32	
" 24.	32	" " restless . . . . .	" X.	32	
" 25.	32	" " advanced . . . . .	" Y.	32	
" 26.	32	" " dangerous patients, etc. . . . .	" Z.	32	
" 27.	26	" " untidy patients, etc. . . . .	" AA.	26	
" 28.	26	" " disturbed patients. . . . .	" BB.	26	
" 12	360	"	" 12	360	"

##### GROUP CLASSIFICATION AND CAPACITY.

Hospital Group. . . . .	120 females.	120 males.	240 patients.
Convalescent Group. . . . .	120	120	240
General Wards Group, No. 1. . . . .	360	"	360
General Wards Group, No. 2. . . . .	"	360	360
	600	600	1200

**Additional Capacity.**—The wards in the various groups can be so arranged that additional wards may be erected, without disturbing those completed, as follows:—

	Female Wards.	Pati- ents.	Male Wards.	Pati- ents.	Total Patients.
Hospital Group. . . . .	2	30	2	30	60
Convalescent Group. . . . .	2	60	2	60	120
General Wards Group, No. 1. . . . .	4	100	"	"	100
General Wards Group, No. 2. . . . .	"	"	4	100	100
	8	190	8	190	380

These additions would raise the total hospital capacity to 1,580 patients. By duplicating the general

wards groups, as suggested, would increase the capacity to 2,300, and the same reduplication, with the additions, would give a capacity for 2,500 patients. In making these additions the proper hospital balance and symmetry is always preserved, and the classification will require only slight modification in detail.

**Organization.**—For an institution such as described, having a capacity for 1,200 patients, the following organization, for the immediate care of the insane, is proposed:—

	Hosp. G.	Conv. G.	G. W. G. No. 1.	G. W. G. No. 2.	Total.
Medical Superintendent.					1
Assistant Physician-in-charge . . . . .	1	1	1	1	4
Internes . . . . .	2		1	1	4
Apothecary and Pathologist . . . . .	1				1
Supervisors . . . . .	2		1	1	4
Attendants . . . . .	24	12	24	24	84
Night attendants . . . . .	6	2	4	4	16
Head attendants . . . . .		2			2
Totals . . . . .	36	17	31	31	116
Proportion of attendants to patients . . . . .					1 to 14.2
Proportion of night attendants to patients . . . . .					1 to 75

It is very important that the questions of total, group and ward capacities; of classification, and of organization, should be considered and provisionally decided upon before even preliminary studies are made for the plans for any proposed hospital. Plainly the buildings should be made to accommodate the inmates and to meet their various necessities and not *vice versa*.

**Plans.**—The details of plans for hospitals for the insane must vary within such wide limits to meet individual requirements that this subject can only be considered in a very general manner. However, there are some features of hospital construction which, if satisfactory results are to be obtained, must be considered as either essential or highly desirable. Some of these are briefly enumerated:—

1. Every institution erected for the care of the insane should be an improvement upon previous structures. It should retain the good features of the older ones and it should possess some new combinations or additions which will render it a decided advance in this field. No less ambitious object should be considered.

2. The ward should be considered the constructive unit, and each should be complete within itself and adapted to best meet the requirements of its inmates. It should be on one floor and should have a separate entrance.

3. The several rooms of the ward should be conveniently arranged and they should have an abundance of light and facilities for thorough ventilation.

4. The day rooms and dormitories should be entirely distinct and permit airing when not in use.

5. As far as practicable, the wards should be so arranged as to permit the supervision of several at the same time. The dormitories, especially, should be so arranged that a constant and immediate night service may be given several from a common center, thus promoting efficiency and economy.

6. Each of the groups or divisions should contain a sufficient number of wards to permit minute classification. Very large wards should be avoided.

7. Toilet and bath rooms should be separated from the living rooms by a ventilated lobby. All sewerage should be discharged directly outside the walls and there should be no basement pipes.

8. Facilities should be provided for quartering assistant physicians separately in the groups under their charge and in the immediate vicinity of their work. It is believed, and experience confirms the opinion, that by increasing the responsibilities of assistant medical officers, without diminishing the authority of the superintendent, that their interest will be enhanced and that a high grade of such officers may be obtained and retained, and that the superintendent, relieved of many petty cares and annoyances, will have more time to devote to those larger questions which should be his peculiar province.

9. The institution, as a whole and in its parts, should pre-

sent a pleasing and satisfactory appearance. This may be attained in an inexpensive manner. It should not be so plain as to be ugly, neither should it have, in any sense, a palatial appearance.

10. The construction must be good, safe and substantial, and the cost moderate.

**Cost.**—Institutions for the insane have varied, and will continue to vary remarkably in cost, depending largely upon circumstances already mentioned. As a matter of true economy and correct principle, flimsy, cheap and shoddy construction should be avoided; on the contrary it should be safe, plain, substantial and durable. Such construction is neither cheap nor expensive, and it is certainly not extravagant. The total and per capita cost of several hospitals is here given for comparison:—

State.	Hospital.	Capacity.	Total Cost.	Per Capita Cost.
New York . . . . .	Buffalo . . . . .	525	\$1,609,000	\$3,065
" . . . . .	Poughkeepsie . . . . .	830	2,039,000	2,456
Pennsylvania . . . . .	Danville . . . . .	750	1,593,000	2,122
Massachusetts . . . . .	Worcester . . . . .	650	1,299,000	2,000
" . . . . .	Danvers . . . . .	863	1,622,000	1,878
Pennsylvania . . . . .	Warren . . . . .	650	1,150,000	1,800
New York . . . . .	Middletown . . . . .	675	1,006,000	1,490
Pennsylvania . . . . .	Harrisburg . . . . .	650	921,000	1,400
Indiana . . . . .	Richmond . . . . .	434	547,000	1,260
" . . . . .	Evansville . . . . .	400	504,000	1,260
" . . . . .	Logansport . . . . .	364	435,000	1,195
Massachusetts . . . . .	Westborough . . . . .	405	472,000	1,165
New York . . . . .	Utica . . . . .	700	815,000	1,164
" . . . . .	St. Lawrence . . . . .	1,500	1,725,000	1,150
Indiana . . . . .	Indianapolis . . . . .	1,500	1,696,000	1,131
Illinois . . . . .	Elgin . . . . .	1,100	1,092,000	993
Illinois . . . . .	Anna . . . . .	946	1,054,000	1,110
Pennsylvania . . . . .	Dixmont . . . . .	525	690,000	1,066
Massachusetts . . . . .	Northampton . . . . .	470	490,000	923
Pennsylvania . . . . .	Norristown . . . . .	1,384	1,146,000	830
Illinois . . . . .	Kankakee . . . . .	2,000	1,656,000	828
" . . . . .	Jacksonville . . . . .	1,200	846,000	717
Massachusetts . . . . .	Taunton . . . . .	698	475,000	702
Totals and averages of 23 hospitals		19,219	\$24,882,000	\$1,295

In this connection, I wish to enter an emphatic protest against under-estimating the cost of adequately providing for the insane in public institutions. It has been proposed to establish complete institutions at a cost not to exceed \$200 per capita. Proper accommodations for these classes can not be furnished for any such sum, and calculations and expectations based upon such estimates are misleading and can only end in disappointment.

Insanity is undoubtedly the greatest calamity which can befall a human being. From the very nature of his condition he is usually helpless and powerless to do good and is a constant menace to the safety of himself and to others. From every point of view, therefore, he deserves, not only our sympathy, but our intelligent benevolence as well.

34 Washington Street.

## ALCOHOL AND ITS EFFECTS.

BY W. P. HOWLE, M.D.

ORAN, MO.

Alcohol pure in full strength is rarely used as an internal remedy. In the form of whisky, brandy or wine it is often used. In minute doses it *stimulates*; in large doses it intoxicates; in larger doses it may kill. Therefore its effects like the effects of anything else depend upon the quantity given, the conditions under which it is taken, etc. An ounce of alcohol in a pint of water or syrup makes a stimulant about the same strength as ordinary wine; a tablespoonful of this three times a day before meals improves the appetite and leaves no bad after effects. This quantity of alcohol would last a patient nine or ten days, and within a year thirty-six ounces or a little over three pints of alcohol would be used. This quantity would not harm the average adult.

Alcohol given in teaspoonful doses every hour or

two, soon makes a patient drunk, poisons him for the time being, just as large doses of opium or chloral would. Stop the dosing and nature restores by throwing off the alcohol. Alcohol is not deposited in the tissues as mercury is said to be. Confine the worst toper in the land for ten days and no trace of alcohol can be found in his tissues. The constant use of large doses of alcohol destroys the user. It kills one man by its effects on his stomach; another by its effects on the brain; in others the liver, kidneys or heart may be the organ to give way first. In other cases it seems to spend its force on the nervous system. It seems to act as a traumatic, wounding here and there as it passes through the system, setting up gastritis, pericarditis, meningitis, etc. Why it selects a certain organ in preference to another, I can not explain, but that it does so no one will deny. Gastritis caused by alcohol is as amenable to treatment as if caused by another agent; so with any ailment that alcohol may produce. Remove the cause and nature soon puts things in order. Looked upon as a traumatic, the effects of alcohol are more easily understood.

Some of our learned men, group the many deleterious effects of alcohol all under one head and call it alcoholism. This is a handy way of doing business, but very far from the truth. Alcohol may be doing great injury to a man's kidneys, while some other agent is ruining his stomach or brain. Removing the alcohol might relieve the kidney trouble, but would not stop the stomach or brain trouble. So in examining a drunkard, look for other causes of disease beside alcohol in making your diagnosis and treatment. A drunken man often lies out on the cold ground for hours and gets chilled. The effects of the chill may be quite different from those of an ordinary jag, hence a different diagnosis and treatment will be in order.

The victim of alcohol is exposed to many dangers outside of the effects of alcohol. He is careless, wounds himself, gets wounded, mixes with all classes of people and is therefore more exposed than the sober man. All these things must be considered in studying the effects of alcohol. In examining the brain of a drunkard can you say this or that change of structure was the result of alcohol, and ignore the fact that this man was a syphilitic, had had many hard blows on his head, had been in prison, had been beaten into insensibility a number of times, had been thrown off of horses, off of wagons, off of trains, down stairs, and many other things incident to drunkenness. All these things considered, are you positive that alcohol caused this or that lesion found at your *post-mortem*? Let us give the devil his due. It is natural when we wish to show up anything as bad, that we paint it in its worst colors. Alcohol is bad enough in its effects, but certainly is often accused of crimes to which it was only accessory.

I am on record as to how I feel about the user of alcohol, as to whether he is responsible for his acts, and will not discuss that phase of the question now. I see others engaged in this who are more competent. Alcohol has come to stay as a remedy; it is capable of much good or harm, according as it is rightly or wrongly used.

## SOCIETY PROCEEDINGS.

### Proceedings of the First Meeting of the American Academy of Railway Surgeons.

*Held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.*

*(Continued from page 989, Vol. XXIII.)*

On motion of DR. R. HARVEY REED, the Academy proceeded to the election or rejection of those present, to fellowship in the Academy.

On motion of DR. L. E. LEMEN, three negative votes were declared sufficient to debar an applicant for fellowship in the Academy.

The chair appointed Dr. L. E. Lemen, Denver, Colo.; Dr. F. H. Peck, Clinton, N. Y., tellers. The count of the ballots showed all present elected to charter fellowship with the exception of two.

[Owing to their mention in the preceding report, we omit the names of those who were present and who were elected to fellowship.—ED.]

Adjourned to meet at 2 P.M.

SECOND SESSION, FRIDAY, NOVEMBER 9, 2 P.M.

On motion of DR. F. H. PECK, Clinton, N. Y., the Academy proceeded to ballot on the applications of those gentlemen who were not present.

The tellers reported the following railway surgeons who had made formal written application, as having been elected to fellowship in the Academy:

Dr. David C. Ainey, Ass't Surgeon, D. L. & W. Railway, New Milford, Pa.

Dr. Wm. T. Bishop, Medical Examiner, Pennsylvania Railway, Harrisburg, Pa.

Dr. A. B. Brumbaugh, Surgeon, Pennsylvania Railway, Huntingdon, Pa.

Dr. W. H. Buechner, Surgeon, Erie Railway, Cleveland, Ohio.

Dr. J. F. Bancroft, Chief Surgeon, U. P. D. & G. Railway, Denver, Colo.

Dr. W. M. Bullard, Ass't Surgeon, Montana Central Railway, Helena, Mont.

Dr. G. P. Conn, Chief Surgeon, C. & M. Railway, Concord, N. H.

Dr. Geo. Chaffee, Surgeon, L. I. Railway, Brooklyn, N. Y.

Dr. M. Cavana, Surgeon, N. Y. P. & O. Railway, Oneida, N. Y.

Dr. Henry W. Coe, Surgeon, East Side Railway, Portland, Ore.

Dr. R. H. Cowan, Surgeon, N. & W. Railway, Radford, Va.

Dr. Leroy Dibble, Surgeon, C. R. I. & P. Railway, Kansas City, Mo.

Dr. Wm. T. Dalley, Ass't Surgeon, U. P. Railway, Salt Lake City, Utah.

Dr. W. L. Estes, Chief Surgeon, L. V. Railway, S. Bethlehem, Pa.

Dr. F. B. Eaton, Oculist, Oregon Railway and Navigation Co., Portland, Ore.

Dr. Spencer M. Free, Surgeon, B. R. & P. Railway, DuBois, Pa.

Dr. J. H. Ford, Chief Surgeon, Big Four Railway, Wabash, Ind.

Dr. Jno. F. Fulton, Surgeon, N. P. Railway, St. Paul, Minn.

Dr. L. C. Ford, Ass't Surgeon, U. P. Railway, Lima, Mont.

Dr. E. Griswold, Surgeon, Erie Railway, Sharon, Pa.

Dr. J. D. Griffith, Consulting Surgeon, K. C. F. S. & M. Railway, Kansas City, Mo.

Dr. R. P. R. Gordon, Surgeon, G. F. & C. Railway, Great Falls, Mont.

Dr. Jesse Hawes, Division Surgeon, U. P. D. & G. Railway, Greeley, Colo.

Dr. G.W. Hogeboom, Chief Surgeon, A. T. & S. F. Railway, Topeka, Kansas.

Dr. R. L. Harris, Chief Surgeon, S. & St. A. Railway, Oakland, Fla.

Dr. Lester Keller, Surgeon, C. & O. Railway, Ironton, Ohio.

Dr. Samuel Kennedy, Surgeon, Big Four Railway, Shelbyville, Ind.

Dr. Sherman Leech, Surgeon, B. & O. Railway, Mt. Sterling, Ohio.

Dr. N. Y. Leet, Chief Surgeon, D. L. & W. Railway, Scranton, Pa.

Dr. John McLean, Chief Surgeon, P. P. C. Co., Pullman, Ill.

\*Dr. E. A. McGannon, Surgeon, G. T. Railway, Brockville, Ont., Can.

Dr. S. L. McCurdy, Surgeon, P. C. C. & St. L. Railway, Pittsburg, Pa.

Dr. Truman W. Miller, Chief Surgeon, C. & G. T. Railway, Chicago, Ill.

Dr. Henry McHatton, Surgeon, Southern Railway Co., Macon, Ga.

Dr. W. D. Middleton, Chief Surgeon, C. R. I. & P. Railway, Davenport, Iowa.

Dr. K. A. J. Mackenzie, Chief Surgeon, O. R. & N. Co., Portland, Ore.

Dr. Wm. Mackie, Surgeon, C. M. & St. P. Railway, Milwaukee, Wis.

Dr. M. V. B. Newcomer, Surgeon, L. E. & W. Railway, Tipton, Ind.

Dr. R. Ortega, Chief Surgeon, M. I. R. R. C. P., Diaz, Mex.

Dr. J. F. Prichard, District Surgeon, C. & N. W. Railway, Manitowoc, Wis.

Dr. C. B. Powell, Surgeon, C. B. & Q. Railway, Albia, Iowa.

Dr. Geo. Ross, Chief Surgeon, Southern Railway Co., Richmond, Va.

Dr. J. F. Reger, Surgeon, B. & O. Railway, Littleton, W. Va.

Dr. F. A. Stillings, Chief Surgeon, C. & M. Railway, Concord, N. H.

Dr. C. M. Scott, Ass't Surgeon, U. P. Railway, Payette, Idaho.

Dr. S. S. Shield, Surgeon, N. Y. L. E. & W. Railway, Carbondale, Pa.

Dr. F. J. Schug, Surgeon, U. P. Railway, Tacoma, Wash.

Dr. A. N. Talley, Surgeon, C. N. & L. Railway, Columbia, S. C.

Dr. Wm. Thompson, Oculist, Pennsylvania Railway, Philadelphia, Pa.

Dr. B. H. Van Kirk, Surgeon, B. & O. Railway, West Newton, Pa.

Dr. Geo. M. Waters, Surgeon, Big Four Railway, Columbus, Ohio.

Dr. C. A. Wheaton, Chief Surgeon, St. P. & D. Railway, St. Paul, Minn.

Dr. G. A. Wall, Eye and Ear Surgeon, A. T. & S. F. Railway, Topeka, Kan.

Dr. W. H. Elliott, Chief Surgeon, Central Railway of Georgia, Savannah, Ga.

On motion of Dr. F. H. CALDWELL, the vote on Dr. W. W. Barnett was re-considered, and together with the application of Dr. Scott Helm, of Arizona, was referred to the Executive Board.

Dr. G. S. WORLEY, Chief Surgeon, J. St. A. & I. R. Railway, St. Augustine, Fla., read the following interesting paper on

#### TRAUMATIC ANEURYSM.

Under the name traumatic aneurysm, several distinct affections are usually classified. The so-called, diffuse traumatic aneurysm is, strictly speaking, not an aneurysm at all, being merely an accumulation of arterial blood diffused through the tissues of a part, and differing only from a case of ordinary wounded artery, by the absence of communica-

tion with the external air. Hence the term, traumatic diffuse aneurysm, applied to a wounded or ruptured vessel filling the whole neighborhood with almost limitless (not encapsulated blood) is evidently a misnomer, since some sort of sac is inherent to the idea of aneurysm and what has been so incorrectly named as above, is a wounded or ruptured artery with interstitial or subfascial hemorrhage. Since, however, the treatment of this affection is so nearly identical with that of other forms of traumatic aneurysm, it seems consistent to include it in any practical treatise upon this class of injuries.

The diagnosis of this condition can usually be made with tolerable facility. It is a subcutaneous, soft and fluctuating tumor, often of considerable size, containing extravasated blood, and appearing immediately, or very soon after the wounding of an artery. At first the skin covering is not affected, but in a few days it often becomes discolored with ecchymosis, caused by the infiltration of blood. If the opening in the artery be large and free, the tumor will usually exhibit pulsation, synchronous with the heart-beat accompanied by a thrilling, purring or jarring sensation, and frequently by a loud bruit. If the artery injured be a very small one, however, or if the opening in the arterial tunics be oblique or of a limited size, or obstructed, there will be no distinct pulsation or bruit. In such cases the tumor will be indolent and semi-fluctuating or will perhaps, exhibit an impulse which is communicated to it by the subjacent artery. Many cases are reported of diffused traumatic aneurysm in which there was neither pulsation, nor thrill, nor bruit.

The size of an aneurysm of this variety will naturally be determined in a great measure by its locality. For instance, in localities where the subcutaneous connective tissue is abundant and very loose, it may rapidly attain a considerable size, while in other localities, such as the palm of the hand or the bend of the elbow, in consequence of the strength and resistance of the fascia its growth is correspondingly restricted. When the blood is suddenly effused in great quantity, in a traumatic aneurysm of the axillary or femoral region, all the constitutional signs of hemorrhage—pallor, cold sweating, pulselessness and syncope—may arise; and sometimes, in such cases, death from anemic exhaustion, as well as from syncope, may ensue. Diffuse traumatic aneurysms require the same treatment as ordinary wounded arteries; Erichson wisely observes: "The treatment of these cases must be conducted on precisely the same plan as that of an injured artery communicating with an external wound; the only difference being that, in the case of the diffused traumatic aneurysm, the aperture in the artery opens into an extravasation of blood, instead of upon the surface. We must especially be upon our guard, not to be led away by the term 'aneurysm,' that has been applied to these cases, and not to treat such a condition, resulting from wound by the means that we employ with success in the management of that disease."

The safety of the patient, as a rule, depends on exposing the injured artery, and ligaturing it above and below the lesions. In deeply seated arteries this is not by any means an easy operation. In some cases, compression, with absolute quietude of the injured part, should be tried before resorting to ligation. When arteries are ruptured by fragments of bone in simple fractures of the leg or thigh, compression, digital or instrumental, continuous or intermittent, should be applied to the main trunk of the femoral artery. This together with the immobility of the injured limb and the moderate degree of pressure on the tumefaction which are furnished by the dressings of the fracture, has often proved much more successful than any other plan of treatment. So, also, in cases where the axillary artery is ruptured, for instance, in the act of reducing old dislocations of the shoulder joint, and a diffuse aneurysm forms in consequence thereof, compression should be applied to the subclavian artery over the first rib by means of a door key or other suitable instrument, while the arm is immovably fastened to the chest by a roller.

Should compression fail in either class of cases, deligation of the main artery will generally succeed; provided the arm be kept immovably fixed to the chest, or the leg be held motionless by the fracture dressings in the other. But, in cases where immobility of the injured part can not be secured, the wounded artery should be laid bare and ligated above and below the injury, with as little delay as possible.

When an aneurysm upon which this, which is called the "old operation" is about to be performed is so situated that the circulation in the main artery can not be controlled by digital compression, nor by tourniquet, nor by Esmarch's

\*Since deceased.

elastic ligature—as, for example, at the root of the neck—the operation should be begun by making a puncture just large enough to admit one or two fingers of the left hand, which should be quickly thrust into the swelling in such a manner as to plug up the orifice in the integuments; the finger or fingers should then search the bottom of the cavity to find the aperture in the wounded artery, covering the aperture with the finger to prevent any outflow of blood from it, while the tumor is freely laid open, the coagula removed, and the artery ligated on each side of the lesion, as was done by Dr. R. F. Weir, U. S. Army, during the late civil war.

There is another variety of traumatic aneurysm, the pathology of which is the same as that just described, but in which the extravasation is less extensive, and in which an adventitious sac has been formed by the agglutination of the surrounding areolar tissue. Most or all of the large aneurysms, however, could be included in this class, on account of the substitution of condensed connective tissue in the wall for the distended coat of the artery. The presence of a lining coat similar to the intima of the artery is not conclusive proof of the persistence of the latter; it may be entirely of a new formation. The common cause is a penetrating or punctured wound. It is said to be caused also, but much less frequently, by overstretching of the artery in the neighborhood of a joint and fracture. The continuity of the artery is usually not entirely destroyed, and while some of its blood escapes into the adjoining tissues, the remainder continues within it and is distributed through its branches. The effused blood is in part absorbed, and in part coagulates; and after a time a distinct sac is formed about it by condensation of the tissues, and it then differs in no essential way from the common encysted form of aneurysm. Its symptoms and its subsequent course are then the same, but during the stage of formation of the sac the condition presents symptoms of danger peculiar to itself. During the formative stage of the sac, also, the injury is peculiarly amenable to treatment by direct pressure, at the seat of injury; and often after the sac has formed, a cure may be effected by the same means. This is the one important practical point of difference between traumatic and spontaneous aneurysms.

There is another form of circumscribed traumatic aneurysm, which is called "hernial" and which results from the protrusion of the inner coats of the vessel through a wound or laceration of the outer tunics. This variety must be extremely rare; its existence, indeed, is doubted by many writers. The true circumscribed traumatic aneurysm results from a punctured wound of an artery—generally a large one—which has healed, the cicatrix afterward yielding, and a true sac being thus formed from the external coat of the vessel and its sheath. The treatment consists in compression, or in ligation of the artery at as short a distance as possible above the sac. Should, however, (in any of these forms of circumscribed traumatic aneurysm) the sac burst, allowing the aneurysm to become diffused, or should suppuration or gangrene appear imminent, the proper course would be to lay open the part freely and apply ligatures above and below, as in the case of the so-called diffused aneurysm already described.

Sometimes an artery and its contiguous vein are simultaneously wounded, and an abnormal communication between them established. This condition may assume two distinct forms, known respectively as aneurysmal varix, and varicose aneurysm. Aneurysmal varix consists in a direct communication between an artery and a vein. The arterial blood which is projected into the vein at each pulse-beat, dilates it more or less extensively, and causes its walls to thicken; the symptoms are the presence of a circumscribed irregular tumefaction, usually small and bluish in color formed by a dilated vein, having a peculiar tremulous motion and emitting a peculiar thrilling, hissing or buzzing sound, which arises from the passage of blood through a small aperture in the artery, into the dilated vein.

The tumor is usually accompanied by a varicose condition of the neighboring veins. It is soft and disappears upon direct pressure. It subsides when the limb is elevated so as to favor the return of venous blood toward the heart, and in the same way its pulsation is rendered less distinct. But when the limb hangs down, or pressure is applied to the vein on the cardiac side of the tumor, it enlarges and the pulsations are increased.

Compressing the vein on the distal side of the tumor does not lessen either its size or its pulsation. When, however, the artery is compressed on the cardiac side of the tumor, the pulsation immediately ceases, and it instantly returns on raising the compression.

Varicose aneurysm differs from an aneurysmal varix, in that the arterio-venous communication is indirect, through an interposed aneurysmal sac. Its symptoms are a combination of those of aneurysmal varix and of ordinary traumatic aneurysm; the tumor, as a rule, gradually enlarges and becomes more solid by the deposition of fibrin; there is a distinct impulse added to the jarring sensation of the aneurysmal varix; and there is an aneurysmal whirr super-added to the rasping sound heard in the former affection. The proper treatment of the affection, if the sac is enlarging, consists in laying open the tumor and tying the artery above and below; in doing this, however, it must be borne in mind that the first incision (which opens the dilated vein) merely exposes the external orifice of the sac, and that this must be laid open by a second incision, when the aperture of the artery will be found more deeply seated.

The question of tying both artery and vein with double ligatures, is one which should be decided by the surgeon according to the exigency of the case. Professor Ashurst, from whom I have borrowed these illustrations respecting the various forms of traumatic aneurysm and their appropriate treatment, has hardly done more than gather up into a whole, the generalizations of his leading scientific and practical contemporaries.

In the treatment of traumatic aneurysm, particularly the varieties demanding immediate operative interference, we have a superb illustration of the slang maxim that "nothing succeeds like success."

The indications for treatment and the methods applicable for each individual case must be determined by the surgeon in attendance having in view the recognized and established laws of surgery, possessing a thorough knowledge of the anatomy of the parts to be operated upon, their correlative nervous and vascular supply and the general surroundings of the patient; he should be able by proceeding cautiously, step by step, to adopt the methods most applicable to the case.

The judicious application of pressure to the site of the injury or to the main artery, which is often essential to the successful treatment of this class of injuries, will not infrequently tax the ingenuity of the surgeon to its utmost. There can be no specially devised paraphernalia such as tourniquets, compressors, clamps or bandages which will meet the requirements in all, or in any considerable number of cases on account of the difficulty in adjusting them properly, so as to control the circulation in the wounded vessel, and at the same time protect the collateral circulation and other important structures from injurious pressure.

The more we allow ourselves to depend upon what we consider a complete armamentarium of ingenious, complicated and, as a rule, costly appliances, the more certain are we to fail in the accomplishment of our designs. It is much easier to cut a curved line with a straight knife than a straight line with a curved knife. If the surgeon understands the exact condition with which he has to deal, his skill and tact should be equal to the emergency, and his success will often be a matter of surprise to himself and the profession over the wonderful and unexpected results accomplished with such clumsy and unscientific appliances. I do not mean by this to detract from the value of useful scientific instruments or appliances, or to disparage their use, for many of them are as indispensable to the surgeon, as the saw or square is to the carpenter, but the idea that a surgeon is incompetent to treat a complicated injury of this class, or any other class for that matter, simply because he is not in possession of some ingenious instrument or appliance devised by Professor so-and-so expressly for the purpose, is one of the gigantic errors and stumbling stones in the path of every would be successful surgeon.

The place for the armamentarium of the surgeon is in his head and not in his office or instrument case; more especially does this apply to the railway surgeon who, as a rule, has nothing but emergencies to deal with and where it is always the unexpected that happens.

The difficulty encountered by the surgeon in cutting down upon, and ligating a wounded artery in a case of diffuse traumatic aneurysm, where its continuity has been entirely destroyed, and where it is necessary to secure both ends of the vessel, or in cases of encysted aneurysm where it is necessary to ligate the artery both on the proximal and distal sides of the sac, and especially in cases of varicose aneurysm, where it may be necessary to tie both the artery and its contiguous or communicating vein separately, both above and below the tumor, are often very great, and must be overcome by the cool deliberate horse sense of the surgeon or his patient will surely suffer the consequences, likewise his own reputation.

I deem it unnecessary to add that in all cases where wounds are made for the purpose of ligating vessels, the strictest antiseptic precautions that are possible under the circumstances should be observed. The antiseptic catgut ligature or a catgut ligature supposed to be antiseptic, is generally used for tying the vessels, but I prefer a specially prepared silk ligature for the purpose, prepared in the following manner: I take a small hank of No. 1 or 2 braided silk, and immerse it for several hours in a solution containing two parts of pure carbolic acid, two parts salicylic acid and ten parts of white wax, keeping the solution in a melted state by heat. The silk is kept in this solution for five or six hours, when it becomes so thoroughly saturated with the wax that it will remain in the tissues for several days without absorbing moisture or causing irritation. Moreover, it is, I suppose, impervious to the various pathogenic germs, which are credited with being the cause of so much trouble in these cases.

It has at least the following advantages: It is easily applied and when tied with the ordinary reef knot it will not slip. It can remain for several days in the tissues without irritating them to any appreciable extent, and the artery can be more securely occluded by it than with any other substance with which I am acquainted, especially the deep arteries which are difficult to reach.

The wound of operation should be dressed antiseptically, and redressed as often as necessary, and allowed to heal by granulation; after the ligatures have become detached and the wound is in a healthy condition the granulating surfaces should be approximated by adhesive strips or other suitable means and encouraged to heal by direct union.

The complications usually encountered in the treatment of this class of injuries are those naturally incident to obstruction of the circulation. The all important indication in cases where the main artery and vein of a limb have been occluded by ligature or other cause is to protect and preserve the collateral circulation.

The simultaneous occlusion of the main artery and vein of a limb should not cause mortification, unless the collateral channels are also obstructed. These channels may be dangerously obstructed by pressure exerted upon them from careless bandaging, or by the position in which a limb may be placed, as well as by the compression which arises from edematous, inflammatory, and hemorrhagic swelling. The aponeurosis or fascia cause strangulation by acting as unyielding bands, and should be freely incised, when necessary, in order to relieve extreme tension and the consequent pressure occasioned thereby.

I will not tax your patience further by suggestions upon the operative technique of any of the varieties of traumatic aneurysm. The diversity of method among surgeons is as great almost as the number of surgeons in existence. The idea is to determine what to do, and the general rules relating to how it should be done, with special reference to the complications liable to ensue, and then do it in your own way.

I know it is often beneficial to compare methods and endeavor to eliminate what is unnecessary in technique, and reduce everything connected with operative work to the greatest possible simplicity, but the confusion which would inevitably result from any such comparison in this instance would be greater than the benefits achieved.

In the absence of Dr. N. Y. Leet, Chief Surgeon, D. L. & W. Railway, Scranton, Pa., who was to have opened the discussion, the paper was discussed as follows by the different Fellows of the Academy:

#### DISCUSSION.

DR. J. HOWARD WILLIAMS, of Macon, Ga.—My experience with traumatic aneurysm is rather limited. Most of my cases have been from gunshot wounds. I have never seen a case in railway injury, nor have I ever seen a traumatic aneurysm in the early stages; it has always been a circumscribed traumatic aneurysm. Most of them, as I say, were from gunshot wounds, but some of them in railroad work, however. The only thing I have ever been able to accomplish in the treatment of them was the ligation of the arteries supplying the aneurysm. Compression or any other method of treatment has not succeeded. I have tried introducing wire into the sac and the use of electricity, but the only thing that has ever succeeded with me has been ligating the arteries above the sac.

DR. C. D. EVANS, of Columbus, Neb.—While the paper is certainly a masterpiece in regard to traumatic aneurysm, there is one thing that has not been mentioned and that is the bloodless method of treating traumatic aneurysm. I had never thought of it until about three months ago, when I operated on a patient for traumatic aneurysm, and the absence of that point in the paper brings it very forcibly to my mind. A doctor from a neighboring town brought me a case of traumatic aneurysm. It was a very plain case and very easily diagnosed. The man's leg in the upper two-thirds from the knee down was very badly ecchymosed, and a large fluctuating tumor was noticeable about midway or a little below midway on the outer side of the leg. To make a long story short, I applied an elastic bandage above the knee, and controlled hemorrhage in that way, making the lower limb bloodless, which to a great many may not seem good surgery. I ligated the posterior tibial artery, and that was the end of it. The wound healed by first intention. I turned out all the clots of blood almost the size of a goose egg. I might add also in connection with this case of traumatic aneurysm, that the man was a brickmaker by trade and was wheeling heavy loads of brick. The history he gave of the injury was this: The rain was going to destroy the brick. Several of them were wheeling heavy loads of brick together, and another man ran against his leg with the wheel of his wheelbarrow, and having a very heavy load at the time, his muscles were very tense, and the wheel coming in contact with his leg caused the injury.

DR. JOHN E. OWENS, Chicago—I have not seen an aneurysm for a long time and I do considerable hospital practice. I can not account for it occurring in the practice of other men, and yet there is nothing special in my treatment that would prevent aneurysm. The last case of traumatic aneurysm that I have in mind was a miniature one resulting from fracture of the tibia, and there was a small pulsating tumor about the size of a filbert. I cut down upon the part and could not find anything to compress in the bone. Compression did not seem to have any effect, and the pulse was very easily observed. I cut down upon it expecting to find some vessel running into the bone around which I could place a ligature and cure it. I fished around for a long time, but could not find anything, and becoming somewhat discouraged I took a chisel and scooped everything out of the bone and cured it. I think we should use the elastic bandage in cases of traumatic aneurysm with some degree of circumspection. It is an obstructive disease of the circulation. I refer to aneurysm in which the circulation is more or less disturbed and mortification supervenes very frequently, not only after traumatic aneurysm, before any operation has been done, but even after some operation like ligation or pressure. If we look at the liability of a case that comes to us in our line of work, we can readily see that the elastic bandage is an element in the treatment of traumatic aneurysm which may give us some trouble. The elastic bandage may be stretched considerably, and I should feel a little uncomfortable if I used it for fear of causing mortification. I would be disposed, I think, speaking in a general way, without going into details, to adopt pressure in most cases, and if I did not get very satisfactory results, I should at once cut down upon the vessel where it is possible to do so, and tie above and below. I would feel better when I got home after having done this.

DR. REED, of Ohio—I am very glad to see that we have with us an eminent surgeon who has just arrived. I know that he is posted on aneurysm, and I would be glad to hear from him. I refer to Dr. Bevan, of Chicago.

DR. ARTHUR D. BEVAN, of Chicago—I, unfortunately, did not hear the paper, but simply had an opportunity of hearing the latter part of Dr. Owen's discussion. The paper, I

believe, dealt with traumatic aneurysm. I have had a very interesting case of this kind within the last few weeks which may be of interest to report. A boy of 20, received a stab wound at the apex of Scarpa's triangle. He was taken to the Cook County Hospital, and hemorrhage at the time was rather profuse. A dressing was applied which controlled the hemorrhage. The wound almost healed, and at the end of two weeks he was discharged from the hospital with a small suppurating sinus. At the end of three weeks, after the receipt of the wound, he was brought to my service at the Presbyterian Hospital with a swelling about the size of a small chicken egg over the seat of the original lesion. The signs of traumatic aneurysm were very marked. I put him under chloroform, and cut down upon the line of the mass, and I found this interesting condition: There was a stab wound anteriorly through both sides of the artery just at the apex of Scarpa's triangle. The wound of the anterior surface of the artery was about three-quarters of an inch in length, and the wound on the posterior surface, about a quarter of an inch in length. I opened up the entire field of the lesion, the aneurysmal sac which surrounded the artery and vein and deep fascia of the thigh. The blood was pumping through the artery, and it is really remarkable that the patient did not have more hemorrhage because the sac seemed to be in direct communication with the fistula, although filled up with fibrin. The saphenous nerve was to the outer side of the vessel and the femoral vein to the posterior side. The operation was that of ligation. The patient made a good recovery without any interference with the circulation of the limb. Although I did not hear the paper, I am rather inclined to think that the idea of treating traumatic aneurysm by pressure was advocated. Personally, I do not think of a case in which I would feel warranted in treating traumatic aneurysm by pressure unless at some inoperable point of the anatomy.

DR. W. H. BUECHNER, of Youngstown, Ohio—I think traumatic aneurysms in consequence of railway injuries are extremely rare. I have had a rather extensive railroad practice of twenty-seven years and have never met with one. As far as the treatment is concerned, I think the only rational treatment is to shut the vessel off. I have tried compression, electricity, etc., and I have never found that either of them amounted to much. I have always succeeded by tying the vessels. The largest traumatic aneurysm I ever saw was at Professor Volkman's surgical clinic in 1886. It was caused by a stab wound in the brachial artery. He tied the vessel on both sides, and I saw the man probably six weeks after with a perfectly useful arm, a good pulse and wrist.

DR. EVANS—I saw a case of traumatic aneurysm about twenty odd years ago. The young man was 28 years of age, of general good health, and fairly well nourished. He was swinging on a horizontal bar, and within a few hours an aneurysm of the upper third of the brachial artery presented itself. The case is hardly in line with the Doctor's paper, yet it was due to traumatic causes. The axillary artery was ligated at its upper third, and eight days afterwards secondary hemorrhage came on. The patient made a very nice recovery. I think the success of this case was due to an idea I got from an old physician who saw the case with me, and that was compression by a bandage over the first rib, keeping it there until the wound had entirely healed. I think largely the success of the secondary operation of ligation of the axillary artery in the upper third was due to that compression. It was not stiff enough to entirely close up the wound.

Another case: A brakeman who was thrown from a freight car received an injury about the fascia lata. There was evidently considerable effusion of blood underneath it, because the swelling of the part was as large as an

ordinary orange. I laid the parts thoroughly open, expecting to ligate some of the vessels, but in using hot water after the aneurysm was arrested, the wound closed up, and the patient made a good recovery.

In another case in which there was a stab wound of the subscapular artery, I laid the parts open extensively and ligated. Compression did no good. As to the use of the elastic bandage, I must say I feel some doubt as to the propriety of using it, especially when the blood supply is already interfered with. Much injury can come not only from what blood vessels remain intact, but also to the nerve tissue itself, and quite serious results might follow.

DR. SCOTT, of Temple, Texas—One or two thoughts come to me since this subject has been opened for discussion that I think might well be brought up. In regard to the treatment, we must say that it necessarily varies according to the location of the aneurysm. Compression may no doubt be very good in some instances, and in others it may be harmful. I hardly think of using compression in some cases, particularly elastic compression, such as mentioned. But there are certain localities where I am satisfied compression is very good, one in particular which the Doctor has mentioned in injury to the subscapular artery. It is hard for one to understand what is to be feared in opening an aneurysm in that location unless he has had previous experience. But to one who has opened an aneurysm, perhaps as large as the head in that locality and had the pleasure of hunting around and trying to find the bleeding vessel and some features connected with it, it naturally brings about dread. I would say that there are some cases, no doubt, that possibly can be controlled by compression, but I would not think of using it until after the blood clot had been removed. I have seen two cases of traumatic aneurysm in or about that locality. In one that I was called to see, torsion was used instead of ligation. In the other case, which I had a few months ago in Temple, I was uncertain as to whether to search for the vessel or not, and I concluded to simply make an opening, remove the blood clot, and if the bleeding were great, I would go for it. In some cases it is safer to depend upon compression, provided compression will do. I had some evidence of the location of the injury on account of the contusion of the skin. I was satisfied it would be much easier for the patient and less embarrassing for myself to use compression. This I did, and controlled the hemorrhage very nicely. But there are one or two points, I think, that should receive some attention. It seems to me that the uniform opinion expressed here is that when a vessel is exposed it should be tied both above and below the seat of injury and the wound closed up, and the aneurysmal tumor divided between the points of ligation. It may seem a little previous in suggesting under these circumstances, torsion. I would favor it for several reasons, and among them the principal one is this, that when we have large aneurysmal tumors there is abundant reason for absorption, and if any infection whatever takes place during the operation we are very liable to have serious trouble resulting. The doctor who read the paper on this subject suggested, I believe, that this particular line of injuries came under the head of emergency work, and if it is emergency work, then we are not usually properly prepared with our ligatures, that is, the average railway surgeon is not always prepared for such emergency work. He cannot always depend upon the ligatures he has, and under such circumstances it is much safer to resort to torsion. I desire to say that recently I conducted some experiments, the results of which I read before the Texas State Medical Association not long since and expected to have had them published in *The Railway Surgeon* before this, but the paper has not yet appeared. My experiments were conducted along the

line of torsion. I will mention one of them. The carotid artery of a dog was ligated, exposed, and a tube attached to it. The blood arose (in the dog's carotid artery) to about six feet in this case, and in another about five and one half feet. Then the tube was immediately removed, and about three inches of the artery were excised, the proximal end of the artery was twisted, then let go, and it failed to bleed. The tubing was then emptied and the blood vessel left attached to the tubing by a small canula. The tubing was filled with water, attached, a portion of the artery three inches long was twisted, and water allowed to flow into the vessel to see if it would cause the blood vessel to recoil or leak. The tubing was then doubled in length and filled with water rising to a height of eleven feet. This is not absolutely correct but approximately so. There was double the normal arterial pressure, the water was allowed to flow into this excised and twisted artery, and it did not cause it to open or recoil, demonstrating that a twisted blood vessel, when properly done, would resist double the normal blood pressure. That experiment was carried out in several ways. Many other experiments were done, and in connection with them, the abdominal aorta was exposed and excised, caught between two forceps and each end excised, when it remained pulsating for quite awhile after the dog was dead. I mention this to show that torsion will resist double the normal blood pressure, and we can depend upon it in these cases of aneurysmal tumors more certainly than we can ligation with silk, silkworm gut, chromicized catgut, or anything else. I have so far never heard of secondary hemorrhage from it, if it has been properly applied. It is not rare to find secondary hemorrhages from various causes where ligatures are applied.

DR. HARNON, of Waverly, New York—I have very little to say on this subject. I have seen very little of traumatic aneurysm in railway practice. I remember a serious case in hospital practice twenty-five years ago, where it wound up with the death of the patient. The case did not occur in my practice. It may appear somewhat sensational to you, but I believe the day will come when aneurysm will be successfully treated. When a blood vessel has been severed or nearly so, so that compression may not destroy the circulation, then I believe as a preventive of amputation that the aneurysm may be removed and the blood vessel restored by dissecting it out, perhaps stretching it somewhat which you know it will bear, and restoring its continuity by placing some tube within its walls carrying on circulation. All that remains is to make that experiment. It has been tried and has been successful, temporarily restoring the circulation in the limb by placing a tube there which would absorb without any harm being done. I believe in this direction lies a successful remedy for traumatic aneurysm.

DR. COLE, of Helena, Montana—The author of the paper drew a graphic picture between varicose aneurysms and aneurysmal varix. I simply wish to dwell upon one or two points. The author spoke of the uniform constant thickening of the walls of the veins in those cases. Where that is the rule, I think he will agree with me it is not invariably so, and sometimes they burst through. In aneurysmal varix the wall of the veins is thin and leads to disastrous results. About three weeks ago a case was brought to my hospital in which there had been a dislocation of the joint. My assistant reduced it and overlooked a lateral dislocation of the radius. The case occurred about a month prior to my seeing it, and in attempting to replace the dislocation I succeeded in injuring the artery and produced a small traumatic aneurysm which yielded satisfactorily to pressure. I do not believe any more in the pressure treatment as a rule, than those who have expressed themselves here to-day, yet I am satisfied in emergency work we cannot be guided by any

ironclad rules. We cannot lay down a rule that will be invariably followed with success. As a rule, the safer plan is ligation of the artery, not necessarily ligation of it on each side of the injury. I think that operation and the excision of the vessel between the ligatures should be done with reference to the size of the vessel and the location of the injury. I think the writer perhaps was a little misquoted by some one in saying that he invariably recommended ligation of both sides. I do not think that statement was made in the paper, nor do I suppose any one would advocate that as an invariable rule.

DR. REED, of Columbus, Ohio—I have been highly entertained by the discussion of this excellent paper. It is a subject which, although not of unusual occurrence in railway surgery, is sufficiently frequent to give the surgeon considerable annoyance when it does occur. It is this class of cases that will cause you as much annoyance as any other class you may meet; at the same time, in the treatment of traumatic aneurysms we should be governed by two principal points: 1, the treatment in the primary stage; and 2, the treatment in the subsequent stage, what we might term the secondary stage of old traumatic aneurysm. In the treatment of the primary condition, such as was alluded to by Professor Bevan, we can readily understand that it would be necessary as a rule to apply a ligature, torsion, or some method which would get rid of a bleeding aneurysm, the sac of which was made up of the connective tissue, and which would be dangerous to allow to remain. I have in mind at present a case similar in character to the one reported by Professor Bevan, in which an injury occurred to the femoral artery, penetrating it from side to side, and also penetrating the vein, producing a punctured wound of both the femoral artery and femoral vein. The party was a male clerk on one of the roads running out of Columbus. The attending physician thought it was useless to do anything, and allowed the man to go without treatment, excepting to put him on his back and keep him as comfortable as possible. To his astonishment he got well with an aneurysm; in fact, he not only got well but lived and worked for fourteen years, with this aneurysm. It was situated about the region of Scarpa's triangle. Subsequently the man was taken sick and I was called to see him and observed this aneurysm. The man subsequently died of another sickness, which enabled us to make a *post-mortem* examination of the aneurysm which was the result of traumatism, and upon examining this we found that the artery had closed in this manner. We will suppose a gunshot wound or its equivalent passing through the artery from side to side, but immediately around the artery, the connective tissue formed an aneurysmal sac, just as described by Dr. Bevan, until it was perhaps as large as an orange. This sac was strong enough to hold the blood and become a part, as it were, of the walls of the artery. On the other side was a similar sac which was adherent to the vein. The connective tissue was pushed out by the force of the blood against the hole made in the vein and artery and plugged both. There was adhesion of the connective tissue to the vein which formed a sac around the artery, making a complete aneurysmal sac, and at the same time closing up the wound so there would be no escape of blood. This sac thickened and became so strong as to enable the man to go on with his work without difficulty, so far as the aneurysm was concerned.

There is one method of treatment that has not been touched upon here this afternoon, and that is the Macewan needle operation which, I think, in aneurysms of this character would be advisable. I do not think the needle operation, however, would be advisable in acute aneurysm, or in aneurysm due to a recent injury.

I do not think the wire operation of Professor Ransohoff, as advocated by him before the AMERICAN MEDICAL ASSOCIATION, would be of service. I think that method of treatment is absolutely dangerous on account of the liability to the formation of clots and emboli. I simply bring up these points as being important, and which have escaped attention, in speaking of the treatment of aneurysm, and more particularly the needle operation. I have seen Professor Senn use it successfully in the Presbyterian Hospital, of this city in several cases.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, JANUARY 19, 1895.

FOOD AND DRUG ADULTERATION.

The earliest investigations into this subject conducted under National auspices were those made by PROFESSORS DIEHL and KEDZIE and DR. SMART of the Army, for the late NATIONAL BOARD OF HEALTH. The field of operations of the last named investigator was quite extensive and was intended to develop the amount and character of food adulteration in this country, with a view of determining whether federal legislation was needful for its suppression. The conclusions arrived at were that few of the adulterations then practiced were of a deleterious character, that they affected the pocket of the individual rather than his health, and that the question of legislation should therefore be viewed from the commercial rather than the sanitary standpoint.

Since then the Department of Agriculture has taken up the subject and published several reports, one of which, Bulletin No. 41, "On the Extent and Character of Food and Drug Adulteration, by ALEX. J. WEDDERBURN, Special Agent," is now before us. Earlier bulletins, particularly Nos. 13, 25 and 32, were valuable as giving the methods and results of analyses; but the benefit to be derived from the present issue is not so evident, as it consists mainly of communications from persons assumed from their position or occupation to have knowledge of the subject. PROFESSOR DIEHL in his report to the late NATIONAL BOARD OF HEALTH characterized communications of this kind as productive of no satisfactory result, the information furnished being too vague and general in its character. That he was correct in this estimate seems proved by the extracts published in Bulletin 41. Their general tenor goes no further

than such assertions as, "I am sure," "I have no doubt," "it is my opinion," "I am credibly informed," or "there is no question," "that food adulteration is largely on the increase," etc.; although some acknowledge lack of specifications to sustain the charge: "While we have no evidence that would be worth anything to you, we do know that there is scarcely an article of food offered by the grocers throughout the country that is not adulterated." One reporter asserts that, "some of our flour is adulterated more or less with a certain kind of earth that comes from the South;" and in a list of the ordinary sophistications of foods and drugs arranged alphabetically by the compiler, we find, p. 51, under the title *Eggs*: "The yolks of eggs are now largely imitated, and it is stated that the whole egg is now successfully duplicated as a result of scientific genius." This recalls the sensational newspaper articles of HASSALL'S time which led the English cockney to look askance on milk as a possible emulsion of sheep's brains, prepared by the depraved and conscienceless inhabitants of the rural districts. Even some parts of MR. WEDDERBURN'S report are open to a similar criticism. He holds that the extent of adulteration of food and drugs is 15 per cent., although only 2 per cent. is of a character injurious to health. The cost of furnishing food, drink and drugs to 65,000,000 people, at an average weekly rate of \$2 per head, amounts to \$6,760,000,000, and 2 per cent. of this, or \$135,200,000 is "the annual amount paid by the American people for having their lives taken or their health injured." PROFESSOR WILEY, the Chief of the Division of Chemistry, in a prefatory note, disclaims responsibility for the opinions of the correspondents cited in the published selections, as well as for some of the conclusions reached by the compiler; but in looking over the pages of this Bulletin the question constantly in mind is, Why should such statements have been published by a scientific bureau of a Governmental Department? A National food and drug law is sorely needed from the commercial point of view, for the protection of the individual as well as for that of legitimate industry and interstate and foreign commerce, and in some instances it may be urged from the sanitary standpoint; but evidence of the kind now presented is not likely to have much weight in effecting its passage.

*Let there be created a Department of Public Health!*

THE WORK OF THE SECTIONS.

At the risk of being somewhat tiresome, we once more venture to invite the attention of the members of the ASSOCIATION to the great advantage of concise writing, and short papers. The short paper is invariably read by the majority of the readers, the long paper is retained and perhaps laid on the shelf. The brief paper from which every superfluous word

has been carefully pruned, is more valuable than a paper involved in expression, and loaded with adjectives.

We have no quarrel with the complimentary adjective on its own account, nor with tropes and metaphor, but they have their place. That place is not found within the limits of a scientific paper read at a medical society for instruction.

We have once before mentioned the admirable work of the Surgical Section last year at San Francisco, but it will do no harm to again mention the fact that DR. ROBERTS, the Chairman, placed a time limit on the papers to be read at the meeting, and it was so announced in his circular calling for articles. The result was an admirable series of papers, fresh and bright with the individual thoughts of the authors themselves. In the average society paper, unless specially included in the historical class, there is no need of embodying in it, the entire history of the subject. The writing is not intended for the encyclopedia, but for current medical literature, and it will be remembered, as it is clear and distinct. If a writer can only rehash the cyclopedia or the text book, he would do well to decline to furnish papers; but every general practitioner of medicine and surgery, and as well every specialist in full practice, has so much information that he can communicate, that fortunately there is no need to weary the Section with page after page of matter already in print, that each may as well read for himself at his leisure. It is seldom necessary in our day to cite obsolete authors, except in purely historical studies, and it is questionable if long tables of bibliography should not be altogether omitted. These tables no longer prove the erudition of the writer, because they may be easily copied from the *Index Catalog* of the Surgeon General's Library and the *Index Medicus*.

The carefully written record of cases with appropriate comment is a style of medical writing that never grows old or obsolete. Hippocratic writings, almost the only ones of medicine that have lasted upwards of two thousand years, are full of case records and case histories, not the dry details, but an interesting summary.

The advantage to the consultant in having his papers read, is almost certain to cause him to write them short, so that his clientelage will read them. This advantage appeals to the consultant in a pecuniary sense, not less than the desire to go to posterity as an original worker and thinker. Every reader is not so fond of conciseness as LOUIS XIV., but many a consultant will be the better off by writing briefly and to the point.

An old and instructive story of LOUIS XIV., who loved conciseness, is to the effect that one day meeting a priest he said: "Whence came you—where are you going—what do you want?" The priest said:

"From Limoges, to Bruges; a benefice." "You shall have it," said the King.

The great writers and orators of the past, whose works have lived, have transmitted to us models of conciseness, and they have been so transmitted because of that conciseness. Those ambitions to live in future pages, after personality has long past, will eschew long articles, and write with compactness.

#### NOT A "NEW" RULING.

Our esteemed contemporary, the *Tri-State Medical Journal*, has been led into an error of statement through the inadvertent "sidehead" of an item in the JOURNAL of October 20, ult. The decision of the Illinois State Board of Health, declining to recognize a degree granted by a dental, pharmacal or veterinary school as the equivalent of any part of the minimum requirements fixed by the Board as characterizing a medical college as in good standing, is not "a new ruling;" on the contrary, it has been in force during the last two years, having been adopted at the January, 1892, meeting of the Board after a consideration of the evidence presented by the Secretary, DR. REILLY, as to the wide disparity which then existed in the qualifications for the degrees of the various schools.

Judging from the following comments of the editor of the *Tri-State*, the objection to the recognition of such degrees is as weighty now as then. DR. MOORE says: "There is a grand opportunity for fraud in this connection. All over the land are 'colleges' and 'universities' teaching dentistry, veterinary science and pharmacy as side-shows. They are insignificant schools for whose existence no good reason has ever been offered. To accept the degree from such a school of mongrel pedigree as equivalent to one year's study in a medical college of high grade is wrong, and can result only in a lowering of the medical profession."

But this is by no means to say that there are not many reputable and estimable dental, pharmacal and veterinary schools in existence, the scope and thoroughness of whose instruction might well entitle their graduates to be entered as second-year students in medical colleges of high grade. The difficulty lies in the want of uniformity in the requirements for these degrees, and in the absence of a recognized standard the State Boards probably do wisely in rejecting all. Such sweeping rejection should lead to organizations of the better classes of these schools similar to the American Medical College Association, membership of which is now generally recognized as entitling a college to recognition by State Boards.

#### "A CLERICAL ERROR."

An observant correspondent of the JOURNAL—DR. W. H. SHARP, of Parkersburg, West Va.,—calls attention to what he kindly styles "a clerical error"

in the editorial comment on "Smallpox in 1894," published in the issue of January 5. It was therein attempted to contrast the mortality from smallpox in the ante-JENNERIAN period—96 smallpox deaths out of every 1,000 deaths from all causes—with the actual number of deaths from smallpox in 1894—less than 3,000 out of a total of 1,170,000 deaths from all causes, or about 2.5 smallpox deaths out of every 1,000 deaths from all causes. As printed in the JOURNAL the number of deaths from smallpox out of the total deaths was given as 12,300, instead of the correct figures 112,300, thus weakening the arithmetical force of the argument for vaccination by about nine-tenths, as DR. SHARP points out.

## CORRESPONDENCE.

### "The Practical Importance of Well Established Facts In Therapeutics."

CHICAGO, Jan. 15, 1895.

To the Editor:—Under this head, your correspondent, Dr. J. H. Stallard, gives in our JOURNAL for Jan. 5, 1895, an interesting account of his own experience in using alcohol in the form of brandy or whisky, apparently to prove that it is a true tonic and restorative. His first point of proof is that after having climbed to a height of 10,000 feet one morning, he took a hearty breakfast and, after only an hour's rest, began his return when the "heat was intense" and over glacier ice "as irregular and uncertain as on board of a ship." What is not singular, the intense heat, the presence of undigested food in his stomach, with the excitement of his unusual walk brought on extreme irritability of the pneumogastric and whole vasomotor system of nerves, indicated by excessive vomiting renewed at every attempt to proceed. In this dilemma, after his digestive organs had been emptied of their contents and the "intense heat" of midday had somewhat subsided, he was given a full dose of brandy which, by its true anesthetic effect, so far lessened the excitability of his cerebral and pneumogastric nerve cells that he was enabled to resume and complete his journey under the impression that he had on "a pair of brandy boots." I suppose an equivalent dose of ether, chloroform or any other reliable anesthetic would have produced the same effect. But is there no difference between an anesthetic and a stimulant or cardiac tonic?

Your correspondent's second point of proof is, the fact that at about the age of 62 years he had a sharp attack of pneumonia, took half ounce doses of brandy or whisky every two hours for nine days and his "recovery was perfect." But if his recovery proves that the alcohol was a "stimulant and heart tonic," what will he say in regard to the case of an eminent physician and medical teacher in one of our Eastern cities, who had a severe attack of pneumonia after he was 60 years of age, was promptly bled freely from a vein in his arm, and treated strictly according to the antiphlogistic system of the first half of the present century, and not only made a perfect recovery, but lived in fair health to the ripe age of 83 years. Does it prove that venesection and antimony are stimulants and heart tonics?

The third point of proof implied by the personal history of your correspondent is that he has attained the age of 74 years still in good health, though he has drunk wine every day for over fifty years and as little water as possible. But, on the other hand, I well knew an eminent surgeon and teacher, who was through life a total abstainer from both

alcohol and tobacco, and was somewhat of a vegetarian besides, who continued his professional duties until he was 80 years of age and died of old age at 86 years. And I could refer to a score of similar cases, some of whom reached their 100 years. If Dr. Stallard's condition at 74, affords any proof that wine is a stimulant or heart tonic, the other cases must prove that simple water is equally efficacious, to say the least. But, in truth, such personal histories prove nothing of value, for every well read physician knows that we meet with individual cases of unusual longevity in all classes of society, sometimes in the midst of poverty and unsanitary surroundings with bad food and drink, and sometimes in the mansions of luxury. Such histories of individual cases of disease only show that some persons possess a tenacity of life that enables them to recover in spite of the most injudicious treatment when sick, and attain longevity in spite of both bad habits and bad surroundings. To determine the actual effects of alcohol or of any other agent, on the living body requires a widely different line of investigation, at least, something more than the impressions of the patient while under the influence of the anesthetic.

Yours truly,

N. S. DAVIS, M.D.

### Treatment of Typhoid Fever.

ST. FRANCIS, ARK., Jan. 8, 1895.

To the Editor:—Having become interested last summer in Dr. Woodbridge's articles on the abortive treatment of typhoid fever, I determined to test it at the first opportunity. I had seen and assisted in treating quite a number of cases of typhoid fever in the Memphis City Hospital, having been an interne there for nearly two years, and have no recollection of any cases being free from fever under three weeks, although treated according to the latest and most approved methods. Last fall I treated several cases according to Dr. Woodbridge's plan and was exceedingly pleased with the results. I did not succeed in cutting the disease so short as Dr. Woodbridge did, on account of the method being new to me, and for other reasons, only giving prescription No. 1 every hour for twenty-four hours, then the guaiacol and eucalyptol every three hours for twenty-four hours, thus alternating them as I thought necessary. I was surprised to see how uniformly the temperature would drop from the effect of these antiseptics so frequently administered, only to rise again on leaving them off or reducing dose or frequency of administration. All of these cases recovered and only one had any bad nervous symptoms. Two of them were free of fever on the tenth day of treatment, two on the thirteenth, one on the fifteenth, one on the sixteenth and one on the seventeenth. In the case running for sixteen days, all medicine was left off—on the tenth day—by mistake, for eight hours, and the temperature which had fallen to 99.5 rose again and was 104 for two evenings. The highest temperature in the two worst cases was 105.5, and in none was it less than 104 for a few evenings, thus showing them to be severe cases. One case on the eighth day of the disease had incontinence of feces, the only one having any bad nervous symptoms. I was forcibly reminded and impressed with what Dr. J. B. Herrick, of Chicago, said about the effect of antiseptic treatment of typhoid fever. In an article headed, "A Synopsis of nearly a Thousand Cases of Typhoid Fever," he says that there is no doubt but that the antiseptic treatment of typhoid fever prevents the development of nervous symptoms. This article was published in our JOURNAL some time ago. I regard the treatment as being a vast improvement over any other and a boon to humanity. Dr. Woodbridge simply carried to the full extent what has been advocated for some years by quite a number of the most prominent men in the profession, and I think it a practical success and

not a therapeutic theory. There seems to be no doubt but that this frequent administration of antiseptics has an inhibitory influence on the typhoid bacilli, checking their activity, hence preventing the development of toxins, the absorption of which no doubt causes the grave nervousness in so many cases. I will say, in conclusion, that in none of these cases did fever exist over twenty-one days after beginning.

Yours faithfully,

WM. BAYARD SHIELDS, M.D.

### Treatment of Typhoid Fever.

ORAN, Mo., Jan. 8, 1895.

To the Editor:—In our JOURNAL of January 5, I find a report on typhoid fever by Dr. Woodbridge and it reminds me of a report I made to the Southeastern Missouri Medical Association a few days before the Doctor made his report at Hot Springs. I reported a case of typhoid fever treated with *hyposulphite soda* and *Fowler's solution*, which gained over a pound a day during treatment. He ate his meals regularly, went to the table and to the privy (fifty yards distant from his hotel) his temperature ranging from 102½ to 105 for fifteen days. He ate largely of green apples, dates, oranges, lemons, anything he wanted (and could get), never complained of any pain, said he felt frstrate all the time, slept well, read the newspapers by day, and was a great Breckinridge man, they both being Kentuckians. I am as positive that this man had a genuine case of typhoid fever as I am that I am writing this squib.

Now what does my report and that of Dr. Woodbridge teach? Nothing, only that typhoid fever does not kill everybody that has it. I treated a babe, 2 years old, last week with as typical a case of typhoid fever as those described by Dr. Love in this same number of the JOURNAL. I gave it calomel and Dovers' powder 1 gr. each, every four hours for six days and *Fowler's solution* (Squibb's) ¼ of a drop every two hours during the same time. This case was clear of fever on the tenth day and called for food. Can Dr. Woodbridge or any other man, do any better for typhoid fever than I did in these two cases? We did not use the same treatment but obtained the same results. Therefore the treatment is not entitled to all the credit.<sup>1</sup> I gave my doses two hours apart, allowing some time for sleep between doses. Any doctor who gives medicine every fifteen minutes for twenty-four hours ought to have mild cases to treat or be dosed himself for the next twenty-four hours.

Dr. Woodbridge is an enthusiast, and evidently a good man, but there is nothing in his treatment that is new or an improvement on mine. Mine will only cure cases that would probably have gotten well without it—typhoid fever comes as near having its own way as any disease we have to treat. Dr. Woodbridge's treatment is like the homeopaths or the old woman's butter, "If it does no good it will do no harm." Dr. Woodbridge is full of enthusiasm; I am full of gall. This makes a stand off. He tells what he thinks is true; I tell what I think is true. Another stand off. The reader can take his choice of treatments—not forgetting that typhoid fever kills under all kinds of treatment, and that many cases get well under the most unfavorable conditions.

W. P. HOWLE, M.D.

### A New Truss—The Nagler Shield.

SAN FRANCISCO, CAL., Dec. 29, 1894.

To the Editor:—For the past few months I have been carefully investigating the virtues of a new mechanical device to act as a truss and abdominal supporter wherever such is indicated. It absolutely controls all protrusion and reduces

<sup>1</sup>This is a non-sequitur, for Fowler's Solution is an excellent germicide, so also is calomel, and sodium hyposulphite.—ED.

to a minimum all discomfort from pressure or friction. It consists in its main features of an aluminium shield, carefully molded to the abdominal periphery, and suitably modified to conform to the anatomic requirements of either sex. The shield is lined with soft felt, in which pockets are formed, which can be filled with additional packing, should any particular case demand such support.

In extreme cases a padded metallic ring, surrounding the penis is fastened underneath on top of arched cut away portion of the shield, and this ring is pressed against that part of the pad where the opening for the scrotum is set in and when so adjusted to the body completely controls all possible prolapsus.

The Nagler Shield.

The pressure for the truss is created by the fastening of an elastic belt around the body, which is attached to a series of pins placed around the borders of the shield; this can be graded to suit the amount of pressure required. An additional mechanism prevents all vertical movement.

The complete truss is so simple and yet so effectual that nothing but actual experience of its use will convince those unacquainted with its virtues. The lightness of the material—an infantile umbilical truss not weighing over one ounce—and the freedom from friction go far to commend the application of this truss in all reducible hernias or lax abdominal walls.

FRED W. D'EVELYN, M.D.

### One Hundred Thousand More.

PARKERSBURG, W. VA., Jan. 9, 1895.

To the Editor:—In your article on "Smallpox in 1894," in JOURNAL of January 5, occurs a clerical error on page 27, which destroys the force of the argument. Should read 112,300 deaths instead of 12,300, making the value of vaccination much less than it is.

Yours,

W. H. SHARP, M.D.

### Doctor Dana O. Weeks.

MARION, OHIO, Jan. 12, 1895.

To the Editor:—A mistake occurs in this week's issue of the JOURNAL, page 62, under Society News. Dana O. Weeks was elected President of Marion County Medical Society—not Dana O. Webb. Very truly yours,

O. W. WEEKS, M.D.

## PUBLIC HEALTH.

**Board of Health of North Carolina.**—The December *Bulletin* of the North Carolina Board of Health makes announcement of the resignation of the President, Dr. H. T. Bahnson, of Salem, to become a director of the State Hospital at Morganton. Dr. George G. Thomas, of Wilmington, has been elected to succeed to the presidency. Dr. William P. Beall, of Greensborough, has been appointed by the Governor to fill the place in the Board.

**Windmills for Sanitation.**—A paper, at the Mexican capital, reports that a new project is on foot for the better sanitation of the sewer system of the City of Mexico. It is proposed to construct twenty-five windmills, at a cost of \$25,-

000; these mills are to propel wheels or paddles within the sewers, and by them the rapidity of the current of the sewage is to be quickened.

**Disinfection of Fecal Matter.**—In a paper recently read before the Paris Academy of Sciences, M. Vincent claims that the best disinfecting agent for fecal matter and the contents of privies is sulphate of copper, especially if it has been previously acidulated with 10 per 1000 of sulphuric acid. For normal stools at a mean temperature of 16 C., disinfection is accomplished in twenty-four hours when the proportion of copper sulphate used is equal to 6 kilos per cubic meter; for typhoid stools 5 kilos, and for cholera stools 3.5 kilos per cubic meter are sufficient to destroy the microbes after a contact of twelve hours. This difference in the amount required is due to the fact that these pathologic stools are very fluid and contain pathogenic microorganisms which are less resistant than the saprophytes.

**Bacteria in School Rooms.**—In a recent communication to the Hamburg Medical Society, M. Ruete details the results of his bacteriologic examination of the air of school rooms. He made use of Hueppe's method and made his investigations at 2:30 in the afternoons. While these were always made under the same conditions the results were very variable. He found a minimum of 1,500 bacteria to the cubic meter, a maximum of 3,000,000, and a mean of 268,000. Analogous researches gave Hesse an average of only 9,500. Among the bacteria observed the author calls attention (*Bulletin Medical de Paris*) to a motile bacillus which does not develop on agar, but on gelatin plaques gives rise to circular colonies with crenated edges; it can also be cultivated on milk and potato; pure cultures kill mice in twenty-four hours and their blood is rapidly fatal to guinea pigs. Ruete has been able to extract toxins from the blood of animals thus killed.

**Prophylaxis of Tuberculosis.**—In his *Maladies du Soldat*, Professor Marvaud details the prophylactic measures employed in the French army against the spread of tuberculosis. These consist of: 1, the immediate discharge from service of all men affected with tuberculosis or likely to become so, such as those having weakly constitutions, vicious conformation of the chest, insufficient respiratory capacity, or hereditary tendency; 2, the prompt discharge of all who become affected during service; 3, preventive hygienic measures; location of barracks away from towns and on elevated and well-ventilated sites; thorough ventilation of squad-rooms, and day-rooms for the use of soldiers in inclement weather, antiseptics in spittoons and paraffined floors to prevent soiling with sputa, the disuse for a certain period of any squad-room in which cases have been developed, isolation wards, disinfection, attention to diet, the avoidance of sudden transitions from heat to cold, and the use of such exercises in the open air as tend to expand the chest. As the death rate from phthisis is 150 per cent. greater in the army than in the civil population of corresponding sex and age these prophylactic measures are of prime importance.

**Michigan State Board of Health.**—The Michigan State Board of Health held its quarterly meeting at the office of the Secretary, in the Capitol, at Lansing, Jan. 11, 1895. The meeting was called to order by President Frank Wells, of Lansing. Prof. Delos Fall, of Albion; Dr. Vaughan, of Ann Arbor; Dr. Gray, of Pontiac; Dr. Milner, of Grand Rapids; Dr. Granger, of Bay City, and Secretary Baker of Lansing, were present. The regular business including the auditing of bills and accounts was transacted. A special committee to report to the Board the advisability of entering upon the production of immunizing blood-serum for the use in the production of immunity from diphtheria, with a view of still

further testing, in this country, the efficacy of the method. Dr. Vaughan, Director of the Michigan State Laboratory of Hygiene, reported that he had thoroughly considered the subject and concluded that at the present time the expense would be too great for the State Board of Health to undertake. It was suggested that the Board should take action to protect the people against the use of spurious antitoxins. On motion of Dr. Granger the Board voted to appoint Prof. Victor C. Vaughan, M.D., Director of the Michigan State Laboratory of Hygiene, a special committee to test the immunizing properties of samples of antitoxin offered for sale in Michigan.

Dr. Baker offered the following preambles and resolutions which were unanimously adopted:

WHEREAS, An accurate and prompt registration of the deaths and the causes of deaths in each locality of this State would be of very great practical usefulness to the work of this Board, and consequently of great value to the people of Michigan; and

WHEREAS, Under the present law, which has not been amended since 1869, the registration of vital statistics has failed to give accurate results, and to present them sufficiently early to be of the greatest practical sanitary use and public interest; therefore

Resolved, That the Michigan State Board of Health earnestly recommends the enactment of an improved law for the registration and return of deaths (and also of births) which law shall provide for their immediate record, and prompt report to the State Department.

Resolved, That a committee be appointed by this Board to present the subject to the Legislature, and to urge such action; said committee to act independently or in conjunction with similar committees of the Michigan State Medical Society, Michigan Academy of Science, or other organizations, as may be deemed advisable.

The subject was referred to the Committee on "Statistics of Mortality and Sickness," with request to act in accordance with the resolutions.

Dr. Vaughan, the committee, to whom was referred the subject of suspected poisoning by dried beef, at Somerset Center, Hillsdale County, reported that he had examined the dried beef, and found it contained a capsulated bacillus which when injected into white rats and guinea pigs promptly killed them, showing that it was a poisonous germ. Dr. Vaughan also reported relative to suspected poisoning by pressed chicken at Sturgis. During a banquet some two hundred persons were poisoned. A sample of the chicken was examined at the State Laboratory of Hygiene, and found to contain a short capsulated bacillus which was poisonous, but not of such a virulent character as the one found in the dried beef. It was found, by inoculation, that the germ would kill guinea pigs, but did not kill rats.

Dr. Milner, of Grand Rapids, Committee on Schools, was directed to prepare a bill, for introduction in the Legislature, which shall regulate the employment of teachers in our public schools, and professional nurses who are affected with any communicable form of tuberculosis. Instances have been noted and referred to by Dr. Milner at a previous meeting, where it is probable that tuberculosis (consumption) has been contracted from a teacher.

On motion, the Board voted to direct the Committee on Legislation, Dr. Granger, of Bay City, to confer with members of the State Live Stock Commission and the State Veterinarian, to prepare bills for the improvement of the sanitary laws of the State, relative to live stock, and to look to the introduction and passage of such bills.

The proposed bill for a "State Hospital for Consumptives," in connection with the State Laboratory of Hygiene at the University, was read section by section, amended and approved by the Board. The objects of the hospital are: 1, the proper care and treatment of persons having the disease known as consumption, phthisis, or tuberculosis, in order that the spread of this disease may be lessened; 2, the

training and education of persons who shall go out from that hospital, in the best methods for restricting the spread of this dangerous disease; 3, the training, in such methods of medical students who are to practice medicine in Michigan so that they may know how to restrict tuberculous diseases; and 4, that physicians and others may be enabled to study this disease under favorable conditions, thereby obtaining knowledge useful for the prevention of the spread of this disease, and for its ultimate restriction or extinction in Michigan.

Dr. Baker presented the subject of the need for legislation to prevent the introduction of dangerous diseases into localities in Michigan. He stated that there is no specific law on this subject, although he has several times drawn bills and had them introduced in the Legislature for this purpose. The present law is not operative until after the local board of health has made and published regulations.

By invitation of the Governor, the Board met the Governor in his room, for conference relative to the work of the Board, and a proposed increase in its scope, one question being whether the public interests might be better subserved if the Board were given power to stamp out dangerous diseases in localities where for any reason the local officers were unable or unwilling to take the proper measures.

**State Sanitary Convention of Pennsylvania.**—Preliminary announcement. The Eighth State Sanitary Convention of Pennsylvania, to be held under the combined auspices of the State Board of Health and Vital Statistics and of the State Associated Health Authorities, will convene in the Supreme Court room, Harrisburg, Jan. 30, 1895, at 10:30 A.M. The reports of the several standing committees of the State Associated Health Authorities—namely, the Committee on Legislation (E. S. Wagoner, of Mechanicsburg, Chairman); the Executive Committee (Dr. Benjamin Lee, of Philadelphia Chairman); and the Committee on Publication (M. G. Lipfert, C.E., of Phoenixville, Chairman) will be read. The following subjects will be presented for discussion:

The Sanitary Treatment of Communicable Diseases; Compulsory Vaccination; The Best Means of Educating the General Public in Matters of Practical Hygiene; Typhoid Fever, the Curse of the Rural Districts; The Proper Use of Disinfectants.

An evening session will be held in the hall of the House of Representatives, at which subjects more especially connected with sanitary legislation will be presented. The Governor of the State, Gen. D. H. Hastings will be the presiding officer. The most prominent sanitarians in the State will take part in the discussions. While the attendance of local health authorities is expected to be very large, all persons of both sexes interested in the promotion of sanitary reform and organization will be welcome, and are urgently requested to attend.

Application for special rates for transportation should be made to the Secretary, 1400 Pine Street, Philadelphia. State railroad wished, and enclose stamp for return postage.

BENJAMIN LEE, M.D., Chairman Executive Committee.  
WM. B. ATKINSON, M.D., Secretary.

## ASSOCIATION NEWS.

**The Baltimore Meeting.**—The Committee of Arrangements has secured the new Music Hall for the meetings of the Association. This hall is just completed, and is one of the most comfortably arranged buildings in the country. The general sessions as well as all the section and committee meetings will be held in the same building. The rooms are large, comfortable, well lighted and ventilated. Access to the hall is convenient by lines of cable and trolley cars from all the hotels and in fact from any part of the city. The Committee on Halls has assigned rooms to all the sections. Chairmen or

secretaries of sections are requested to forward to the Secretary of the Committee of Arrangements titles of papers at an early date so that a preliminary program can be printed in the JOURNAL not later than March 1.

GEORGE H. ROHÉ, Secretary.

**Photographs of Members.**—Members of the Association who send their photographs to the JOURNAL will find their contribution to the collection acknowledged under the heading of Letters Received.

## SOCIETY NEWS.

**The Wapello County (Iowa) Medical Society** met January 3

**The Central District Medical Society** of Missouri held its regular meeting at Sedalia, Mo., January 3.

**Berks County (Pa.) Medical Society.**—The Berks County, Pa., Medical Society held its annual banquet at Mineral Springs, Pa., January 8.

**Erie County (N.Y.) Medical Society.**—At the annual meeting of the Erie County, N. Y., Medical Society the following officers were elected: President, Fred. W. Bartlett; Vice-President, Justin G. Thompson; Secretary, F. C. Gram.

**The Lucas County (Ohio) Medical Society** held its annual meeting in Toledo January 2. The following officers were elected for the ensuing year: President, John A. Wright; Vice-President, J. D. Howe; Secretary, F. O. Hunt.

**Schuylkill County (Pa.) Medical Society.**—The Schuylkill County (Pa.) Medical Society held its annual meeting in Pottsville January 8. The following officers were elected: President, C. W. Bankes, Middleport; Vice-President, A. P. Carr, St. Clair; Secretary and Treasurer, George Little, Tamaqua.

**Kalamazoo (Mich.) Medical Society.**—The Kalamazoo, Mich. Medical Society held its annual meeting January 8. The following officers were elected: President, O. A. Lacroes; First Vice-President, C. Van Zwaluwenburg; Second Vice-President, O. F. Burroughs; Secretary, J. W. Bosman.

**Milwaukee (Wis.) Medical Society.**—The Milwaukee, Wis., Medical Society held its annual meeting in that city January 8. The following officers were elected for the ensuing year: President, W. H. Washburn; First Vice-President, G. J. Kaumheimer; Second Vice-President, Lorenzo Boorse; Secretary, H. B. Hitz.

**Kansas City Academy of Medicine.**—The Kansas City Academy of Medicine held a regular meeting January 5. The following officers were elected for the ensuing year: President, John Puntton; Vice-President, V. W. Gayle; Secretary, J. W. Kyger; Treasurer, C. L. Hall. The annual banquet was held January 8, and the event was a brilliant one.

**Iowa State Medical Society.**—The forty-fourth annual meeting of the Iowa State Medical Society will be held April 17, 18 and 19, in Creston, Iowa, and the forty-sixth annual meeting of the AMERICAN MEDICAL ASSOCIATION will be held May 7, in Baltimore, Md., and it is hoped all will avail themselves of the benefits of these meetings and be present at both of them. The following are the chairmen of the different sections for the next meeting of the State Society: Medicine, F. M. Hiatt, Red Oak; Surgery, J. M. Emmert, Atlantic; Obstetrics and Gynecology, H. L. Getz, Marshalltown; Ophthalmology and Otology, H. B. Young, Burlington; Materia Medica, J. R. Guthrie, Dubuque; State Medicine and Hygiene, J. S. Braunsworth, Muscatine; Mental and Nervous System, F. S. Thomas, Council Bluffs.

The announcement program will be mailed about April 1.  
J. W. COKENOWER, M.D., Secretary.

## NECROLOGY.

JOHN MILLS BROWNE, ex-Surgeon-General, U. S. Navy. Born in Hinsdale, N.H., May 10, 1831. Graduated at the Medical Department of Harvard University in March, 1852. Appointed from New Hampshire, March 25, 1853; entered the service as Assistant Surgeon, and performed first duty on board the store-ship, *Warren*, Lieutenant commanding, Fabius Stanly, at Saucelito, opposite San Francisco; in September, 1854, the *Warren*, Lieutenant commanding, D. McDougall, proceeded to Mare Island, and became the temporary residence of Commander D. G. Farragut, the inaugurator and first Commandant of the Navy Yard; Medical Officer of the Navy Yard until May 10, 1855; then duty on board the coast survey steamer, *Active*, Lieutenant commanding, James Alden; attached to *Active* until November, 1857; *Active* employed in surveying the coast and harbors of California, Oregon and Washington Territories, in the winter of 1855-56, with the steamer *Massachusetts* and the sloop *Decatur*; *Active* engaged in the Indian war at Puget Sound;

JOHN MILLS BROWNE, M.D.

and in the summer of 1857, in connection with H. B. M. sloop *Sattelite*, occupied in settling the northwest boundary. Passed Assistant Surgeon, May 12, 1858; brig *Dolphin*, Lieutenant commanding, John N. Maffit, June 1, 1858, Home Squadron off Cape Verde, Cuba, *Dolphin* captured the brig *Echo* with over three hundred slaves destined for the Cuban market; *Echo* sent to Charleston, S. C., subsequently the surviving negroes were taken to Liberia in the frigate *Nisagra*; Oct. 1, 1858, steamer *Atlanta*, Commander D. B. Ridgely, Paraguay expedition; Dec. 25, 1858, Hospital Norfolk, Surgeon Ninian Pinkney; May 9, 1859, sloop *Constellation* Flag Officer Wm. Inman, Fleet Surgeon, Thos. D. Smith, flag ship of African Squadron; visited Madeira, Cape de Verde Islands, St. Helena, Liberia, St. Paulo de Loanda and other ports and islands along the west coast of Africa; Sept. 25, 1860, at night off Congo River, *Constellation* captured the bark *Cora*, with 705 slaves, who were sent to Liberia; commissioned as Surgeon, June 19, 1861; Dec. 23, 1861, steam sloop *Kearsarge*, Commander Charles W. Pickering, special duty coast of Europe; visited Cadiz, Algeciras, Gibraltar, Tangier, Ferrel, Brest, Cherbourg, Boulogne-sur-mer, Calais, Ostend, Flushing, London, Margate, Ramsgate, Deal, Dover, Folkestone, Hastings, Queenstown, Azores, Madeira, Teneriffe; off Cherbourg, June 19, 1864, *Kearsarge*, Commander John A.

Winslow, after an engagement of one hour and two minutes destroyed the rebel steamer *Alabama*; *Kearsarge* left Europe in August, 1864, for the Azores, and from thence proceeded to Fernando de Noronha, and Las Rocas, off Brazil, in search of the rebel steamer *Florida*; returned to Barbadoes, thence to St. Thomas, and arrived at Boston Nov. 9, 1864; Dec. 23, 1864, temporary duty Navy Yard, New York; April 29, 1865, Navy Yard, Mare Island; special duty to superintend the erection of the Naval Hospital at Mare Island; duty in charge of the hospital at Mare Island 1870-71; Fleet Surgeon Pacific fleet 1871-72. Commissioned as Medical Inspector Dec. 1, 1871; Navy Yard and Naval Hospital, Mare Island, 1873-74; Fleet Surgeon, North Pacific station, 1874-76; Naval Hospital, Mare Island, 1876-80. Commissioned as Medical Director, Oct. 6, 1878, President of Medical Examining Board, Washington, D. C., 1880-82; member of Board of Visitors, Naval Academy, Annapolis, Md., 1881; naval representative at the International Medical Congress, London, England, 1881; duty in charge of Museum of Hygiene, 1882-85; duty on Board of Naval Regulations, 1882; member of National Board of Health 1883; naval representative at the International Medical Congress, Copenhagen, 1884; Member of Retiring Board, 1885-88. Chief of Bureau of Medicine and Surgery, with title of Surgeon-General of the Navy, from April 2, 1888, until date of retirement, May 10, 1893. (Official record in Naval Register.) Died Dec. 7, 1894.

WILLIAM DETNOLD, M.D., one of the senior surgeons of New York City, and a founder and first President of the New York County Medical Association in 1884, died Dec. 26, 1894. He was born in Hanover, Dec. 27, 1808. After taking his medical degree at Göttingen in 1830, he was for a time in the surgical service of the Army. He took up his permanent residence in New York in 1837, and very soon thereafter became identified with the College of Physicians and Surgeons; of this school he was Emeritus Professor of Clinical and Military Surgery at the time of his decease. This embraces a period of more than half a century. He was one of the founders of orthopedics in this country; his first clinic dating as early as 1841. At the opening of the Civil War (1862), he was made full Professor of Military Surgery and Hygiene. His services at this time were much in request in the organization of medical corps and hospitals, especially those that were called into being in the vicinity of New York City, for the use of the State volunteers. He was an infrequent writer on medical topics, but his little book on club foot and some analogous subjects is one of the mile-stones of the pre-Listerian epochs of orthopedy. He was an ex-Vice-President of the Academy of Medicine and an ex-President of the Medical Relief Fund for Widows and Orphans. He had been a Consulting Surgeon to the Presbyterian Hospital. General paralysis was assigned as the cause of his last illness and death.

HENRY GOLDTHWAITE, M.D., of New York City, died January 4, aged 53 years. He was a native of Mobile, the son of the late Judge of the Supreme Court of Alabama. He was graduated from Princeton College in the class of 1860. He became a Confederate staff officer, attaining the rank of Major. After the war, he was in business in his native city, but he adopted medicine as his preferable pursuit. He graduated from Bellevue Hospital Medical College in 1876, and was next an interne at the Hospital and an instructor in the College. In 1878 he became one of the physicians resident at the Fifth Avenue Hotel, and it was there that he died somewhat suddenly from cerebral hemorrhage, on the date above named. He was twice married. He was a member of several local societies, and one of the visiting staff of the City or Charity Hospital.

CHARLES WRIGHT, M.D., of Carroll, Ala., January 3.—Jonathan Bemis, M.D., of Cambridge, Mass., January 6, aged 84.—E. H. Porter, M.D., of Columbia, Mo., January 4.—William Mercer, of Princeton, Ill., January 4, aged 80.—F. A. White, of Philadelphia, Pa., January 8, aged 38.—Stephen W. Root, of New York, January 9, aged 51.—Joseph S. Fitzgerald, of New York, January 8.—G. C. Upson, of Cuyahoga Falls, Ohio, January 7, aged 73.—J. D. Egelston, of Olathe, Kan., January 11, aged 67.—A. C. Hallam, of Brooklyn, N. Y., January 9, aged 49.

## BOOK NOTICES.

**Travaux d'Electrotherapie Gynecologique, Etc., Etc.** By G. APOSTOLI. Paris. 1894.

The volume before us is a collection of articles written on the subject of electro-therapeutics in gynecology, and from the prospectus we learn that it will be published semi-annually. The editor has very industriously sought all foreign publications for writings on his specialty and has in most cases translated them bodily into French and the result is this volume of 720 pages. The Americans quoted are Drs. Rockwell, Goelet, McGinnis, Buckmaster, A. Laphorne Smith, F. H. Martin, Massey, Skene, Mundé and J. H. Kellogg. Those who wish to keep pace with the entire literature of this subject will find this volume a necessity.

**Sexual Neurasthenia (Nervous Exhaustion), Its Hygiene, Causes, Symptoms and Treatment, with a chapter on diet for the nervous.** By GEORGE M. BEARD, A.M., M.D., Edited with notes and additions by A. D. ROCKWELL, A.M., M.D. Fourth edition. New York: E. B. Treat. 1895. Price \$2.75.

This well-known book has, as will be seen, passed to a fourth edition. A chapter on Sexual Erethism has been inserted in this edition in order to keep pace with the growing literature on the subject. In the formulas, Mr. Rockwell has translated the old English weights and measures into the decimal system, instead of writing them in that system *de novo*. The result is that the decimals are too fractional to conform to any known prescription in the metric system. The old system is also given. The work is an excellent one, and well deserves the compliment of a fourth edition.

**Twenty-fifth Annual Report of the State Board of Health of Massachusetts.** Boston. 1894.

Bearing in mind the noble record made by this Board in the last quarter of a century, and the high class of its annual reports, we naturally turn to the new volume to see if it keeps up the standard established by its predecessors, and are pleased to see that the mantle of Bowditch has fallen on worthy shoulders in the person of Chairman Wolcott. The present volume includes the general report, and a series of special reports on the subject of Water Supply and Sewerage; Weekly Mortality Reports of Cities and Towns; Reports of Infectious Diseases; Reports of Food and Drug Inspection; Isolation Hospitals for Infectious Diseases, and Report on the Health of Towns.

Apart from the chemists' reports, in themselves extremely valuable as showing careful and painstaking work, we must notice the article of the Secretary, S. W. Abbott, M.D., on Isolation Hospitals. After a review of the origin of this special class of hospitals, the author mentions the isolation hospitals of the principal cities of Europe, and gives plans of some of them. This will be found invaluable for health officers desiring to construct similar hospitals.

**Saint Thomas' Hospital Reports.** New series. Edited by Dr. T. D. AGLAND and MR. BERNARD PITTS. Vol. xxii, pp. 614. London: J. and A. Churchill. 1894.

This volume contains the statistical reports of this famous hospital, for 1892 and 1893, and its publication was this year delayed that the calendar and prospectus for 1894 might be included. The papers in the volume are generally excellent, and well reflect the existing state of British medicine and surgery. They are as follows:

i, The Treatment of Hallux Valgus by H. H. Clutton; ii, Case of Separation of Lower Epiphysis of Femur—Gangrene, Amputation, Pyemia, Death, by H. H. Clutton; iii, Traumatic Separation of the Upper End of the Femur in Early Life, by William Henry Battle; iv, Acute Osteo-periostitis

of the Femora, etc., by William Henry Battle; v, Acute Bronchiectasis, by Seymour J. Sharkey; vi, Pregnancy in a Uni-cervical Bicornate Uterus, by W. W. H. Tate; vii, Sterilized Surgical Dressings and Sterilized Water, by Edmund White; viii, A Case of Gangrene of Foot with Sugar in the Urine, Amputation, by Cuthbert S. Wallace; ix, The Removal of the Uterine Appendages for Uterine Myoma, with an account of Twenty Cases, by Chas. J. Cullingworth. The remainder of the volume is taken up with the reports of the several departments of the hospital for the years 1892 and 1893. There is a very interesting biography of the late George Rainey who was connected with Saint Thomas Medical School for nearly sixty years, and for nearly forty years as a teacher of anatomy, and demonstrator of the microscope.

## MISCELLANY.

**Dr. Charles G. Carleton**, of Lawrence, Mass., has been appointed City Physician of that place, *vice* Dr. Howe resigned.

**Nomenclature of Diseases.**—It is stated on the authority of Mr. W. Fleming, that the new edition of the "Nomenclature of Diseases of the Royal College of Physicians of London," will not be ready for some months. The revision of 1880 was published in 1885, and that of 1890, according to the foregoing statement will probably be ready in 1895.

**Injection of Air in Tuberculous Peritonitis.**—Folet, of Lille, at the Académie reports a case of tuberculous peritonitis, in which after withdrawal of six liters of fluid, he injected three liters of air in the abdominal cavity. The fluid was not reproduced eight months afterward and the woman's health remained excellent.

**Another "Citizen's Complaint" Impending.**—The following is from *Puck*:

"Across the Court.—Mrs. Keegan: 'Fer hivin's sake, Mrs. Casey, phwut is thot turrible shmellin'smoke?' Mrs. Casey: 'It's Mrs. Dooney below wid phwut she calls disinfectants.' Mrs. Keegan: 'Well, will yez plaze tell her from me thot if she don't shtop it Oi'll complain to the Board of Hiltth?'"

**New Journals.**—The *Journal of Medicine and Science*, published in Portland, Maine, starts its second number with the announcement that its "circulation" is 30,000. We trust that the affidavit editor may always be able to retain so handsome a circulation.

The *Dental Digest* is on our table, an excellent journal handsomely printed and carefully prepared.

**The Vermiform Appendix in Hernia.**—Kraft, (*Nordiskt Medic. Arch.* No. 23, 1894) reports seven cases of hernia; in three cases the sac contained the appendix alone, and in the remaining four cases he found the appendix with a knuckle of intestine. In practice when the appendix was neither gangrenous, nor perforated he reduced it; but in case of gangrene or perforation, resection was indicated.—*Revue Internationale de Medecine et de Chirurgie pratiques.*

**Students in German Universities.**—Ascherson's *Universitäts Kalendar* gives the following figures for the twenty German universities in 1894: The total number of students is 28,448, 8,684 of whom study medicine; 7,776 law; 3,336 Protestant theology, and 1,469 Catholic theology. Berlin heads the list with 4,265 students; then comes Munich with 3,744; Leipsic with 2,764; Halle, 2,154; Tubingen, 1,477, and so on. Ros-toch is the lowest, with 476.

**Treatment of Synovial Ganglion.**—Professor Duplay in a recent article (*Arch. General de Méd.* December, 1894), recommends the return to the former practice of iodine injection. The skin is to be well washed and sterilized. The hypodermatic needle is then introduced into the skin and made to glide

over the swelling a little, so that the opening into the sac and through the skin may not be opposite. From five to ten drops of the tincture of iodine are then injected, the amount varying according to the size of the ganglion; an aseptic cotton pad is applied over the puncture, which sometimes requires to be repeated. M. Duplay has had no failure, but some cases required more than one operation.

**Mentholated Oil.**—One of the remedies employed by Dr. Louis Martin, chief assistant to Dr. Roux, is this oil. It is referred to in a recent number of the *Bulletin Medical*, in a lecture delivered at Pasteur Institute. Its use is to avert broncho-pneumonia in cases under treatment by the serum, and one cubic centimeter is given once a day. The oil is composed of 4 grammes of menthol to 100 grammes of the oil of sweet almonds. As to the local treatment of cases of diphtheria, the lecturer states that caustic treatments are to be excluded. Phenic acid and sublimate solutions are now little used. Dr. Roux counsels the washing three times a day with solutions of boric acid or a solution of Labarraque's liquor, fifty grammes in one liter of boiled water. The feeding of children, under the serum treatment, should not be changed. They should be well supported, whenever the existence of serious albuminuria does not compel the employment of an exclusive milk diet.

**Cocain in Rigidity of the Uterine Neck.**—Farrar (Obstetrical Society of London November, 1894) has successfully employed cocain in two cases of rigidity of the cervix in the course of labor. In the first case, a primipara, the labor had been retarded more than forty-eight hours. Chloroform had been administered without relief; intending to incise the neck, he applied a compress saturated with a 10 per cent. solution of cocain and retained it for three minutes. On examination he found that even in this short space of time, dilatation had progressed with rapidity, and the case terminated normally. The second case was a primipara 40 years of age, and there was a rigidity of the cervix which had resisted the pains for three days, and as well all the means of non-operative dilatation. The application of a 10 per cent. solution of cocain caused a rapid dilatation.

**Pigmentation from Arsenic.**—Richardiere recently presented a patient at the Hospitals Medical Society of Paris (*Ann. de Derm. et de Syph.*)—a female aged 19, suffering from adenia—in whom injections of 42 drops of Fowler's solution and the internal administration of 500 drops of the solution produced a general pigmentation resembling the skin of a mulattress and almost black in the axillæ, neck and fingers. After ceasing the use of the arsenic the pigmentation decreased and was followed by desquamation. This pigmentary deposit was the principal sign of arsenicism, which was manifested otherwise only by a slight diarrhea and some paresis of the right leg. M. Rendu asked whether the generalized character of the pigmentation did not point to tuberculosis of the supra-renal capsules.

**Uses of Erysipelas Serum.**—Emmerich has recently experimented with serum from erysipelatosus animals as to its effect upon anthrax. After infecting rabbits with the latter disease he injected up to 20 cc. of the serum either into the peritoneal cavities or under the skin; these injections were repeated twice daily for two or three days. No anthrax developed. The author thinks (*Gaz. Med. de Liege*), that we may possibly employ the serum with success in the treatment of tuberculosis. He inoculated rabbits by introducing the tubercle bacilli into the anterior chamber of the eye, and having found the tubercles there developing he then infected the animal with the erysipelas microbes, whereupon the tuberculous process was slowed but not stopped. Emmerich concludes that his experiments warrant further researches into the uses of erysipelas serum, not in human tuberculosis alone but also in other infectious diseases, such as glanders, syphilis, tetanus, etc.

**Pyoktannin in Blennorrhagia.**—According to Vratich, No. 11, 1895, Posselt has employed pyoktannin in eighty-five cases of blennorrhagia, thirteen of which were subacute, twelve chronic and sixty acute, also two cases of blennorrheal con-

junctivitis and two cases of blennorrheal cystitis. The intra-urethral injections were made from two to four times a day with solutions of from 1 to 1000, to 1 to 2000. The patient was directed to retain the injected liquid one minute. In sixty-eight patients the injections were painless, in three there were intense pains but inconstant, and in one the author was obliged to relinquish the treatment on account of the pain. After a lengthy account of the microscopic appearances of the pus and the gonococci, the author concludes, by stating that pyoktannin is a good remedy in the treatment of blennorrhagia, but it must be used with care, on account of its irritant action, and care taken that the solution is not too concentrated; 1 to 1000 to 1 to 2000 should be the maximum, but that which renders pyoktannin little appropriate in private practice is the violet stain which it gives the hands, and the under linen of the patient.

**Local Application of Carbolic Acid.**—Cerné, of Rouen, reports the two following cases in the *Normandie Medicale*: A diabetic male had an insignificant wound of the leg dressed with a compress wet with a weak carbolic acid solution; this produced gangrene which increased in size daily. The patient went to an empiric who replaced the carbolic acid by an ointment of some sort and the gangrene was arrested. The second case was that of an alcoholic, with sclerosis and perforating ulcer of the left great toe; this was dressed with a carbolic solution of 1 to 40; on the second morning all the end of the toe was gangrenous. These cases show the dangers which may result from the local application of carbolic acid, especially if made by the patient himself—that is to say, without precaution or measure. Caution should be exercised in the use of carbolic dressings; the danger is greater when, from any cause, the tissues have less than their normal vitality.

**A Deserved Tribute.**—Treating of the abridgment of *Observations upon the Medical Department of the British Army*, made by Brevet Lieutenant-Colonel Alfred A. Woodhull, U. S. A. Medical Corps, the reviewer of the *British Medical Journal* says, "the abridgment is such an admirable summary of the organization and regulations of our [the British] army medical department that it might be perused with advantage by the medical officers themselves; every point, almost, is reviewed with surprising accuracy and any misstatements are of the most trifling character. We have always been struck with the general excellence of reports issued by the War Department of the United States, both as regards matter and form. It would seem in America that when a competent officer is selected to report he is allowed a free hand as to scope, style and length; his work is apparently not mutilated by superior intelligence at headquarters, nor cut down by a stingy printing office." Surgeon Woodhull himself is spoken of in an equally laudatory manner; his competency to criticize is fully acknowledged and frequent citations warrant the reviewer in closing with the remark that, "From all of which it will be seen that our American cousin is a just as well as a frank critic in army medical matters."

**Alterations of the Urine in Malaria.**—At a recent séance of the Vienna Imperio-Royal Medical Society, reported in *La Semaine Medicale*, von Limbeck related the results of researches which he had made in two cases of malaria. In these cases the elimination of nitrogen was in relation with the elevation of temperature; the proportion of urea and the total quantity of nitrogen were not modified; the elimination of ammonia also was in direct relation to the elevation of temperature; the quantity of urea was augmented but the relation between the ammonia and the total quantity of nitrogen was normal. During the febrile accession the quantity of phosphates was found diminished; they did not increase until after the access. Freund had also found a retention of phosphates during the febrile stage in some other infectious diseases. The elimination of chlorids, contrary to what occurs in other infectious diseases, is enormously increased during the malarial paroxysms; this fact is so characteristic that the author thinks it may be accorded a real diagnostic value.

**Columbia College.**—At a meeting of the trustees of Columbia College, at New York, January 7, it was announced that two large gifts had been made to the College of Physicians and Surgeons. One is of \$350,000 from Cornelius, William K., Frederick W., and George W. Vanderbilt, who contributed an equal amount each. The other is from William D. Sloan, who will erect a new maternity hospital to connect with the present one, the whole to be known as the Sloan Maternity Hospital. The estimated cost is \$200,000.

### Hospital Notes.

**FREE HOSPITAL FOR WOMEN.**—The new Free Hospital for Women at Boston, Mass., was formally opened January 1. There are twenty patients in the institution.

**St. JOSEPH'S HOSPITAL.**—An addition to St. Joseph's Hospital at Bloomington, Ill., is contemplated; the estimated cost is \$1,000.

**A NEW HOSPITAL FOR INSANE.**—Estimates have been prepared for the rebuilding of the hospital for the insane at Anna, Ill., which was recently destroyed by fire. The Legislature will be asked to appropriate \$200,000 for that purpose.

**Dr. R. D. BURNS**, of Allegheny, Pa., has been elected the resident physician at the Allegheny General Hospital, *vice*, Dr. Shaler resigned.

**THE LANE HOSPITAL** at San Francisco, Cal., was formally opened January 8. The building will accommodate 100 patients and cost \$230,000.

**GRADY HOSPITAL.**—The annual report of the Grady Hospital at Atlanta, Ga., shows that 1,640 patients have been treated at that institution during the past year.

**THE NEW MERCY HOSPITAL** at Des Moines, Iowa, will be ready for occupancy February 1. The total cost will be about \$20,000.

**NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.**—The tenth annual report of the New York Post-Graduate Medical School and Hospital shows that 17,833 patients have been treated in the dispensary and 1,300 in the wards.

**CHILDREN'S HOSPITAL, BUFFALO, N. Y.**—At a meeting of the managers of Children's Hospital at Buffalo, N. Y., January 3, it was decided to appropriate the \$1,200 raised at the Christmas sale for the endowment of four free beds.

**FOR A CONSUMPTIVE HOSPITAL.**—It is reported that the estate of Gen. Benjamin F. Butler has decided to turn over Old Fort Union in New Mexico for the use of consumptives. The property contains about 67,000 acres.

**St. TIMOTHY'S HOSPITAL PHILADELPHIA.**—Under the will of Henry Klein, M.D., of Philadelphia, liberal gifts have been left to three religious bodies having their headquarters in that city; the residue of his estate is to go to Saint Timothy's Hospital.

**MASSACHUSETTS HOSPITAL FOR INSANE.**—The State Asylum at Waverly, Mass., has received a much-needed remembrance under the will of the late Thomas E. Proctor, of Boston. The managers of the General Hospital are to be made the custodians of \$100,000, that will be in trust until it shall with accrued interest reach the value of \$400,000. Then the amount may be used in the construction of buildings, at the new grounds of the McLean Asylum for the Insane at the place named above, to be devoted to that branch of the General Hospital.

### Louisville Notes.

**Dr. C. J. WALTON.**—Dr. Clairborne J. Walton, of Hodgenville, Ky., is mentioned as a candidate before the Republican Convention for nomination as State Auditor. Dr. Walton was a Brigade Surgeon in the Union Army under Gen. S. W. Price, and during Harrison's administration was Pension Agent.

**Dr. JAMES WEIR, JR.**—Dr. James Weir, Jr., of Owensboro, has been tendered the chair of Nervous and Mental Diseases in the Gross Medical College of Denver, Colo., by the Dean of that College, Dr. F. H. Hawkins. The Doctor has not as yet accepted the call.

**PURE FOOD EXPOSITION.**—This Exposition has again been postponed, at the request of the grocers interested. Many manufacturers of food products who were unable to get their exhibits ready during the holiday season, have consented to make their displays if the exposition is postponed. The date now set is the first or second week in March, and it will continue three weeks.

**BLOOD POISONING.**—It is greatly to be regretted that so many surgeons fall a martyr to their calling, but it seems to be an almost daily occurrence for trouble of more or less serious character to fall to the lot of the surgeon. Dr. Ap. Morgan Cartledge, of this city, has been confined to his bed for some weeks the result of a wound received while operating upon a septic case of appendicitis. He is much improved at the present writing though still confined to his room. Dr. Arch Dixon, Jr., of Henderson, is also the victim of a similar accident, having been quite ill in Frankfort whether he had gone soon after, as the result of inoculation.

**Dr. W. L. CLAY.**—Dr. Clay, a member of the prominent Clay family of Paris, this State, was found lying dead in his bed at his home in this city—the coroner's verdict being apoplexy. Dr. Clay was born in Paris, Ky., fifty-five years ago. He had lived in this city for the past sixteen years. He belonged to General Morgan's command during the late war and was a member at the time of his death of the Confederate Veterans' Association of Lexington, Ky.

**STATE BOARD OF HEALTH.**—This Board held a meeting on the 5th inst., those present being Dr. Jos. M. Mathews, Louisville, President; Dr. J. N. McCormack, Bowling Green, Secretary; Drs. George Beeler, Clinton; Wm. Bailey, Louisville; Arch Dixon, Henderson. Dr. J. N. McCormack was unanimously elected Secretary, his term of office having expired. Several cases of alleged violation of the Kentucky practice law came before the Board, and a number were refused licenses. The case of Dr. H. H. Gwynn, of Louisville, was taken up, as he had asked for a rehearing. As the applicant was not present, his examination papers were read, and the answers appearing unsatisfactory in every branch his application was denied. Dr. Gwynn has been tried once for practicing illegally, and fined. He came before the Board and stood an examination, and upon these papers was refused a license.

During the session the following telegram was received from the Governor:

"Information received that cattle are dying at Nicholasville, Jessamine County, presumably from pleuro-pneumonia. Please take immediate steps to investigate." JOHN YOUNG BROWN.

Instructions were immediately wired Dr. E. T. Hagyard, State Veterinarian, at Lexington, to proceed to Nicholasville, investigate and report to the Board. The only cases of pleuro-pneumonia among cattle were those of the Harrison County epidemic, seven years ago, which was stamped out at a cost to the State of \$2,400. The State Veterinarian has rendered the report of his investigation of the alleged cases of pleuro-pneumonia in cattle. He found the cattle complained of in a remote part of the county and four of the herd had died, not from pleuro-pneumonia but from inflammation of the stomach caused by some poison. This is the second report recently which has been proven without foundation, in regard to pleuro-pneumonia in Kentucky cattle. The investigation was complete, and is thoroughly to be relied upon, and Dr. McCormack will officially report the above facts to Governor Brown.

**FALLS CITY MEDICAL SOCIETY.**—This society met at the Kenton Club, on the evening of the 9th inst., the guest of Dr. Louis Frank. The paper of the evening was read by Dr. Frank; the subject, "Empyema." Two cases were reported in which operations of resection of the ribs was made; in one of them a solution of iodoformized oil was injected into the cavity, under which treatment the case made a rapid recovery. Dr. Howard reported some cases relieved by hypnotic suggestion.

**DEATH REPORT.**—The report for the week gives a total of eighty-two deaths. The mortality from pneumonia still exceeds that from any other disease, there being seventeen from this cause and ten from consumption.

**CITY HOSPITAL.**—Superintendent Barbour states that the Hospital is so crowded that orders have been given to the attending physicians to discharge all patients that can possibly leave the hospital, in order to make room for the new applicants.

**MASONIC WIDOWS' AND ORPHANS' HOME.**—At the regular annual meeting of the directors of the Home, the following staff was elected for 1895: Dr. P. B. Scott, Physician in Charge; Dr. John G. Cecil, Consulting Physician; Dr. Frank Simpson, Visiting Physician; Dr. Henry E. Tuley, Assistant Visiting Physician; Dr. Ap. Morgan Vance, Visiting Surgeon; Dr. Wm. Cheatham, Oculist and Aurist; Dr. W. B. Pusey, Assistant Oculist and Aurist; Dr. I. N. Bloom, Dermatologist; Dr. Chas. E. Dunn, Dentist; Miss Anna Davies, Resident Nurse.

**THE HOSPITAL COLLEGE OF MEDICINE OF LOUISVILLE** entered upon its twenty-first annual session on the second day of the current month under the most favorable auspices. There were 172 matriculates at the beginning of the session, being the largest number on the opening day of any previous year in the history of the college. One year ago the college moved into the handsome new building provided for it by the Trustees of the Central University of Kentucky, of which it is the Medical Department. Since that time the laboratories have been thoroughly equipped and in both the clinical and laboratory teaching additional instructors have been provided. This college was the first of the Southern colleges to adopt the three-year graded course, and for several years the classes were depleted in consequence. The large attendance at the opening of this session demonstrates that the profession approves of the advanced position taken by this college, and that professional sentiment in the South is in thorough accord with that of the North and East, relative to higher medical education.

### Washington Notes.

**MEDICAL SOCIETY OF THE DISTRICT.**—The stated meeting of the Society was held on the 3d inst., and the following officers elected: Dr. S. C. Busey, President; Drs. Thomas N. McLaughlin and Geo. L. Magruder, Vice-Presidents; Dr. Thomas C. Smith, Corresponding Secretary; Dr. Samuel S. Adams, Recording Secretary; Dr. C. W. Franzoni, Treasurer; Dr. E. L. Morgan, Librarian. Drs. J. T. Winter, E. F. King, C. W. Richardson, Censors; Drs. C. H. A. Kleinschmidt, G. N. Acker, S. S. Adams, G. C. Ober, W. S. Bowen, Board of Examiners. The constitution was amended so as to allow prominent members (non-medical) of the different scientific departments of the National Government to become members of the Society by invitation. Two new committees were created, viz., Committee on Public Health, composed of seven members which shall report in January at the stated meeting of the Society, on the general health of the District. Committee on Legislation, composed of seven members which shall have charge of all matters of a legal character.

At the regular weekly meeting of the Society, held on the 9th inst., Dr. Kinyoun, of the Marine-Hospital Service, presented the subject of antitoxin treatment of diphtheria to the Society in his usual clear, concise and scientific manner, and in conclusion urged the importance of the supervision of the Government over all manufacture and distribution of the new substance, antitoxin. Dr. Walter Reed, Surgeon U. S. A., opened the discussion, and added considerable information to that already imparted by Dr. Kinyoun. He called special attention to some personal experiments at the Museum in this city, and showed how his bacteriologic test was delayed by the previous application of antiseptics to the mucous membranes from which cultures were afterward made. Dr. Lamb presented a case and specimen of appendicitis.

**THE WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.**—The two hundred and twentieth meeting of the Washington Obstetrical and Gynecological Society was held on

the 4th inst. Dr. G. N. Acker reported a case of ante-partum hemorrhage with death of child, and Dr. E. L. Tompkins presented a patient with polio-myelitis anterior, and read a very instructive paper on the subject. Both papers were very fully discussed. Dr. J. W. Bovee presented two uteri with appendages; one removed per vaginam, the other by abdominal section.

**WORK OF THE INSANE ASYLUM FOR THE MONTH OF DECEMBER.**—Dr. W. W. Godding, Superintendent of the Government Hospital for the Insane, has submitted to the Commissioners the report of his office covering the month of December. During that period there were twenty-three patients admitted for treatment, of whom fourteen were white and nine colored. Of the whites nine were men and five females, with six colored men and three colored females. Fourteen patients were reported as discharged or died during the month. Four white males and two females were discharged, and two colored males. Three white males died during the period and one white female, while for the colored people one death in either sex is reported.

**HEALTH OF THE DISTRICT.**—The report of the Health Officer for the week ended December 29 is as follows: Number of deaths (still-births not included): White, 63; colored, 55; total, 118. Death rate per 1,000 per annum: White, 16.33; colored, 30.10; total, 20.80. Death rate per 1,000 per annum for corresponding week last year, 21.70. Still-births: White, 3; colored, 2; total, 5.

The following is the report for the week ending January 5: Number of deaths (still-births not included): White, 65; colored, 50; total, 115. Death rate per 1,000 per annum: white, 11.40; colored, 27.36; total, 22.25. Death rate per 1,000 per annum for corresponding week last year: White, 7; colored, 12; total, 19.

**FIRE IN THE FREEDMAN'S HOSPITAL.**—A fire occurred in this hospital on New Year's day which caused considerable alarm, but little damage. Origin, defective flue. Protection from such occurrences has already been requested by the new surgeon in charge, Dr. D. H. Williams, late of Chicago, who has asked for fire plugs, fire escapes and brick buildings to take the place of the frame ones now in use. Dr. Williams is making this hospital a model institution.

**EXAMINATION OF POTOMAC ICE BY THE ARMY MEDICAL MUSEUM.**—The cutting of ice in the Eastern Branch, at the end of South Capitol Street, was the subject of a number of complaints recently received at the Health Office. Inasmuch as this is the place whence all the dead animals are shipped to Mann's desiccating establishment, Dr. Woodward determined to have a thorough investigation made of the quality of the ice. Accordingly, he sent a sample to the Army Medical Museum to have a bacteriologic test made. The report to Dr. Woodward from the Medical Museum is given below:

*Dear Sir:*—I beg to inform you that the specimen of ice forwarded by you on the 3d inst. has been subjected to a bacteriologic examination with the result that with five plates made, each with one cubic centimeter of water, only a few colonies of the bacillus convolutus, a common water organism, were found.

I may state that this specimen, to my surprise, contains fewer colonies of bacteria than any of the other specimens of ice so far examined by us in the laboratory.

WALTER REED,  
Major and Surgeon, U. S. A.

**THE PROVIDENCE HOSPITAL.**—The annual report of this excellent institution shows the large amount of good work done during the past year. During the year just passed a number of improvements have been made in the Hospital, thus keeping it thoroughly abreast with the best hospitals in the country. We desire to note, in particular, the introduction of steel ceilings in the wards, corridors and private rooms, by which the same are rendered more cleanly and at-

tractive, while at the same time, they are a great improvement from a sanitary point of view. The hospital has been newly painted throughout, and numerous improvements in the plumbing and ventilation have been made, all of the most modern pattern. During the past year the course of instruction for the sisters and nurses which was outlined at the last annual meeting has been put into practical operation.

**CHILDREN'S HOSPITAL.**—A supply of antitoxin has just been received from Berlin by the Children's Hospital, to be used in cases of diphtheria at the hospital. The annual charity ball for the benefit of the hospital has been arranged for and will soon take place.

**CENTRAL DISPENSARY AND EMERGENCY HOSPITAL.**—The directors are seriously considering the enlargement of the building to meet the increased demands of patients. This hospital is the center of clinical teaching in the District.

**SIBLEY MEMORIAL HOSPITAL.**—The admirably located and splendidly equipped Sibley Memorial Hospital, founded by Wm. J. Sibley, corner of North Capitol and Pierce Streets, will be formally opened for patients about February 1. Consulting physicians recently chosen are Drs. W. W. Johnston, J. Ford Thompson, Z. T. Sowers, S. S. Adams; medical staff, Drs. H. B. Deal, D. Olin Leech, Frank Leech, G. C. Ober, D. B. Street, J. L. Suddarth, J. T. Winter, W. C. Woodward; surgical staff, Drs. E. A. Ballach, H. H. Barker, C. W. Brown, I. S. Stone, J. Van Rensselaer, J. R. Wellington; ophthalmologist, Dr. C. R. Dufour. The deaconesses, who will also act as nurses, will receive a course of lectures on nursing, to be given by different members of the staff, the details of which are to be arranged by a committee consisting of Drs. Brown, Adams and Street.

**ABOLISH THE DRINKING CUPS.**—Dr. Charles H. Stowell has written a long communication to the *Washington Post*, urging the abolition of the common drinking cup so universal in the public schools. He shows the great possibility of spread, by its use, of contagious and other diseases. He suggests that each pupil carry its own drinking cup.

**OPPOSITION TO MEDICAL PRACTICE LAWS.**—The Eclectic Medical Society of the District of Columbia, which received a charter two years ago from Congress, held a meeting on the 10th inst. and denounced formally the proposed medical laws for the District, on the ground that all further legislation on this subject is unnecessary.

**SMALLPOX IN THE DISTRICT.**—There is a very persistent tendency to the spread of smallpox in the city. While no very large number of cases have so far made their appearance, every little while, despite the strenuous efforts of the Health Department, a new case is discovered and in many instances the cause of contagion is not discoverable. At present every section of the city has its case.

**THE NEW MEDICAL BILL FOR THE DISTRICT.**—The Commissioners gave a hearing on the 11th inst. to a number of medical men representing the Medical Society of the District and the Homeopathic Society, on the various bills now pending before Congress to regulate the practice of medicine. The Commissioners have taken the whole matter under consideration and a report on the subject may be expected very soon. It will pass to the Congressional Committee for final action. Little hope of a law exists, so long as those interested do not agree among themselves and present a plan or bill satisfactory to two or possibly the three schools now existing in the District. The general impression in Congress is that some law is necessary, but the Committee has no time to listen, during a short and busy session, to the wrangles and irreconcilable propositions from the different medical organizations.

**A WASHINGTON DOCTOR IN JAPAN.**—Dr. L. M. Taylor, of Washington, D. C., is in Yokohama, and writing, says among other things: "The general impression here, among intelligent foreigners, is that the Japanese will, before the spring, bring the war to a termination, resulting in their keeping Port Arthur and some additional strategic points captured, China to pay Japan's expenses incurred during the war."

**THE COST OF MAKING ANTITOXIN IN THE DISTRICT.**—Health Officer Woodward appeared before the Commissioners on the 10th inst., and submitted the following estimate for the suppression of contagious diseases: For the production of antitoxin for the treatment of diphtheria—twelve horses at \$40 each, \$480; maintenance of twelve horses at \$10 per month, \$1,200; bacteriologist, \$1,800; materials and apparatus, \$320; total, \$3,800.

**VACCINATION IN THE POLICE DEPARTMENT.**—Maj. W. G. Moore, Chief of the Police Department, has taken action in the smallpox matter by issuing the following order:

"Each and every member of this department will report at his station house on such days and between such hours as may be designated by the surgeons of the District, who will determine whether or not vaccination is necessary in each individual case. Each surgeon will furnish these headquarters with a list of those vaccinated, those not needing vaccination, and any who may refuse the operation, and in due time will report the result to the Major and Superintendent."

**NATIONAL DAIRY UNION.**—The second annual convention of the National Dairy Union is in session here. Among other objects of the Association, they have the establishment of a Dairy Division in the Department of Agriculture.

## THE PUBLIC SERVICES.

**Army Changes.** Official list of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from Jan. 5, 1895, to Jan. 11, 1895.

Capt. WILLIAM C. SHANNON, Asst. Surgeon U. S. A., is granted leave of absence for three months, on surgeon's certificate of disability.

First Lieut. HENRY C. FISHER, Asst. Surgeon, is granted leave of absence for one month.

First Lieut. CHARLES LYNCH, Asst. Surgeon, leave of absence granted is extended one month.

First Lieut. GEORGE D. DE SHON, Asst. Surgeon, will proceed from Ft. Logan, Col., to Ft. Douglas, Utah, and report for temporary duty.

Capt. REUBEN L. ROBERTSON, Asst. Surgeon, leave of absence granted for seven days is extended twenty-one days.

Capt. ADRIAN S. POLHEMUS, Asst. Surgeon, is granted ordinary leave of absence for one month and fourteen days, in addition to the extension of leave of absence granted him on surgeon's certificate of disability.

**Navy Changes.** Changes in the Medical Corps of the U. S. Navy for the week ending Jan. 12, 1895.

Asst. Surgeon AMMEN FARENHOLT, detached from the U. S. R. S. "Vermont," and to Naval Hospital, Norfolk, Va.

Asst. Surgeon C. P. KINDLEBERGER, detached from Naval Laboratory and Department of Instruction, and to the U. S. R. S. "Vermont."

Medical Inspector GEORGE H. COOKE, in addition to present duties, will attend officers on duty at League Island Navy Yard but residing outside of the Yard.

## ADDRESSES.

### RADICALISM AND CONSERVATISM IN GYNECOLOGIC SOCIETIES.

Address delivered at the Annual Meeting of the Chicago Gynecologic Society, October, 1894.

BY F. H. HENROTIN, M.D.  
CHICAGO.

An address by the retiring President seems to be one of the leading features of the annual meeting of this Society, and I see by the program that I am not to be spared this year.

Gynecologic societies are generally organizations of comparatively recent nativity, and are the result of the recognition of gynecology as a distinct and all-important branch of medical science. I am not in possession of facts by which I could outline to you the history of these societies generally, but the work they accomplish is so important that I thought I might entertain you upon their peculiarities and their field of usefulness. Previous to the last two or three decades, the work now accomplished by these associations was made a part of the transactions of the general medical societies, and later on, of the obstetrical societies. As gynecology developed, however, and the womb of alma mater brought into the world the modern aggressive abdominal surgeon, gynecologic societies made their appearance, and to-day they are a factor and a power, whether local, national or international.

The gynecologic society of to-day is usually a select, exclusive, limited and energetic body. The individual in a community who first announces himself as a specialist in the treatment of diseases of women is usually a man who by reason of his ability in that department combined with an appearance, deportment and breeding which commands respect, has been unusually successful; and a society formed around a nucleus of a few such men can hardly help being select. That such a society, select in its membership, should become exclusive and limited is but fitting, and this very limitation makes its members energetic and untiring. Small societies when composed of the right material, constantly surprise us by the character and the amount of good work done.

Among the startling figures in every gynecologic society is the radical. It was probably one or two of these who originated the society itself and who are among its founders or charter members. The radical gynecologist is usually a great fellow. He generally has the best and most remunerative practice in that section of country. His jaw is square and he usually has an opinion, and does not hesitate to give it when requested. In practice he is a "grand *couteau*" and is at his best in abdominal surgery, and when he goes in after something he usually brings it. He generally does but little gynecologic tinkering or

"swabbing" as he calls it; that is, since he has become a radical. He did begin with glycerin tampons, but he has forgotten that. He is, as a rule, a full professor in an undergraduate college unless he has been frozen out by some phase of college politics, and if he is the right sort of a radical, rest assured that no one else teaches that branch in that college.

He is a skillful operator, accustomed to operate before the class, and when he cuts into the bladder or perforates the uterus, usually no one knows of it until it is ascertained if the patient recover. He gets through the abdominal wall in seconds and makes vaginal or abdominal hysterectomies in minutes. He is always a fighter, if a true radical, and ready to take his punishment like a stalwart. Methods differing from his are usually not good methods, and he fights them with knife and pen and tongue. He is, however, a good brave friend and has magnificent courage in proclaiming and maintaining his convictions. When some fellow member writes and reads an article on conservative surgery of pelvic diseases, a strange, far-off look settles in his eyes until the discussion opens. There is much to admire in this man. He gets many hard knocks. The medical practitioner who seldom opens books to read, and never uses a lance, I mean the man practicing medicine with a license and no more, is extremely fond of enlarging upon the present practice of wholesale removal of internal organs by certain men, and when doing so is quite as emphatic and denunciatory as can well be imagined considering their common allegiance to the same profession.

In more moderate terms there come also words of dissent from the youthful and inexperienced. Many of us remember the time when before becoming more expert, we considered radical operations usually unfortunate.

Then again, more serious yet, the general surgeon, and, it may be, a fellow member of the same society must have his say concerning the tendency of modern gynecologists to perform these horribly mutilating operations without reason. The general public also takes up the cry, and the press, or some uninformed unfortunate fellow through the press, dilates upon the butchery and unwarranted license in operating.

All the hot coals kindled by the aforementioned are heaped upon the head of our friend, but he stands bravely to his colors. There is one shaft, however, that wounds him in the most tender spot, and that is the one hurled by one of his own kind beneath the shield of conservatism. An honest radical will stand anything in the way of criticism better than one word from the man who, practicing the most extreme radicalism in surgery is constantly writing and preaching and talking conservatism. When too old to operate, if he does not kill himself by overwork, he sometimes becomes more conservative.

I protest against all these denunciations of the great work being done by these men, and against the unfortunate tendency of some men who write on conservative methods in such a manner as to convey criticism. It was the work of these very men that lifted gynecology far toward its present plane, and in fact, it was the radical procedures that later on rendered conservative methods possible.

That occasionally surgical enthusiasm carries some of these disciples beyond the line of prudence is not denied, but a sin of commission in this respect is not more baneful than one of omission, and on the whole, they usually deserve their reputation. I need not mention names to call to your minds the many men who were persecuted and anathematized for their boldness in the field of gynecic surgery, and yet who are now recognized as having accomplished heroic work in the establishment of the life-saving methods of to-day.

There is an old saying that "Competition is the life of trade." I do not believe it. Whether in trade or in profession, the successful man does his work honestly and perseveringly through his love for his labor and with an honest ambition for success, but without envy for his rivals; profiting it may be by the experience gained from the mistakes of others, but traveling his own road diligently and not striving to pull others down.

In the great struggle for supremacy of these latter days, there is too much of this "knifing," as I might call it. The men at the top are almost constantly at bay. Many of them become unapproachable because of the habit of being perpetually on guard to defend their views. They thus imperceptibly acquire almost vicious dispositions. One man hardly treats Americans with civility, because some Americans have criticized him too harshly. Another does not stir from Philadelphia or Baltimore except in armor clad, for all emergencies prepared, and so on throughout the land, each according to his greatness having a larger or smaller enemy's territory to watch.

These remarks do not apply to proper, just, intelligent and dignified criticism, where such is fit. A deep thrust of a Jaggard blade is frequently quite painful and makes one writhe, but the knife is clean, the wound aseptic, and a veteran is the better for the experience.

All the above I say preparatory to the usual good advice and suggestions of a retiring President, and they come in mind, in view of the constantly increasing evil of criticizing the man in our societies, and forgetting the fact that we are only brothers of one family. Moreover it does not apply to this society more than to many others; though organizations largely composed of men devoted to some special branch are most likely to err in this direction. Allow me, then, to confess some of our sins, and expressing contrition, make resolutions for the future.

Special societies then, being select and limited in membership, should be composed of working members only, and any individual joining but not giving his share of labor, should be allowed to go. Of this there can be no doubt if good is to be accomplished. The gentleman who joins our ranks and makes his appearance once a year or fails to send a paper does not belong with us, no matter how great his name nor how high his standing. The gentleman, also, who appears once a year to read a paper or present an instrument or a specimen, and never comes to

hear any other man's paper or view another man's instrument or specimen, is of very little value as a member, and both of these species should be called to time in a gynecologic society. We will, therefore, pay more attention to attendance at our society in the future, and damned be he who never comes.

We recognize obstetrics as the fountain head from which we sprung, but we acknowledge that we are constantly forgetting our parentage and that we give too little time to its consideration. This is positively a fact. I defy intelligent contradiction to the assertion that apart from the teaching of asepsis, there is more empirical, loose, non-scientific obstetrics practiced in this country to-day than most men would be willing to acknowledge, and even asepsis is used as a cloak to bungling work. This country, with full knowledge of what clean scientific obstetrics means, has done less than any other in rendering that knowledge universal. Concerted action emanating from gynecologic and obstetric societies is most emphatically needed in the regulation of irregular midwifery schools, and in the propagation of scientific midwifery. We will elect as our officers to represent us before the community and in the profession at large, men only who by their good work deserve the distinction and who will not allow politics to creep in our midst.

In our discussions and criticisms we will observe a standard above and beyond all personalities, and be guided by an elevated sense of the dignity of our calling. We will slash without fear the arguments which we believe unsound, and destroy to the utmost all teachings which we consider bad.

Unprepared essays and irresponsible hasty assertions will be expunged from our proceedings and the blue pencil drawn gently through the title: "My last 1,000 hysterectomies," or the photograph of the sort of basin in which to wash the hands preparatory to a laparotomy.

And when a general surgeon in our ranks informs us emphatically that this wholesale sacrifice of uteri must stop, that the history of gynecology in the last ten or twenty years must be written over, we will gently invite him to read us a paper on excision of the malignant parotid and larynx, with statistics, remembering that good breeding will not allow us to notice if the gentleman turns red in the face.

Lastly, as regards the assistance we propose to render to the latest advanced movement in gynecologic circles toward "the Conservative Treatment of Pelvic Intra-abdominal Diseases," we have this to say: We all confess that in our early work we sometimes failed to recognize diseased organs before operating, and we further acknowledge that we sometimes were very little wiser when we had these organs in hand and sight, and that our anxiety to know whether we could exsect such organs safely was greater than our knowledge of what constituted pathologic conditions, and that therefore few of us feel perfectly free from just blame. We state upon honor, however, that since we have learned to distinguish intra-abdominal pelvic disease, we are all conservative and are guided only by one desire; to cure the patient and to cure her permanently and completely.

That we recognize and acknowledge that to radical methods and radical operators is due a large amount of the credit gained by conservative operations later on, and that we have no desire to discredit such gen-

tle men but cheerfully acknowledge their assistance and the value of their labors. We also desire to state that it is our experience that so-called radical operations are very frequently really the most conservative in their ultimate effects, and that these questions are still debatable and will remain so until closer and more frequent and more complete observations help us to reasonable conclusions.

That we believe that all the members of our society and kindred societies are honestly endeavoring to secure the most desirable results, both immediate and ultimate, and that the discreditable work is done by the inexperienced who is honest and conscientious, and the inexperienced who is not conscientious, and that we will do all in our power to assist the one and to disarm the other.

Finally, that we pledge this society as such, in unison with other gynecologic societies, and its members individually, to an honest, earnest and dignified endeavor to promote the aim of all, and that we recognize in our ranks neither radicals nor conservatives, but simply co-workers with one and the same aim—the alleviation of the sufferings of womankind.

### PRESIDENT'S ADDRESS.

Delivered at the opening meeting of the Academy of Medicine,  
Louisville, Ky., Jan. 7, 1894.

BY T. L. McDERMOTT, M.D.

PRESIDENT OF THE ACADEMY OF MEDICINE, LOUISVILLE.

It is a gratifying duty that devolves upon me, to welcome you to these quarters and to inaugurate the opening of the Academy of Medicine. It has long been a matter of unfavorable comment that so prosperous a medical center as this, embracing in its circuit so many luminous votaries, who would add grace and lustre to any sphere, has so long been denied the pleasure and profit that must, of necessity, arise from more intimate communication among its most zealous devotees.

Aside from the fact that such gatherings, not only foster the purest instincts of ethical fraternity but also refine and advance our calling, the mere existence of such an Academy proves the unselfish desire of its founders to strengthen the professional ties that bind us to a lofty purpose, the elevation of our guild and the widening of its beneficent power. What prince or potentate beloved of the populace, has a higher incentive or a nobler aim than we? The glamor of its past has endeared it to every age, and its grander progress in the future will be ended only with the decay of time. From humble beginnings it has traced its prospering presence, through all the years, growing grander in its victorious march at every stage of its eventful career. Nor was its progress made through tortuous channels or by the aid of misleading sophistry. It advanced through broad and open paths that reflected the enlightenment it had gained in its way. Neither the trick of the charlatan, nor the lust of the miser found encouragement or lodgment in the councils of its faithful band. They were always the same brave legion, levying tribute from industry and genius to embellish the temple they were building for the world. A frank and manly army were they that shattered the idols of fraud and turned the heedless ear to the alluring temptations of princely influence or debasing gold. The crown won by those humane apostles of science by means of such sacrifice and devotion

has been transmitted to us, and through us, to posterity; and I hope we are erecting a sanctuary where fitting proselytes may be dedicated to the noble task of carrying us forward to greater victories and grander trophies.

While a well poised modesty might forbid any rash expectancy, who can tell but that from our humble midst some brilliant star may yet illumine paths that are still dark, and that yet may open glorious vistas unimagined in our brightest dreams? From less promising beginnings men and measures have risen into exalted prominence and have brightened the pages of history with their renown.

I hope this meeting will be the forerunner of a long and intimate companionship, embittered by no envious rivalry, or selfishly sought prominence. I hope it will be the personal aim of all to extend and perpetuate the usefulness of this association; for in no other calling is there so often need of a helping hand and of charitable counsel. Give lavishly of both to the aspiring and the humble, for the general good is only attained by common effort and self-abnegation. In every city of considerable size in the world, a society like this has been the Mecca and the inspiration of the proudest exponents of our science.

Forbearance toward the frailties we all possess and a zealous enthusiasm for the common good are the cardinal elements of success in this undertaking. Every individual member must feel that upon his efforts largely rests the usefulness of the society. We start the enterprise to-night in a general way. It depends upon the majority of the body to guide our steps in the future into such paths as may seem most desirable for the general welfare. It is intended that these quarters shall be kept open daily and that they shall be supplied with all the latest periodicals. It is hoped that the members will avail themselves of this opportunity to cultivate each other and to study together. In a long experience as a student and practitioner, I have realized that the most valuable lessons to me, were those I learned by contact with fellow doctors. The benefits resulting from quick and constant relations with other men in the same pursuits as our own are inestimable, whether at the bedside, or on the rostrum. A consultation in either case, not only decides the hesitating but confirms the established opinion. Those who have sometimes wavered in momentous dilemmas can tell how grateful they were to a helpful brother whose sturdy skill gave them medical guidance, or whose masterful poise in a fateful moment checked the rashness which might have jeopardized a precious life.

The Academy is especially intended for the encouragement and development of the younger members of the profession; and it is hoped they will excite and emulate the generous rivalry that intellectual efforts stimulate and improve. To them must we look for that breezy personality that gives vigor and freshness to an enterprise whose vitality so largely depends on an active and eager membership. It should be the duty of all to maintain that benevolent harmony, without which existence, if possible, would only be characterless and without profit or pleasure. Let it be the unwritten law of the assemblies that captious criticism, acrimonious debate or selfish display shall beget silent scorn rather than generous tolerance. No acerbities must be allowed to mar the peaceful haven we have designed for our exploits

We have no need for warriors or their methods in this Arcadian realm where we hope the white-winged messengers of peace and forbearance will insure a long and honorable prosperity. Rather let us emulate the busy bee, whose quiet but indefatigable industry slowly but surely achieves results that furnish the text for the grandest ambition. Nothing is accomplished in scientific circles by the lash or the sword. Patient delving, silent study, harmonious communion and comparisons with fellow-laborers are the omnipotent factors that build and ornament the fabric whose foundations are built on stony facts and gilded with empyrean truths. The real architects of the world are brain-workers. In the little gray cells are evolved the masterful conceptions before which the brawny mason and the iron-monger stand in awe while realizing the insignificance of their own rude works. Franklin harnessing the lightning, Morton evolving an anesthetic, Jenner elucidating vaccinia, these are only a few of many instances I might cite to show the tremendous value and glory of mental achievements before which the brutal deeds of giants, the bloody triumphs of armies and the huge works of ponderous machinery pale their fitful luster as ignominiously as a flickering taper in the glare of day. Mind dominates matter, and the wise physician, figuratively speaking, controls the dynasty of every kingdom.

How few, even of our own number, realize the stupendous power of an alchemy or a knife that may blast a nation's hopes or break a mother's heart. Only after a lifetime of ineffectual labor is drawing to its close, does the sluggard comprehend the loss in his wasted moments or even the jaded savant, while realizing his incompetence give utterance to his impotent regrets. A song of praise or a meed of opulence may beguile us with their tuneful lullabies and may seduce the loitering dreamer while time and opportunity are running riotously away. So life, like the brook, flows on and on, and the dalliance of the year that has passed becomes the anathema of the one that is born, without relief from the curse that has blackened them all. Toward the end, prizes and power alike have exhausted their potency; and still the sluggish mill pond contains the sediment of a myriad aspirations that sparkled like iridescent diamonds in the crystal waters at their source. Only to those patient few who show untiring fidelity to their work and a lifelong devotion to duty, will come the real meed of glory. By many unostentatious sacrifices they may reach a pinnacle for others' wonder, may build an immortal monument for themselves, while giving health and happiness to untold millions. The lesson of a self-sacrificing life is not lost. Even moderate intellectual powers, rightly applied, may bring us greater rewards than riches or rank, though they also can be won. To many of us belong such intellectual attributes and powers. What tocsin shall wake them from their slumberous lethargy?

"Lives of great men all remind us,  
We can make our lives sublime."

But how or when? That is the burning question which glows in the morning of intention, but the night shades of delay enshroud them in their pall. The enigma finds solution in the gathering of this evening, the clash of intellect in seemingly debate encompasses the defeat of error, and as the sword in battle leaves only the imperishable to valor. Out of the destruc-

tion comes conquest, and truth and fame are the rewards of the struggle. Let us cultivate these discussions then, in the spirit in which they are instituted, for self-improvement and the advancement of medical research, always keeping in mind the axiom; that in "unity there is strength" and that the end to be attained is the common good of all. Let us not imagine for an instant that any individual member of this society is essential to its future welfare. Egotism and contention are a baleful menace to our prosperous continuance. Our association must be harmonious to be stable. Let the suave chivalry and the courtly demeanor of the drawing-room add lustre to the learning and skill of the polished doctor and let the wounds of debate be forgotten at their close. Recriminations inadmissible in convivial society should find even less tolerance in the efforts of scientific explorers. Let the torrid Hotspur bathe his reeking flanks in patience and accord forgiveness to petulant zeal, always remembering the object of our meeting is to promote medical study for the enlightenment of our guild. This is our professional home. Beneath its shelter we can all find a warm welcome and a pleasing habitation. Let the discordant sounds that shock men in the busier marts of trade find no echo in its precincts, hallowed by so many associations and sacred to such lofty themes. Within the walls of a symposium so alluring, let the traveler of science find fitting respite and a sweet hospitality in the bosom of his friends. Surrounded as I am, in this charmed circle by men I know so well, it seems superfluous to mellow the lute to ears properly attuned by study and breeding; but I feel we have set in motion a beautiful engine, capable of doing great good for us and afflicted humanity, and I would be derelict in duty to hush these notes of warning.

On the other hand, if we realize the advantages as well as the dangers that confront us, we shall succeed in the fullest measure. This society will be a beacon to all. Let its shining light not only illuminate our own lives, but guide others who are in darker lines to its fostering influences. Thus educated and equipped it may be our boast, as it has been our predecessors, that our great brotherhood has been ennobled by every generation that wore its livery.

## ORIGINAL ARTICLES.

### ON A NEW TYPE OF NEURASTHENIC DISORDER—ANGIO-PARALYTIC OR "PULSATING" NEURASTHENIA.

BY CHARLES L. DANA, M.D.

PROFESSOR OF NERVOUS AND MENTAL DISEASES, NEW YORK POST-GRADUATE MEDICAL SCHOOL; VISITING PHYSICIAN TO BELLEVUE HOSPITAL.  
NEW YORK.

The present tendency to analysis and differentiation of clinical types is a helpful one. It may at first sight seem to encumber our nosology needlessly, but the final result is to secure a better comprehension of disease, its cause and its treatment, as well as to lead eventually to simpler classifications. This fact has been well illustrated in the history of neurology. I feel sure that the differentiation of a good many types of neurasthenic disorder will eventually be made and that this, if carefully done, will help to remove the indefiniteness at present suggested to our minds by the word.

Such is my apology for attempting to describe a new type of neurasthenic disorder now.

I have had six patients who all presented very distinct and peculiar symptoms. Coming to me at varying intervals I have been struck with the similarity of their symptoms. It justifies me in claiming for them a distinct type of functional disorder.

The clinical portion is best shown by telling the story of one of my patients:

*Case 1.*—He was a furrier by trade, an Englishman by birth, married, and 29 years of age; his mother had heart disease; the rest of the family were healthy. He was always a strong and active, though nervous, young man. Since a boy he had used tobacco excessively and drank much beer. He had never had syphilis or bad sexual habits. When he was 18 years old he was attacked with a sudden fainting spell, and a few days later he had something like a convulsive tremor. The seizures were evidently due to excessive smoking. Since these attacks, which did not recur, he has had a general feeling of pulsation through the whole body. It is not his heart alone but his chest, trunk and head that throb in unison with the heart beat. This pulsation stays with him day and night, and in every position of the body. Neither rest or activity modifies it very much. Abstinence from tobacco and alcohol does not relieve it. It is accompanied with some nervousness, and he occasionally has a sense of propulsion as though he were going to run forward. He has very rarely vertigo but no tinnitus aurium. He sleeps well. His symptoms have continued, with varying intensity, up to the present time. He is now, however, rather worse. An examination of him reveals a healthy, nervous looking man; the hands show a fine tremor. The skin is dermatographic, to such an extent that one can distinctly write a name on it which comes out bright and red and remains for thirty or forty minutes. The skin is moist and ruddy, the pulse very soft, compressible, the rate being 80 per minute.

There is no goitre or exophthalmos. He sometimes has a little vertigo; but no pain, or headaches. His special and general sensations are normal. He has no atrophy or paralysis. There is some exaggeration of the knee-jerks and a considerable degree of the static ataxia which I find common in neurasthenics. His urine is normal. His heart is normal, beating strongly, yet it is not hypertrophied. There are no murmurs. Pulse, 75. He has a decided epigastric pulsation and a systolic murmur is heard here. Pressing on the carotids lessens quickly the throbbing feeling in his head.

The trouble makes him nervous and distressed, and he is barely able to attend to his business. A long rest, including a sea voyage, and abstention from tobacco and alcohol did him no good.

Under treatment he improved slowly. Two years later I saw him again. His health was much improved but the pulsation still annoyed him.

*Case 2.*—The second case was more remarkable by reason of the successful therapeutic procedure employed. The patient was a man 27 years old, single, an oysteropeener and dealer by trade. He had worked very hard and been exposed to wet and cold. He denied, absolutely, sexual excess and venereal disease. He used alcohol and tobacco in moderation. It is to be remembered, however, that assertions of temperance in these things are not always trustworthy; and in this patient I thoroughly suspected masturbation. His parents had no nervous trouble. He had had most of the diseases of childhood, but was always fairly well aside from these. In 1884 he had typhoid fever. In May, 1889, he suddenly and without known cause, began to have attacks of palpitation of the heart. This gradually passed into a condition in which he felt a sensation of pulsation all over the body; a general throbbing, synchronous with the heart beat. This beating was much more marked in the head and was here accompanied with a feeling of pressure in the occipital region. He suffered a great deal from cold hands and feet. He had no dyspnea and no pain. His appetite and digestion continued fairly good but he became very nervous and mentally depressed; and his sleep was disturbed. In fact he denied that he slept at all. I first saw him in March, 1890, a year after his trouble began. Examination at this time was largely negative, so far as objective symptoms are concerned. He was fairly nourished but rather thin. The lungs and abdominal viscera were normal. The heart action was not strong, but there was no dilation or murmur. The rhythm was normal, and the pulse rate never high, ranging from 70 to 80. The pulse was very soft and of low tension, the hands and feet cold and easily congested. The skin

was very dermatographic, a mark upon it lasting five hours. He had an epigastric pulsation. Pressure on the carotid stopped the beating on the side of the head on which pressure was made. There was a slight enlargement of the thyroid, but no exophthalmos, no tremor, no sweatings, no heat sensations. The reflexes and the special senses were normal. The urine also was normal in amount and reaction: specific gravity 1026. It showed great excess of phosphates. His intelligence was good; he was not hysterical. No form of treatment, mental or medical did him any good. He had given up work because he said he could not attend to it.

I finally sent him to the hospital and had him put to bed and carefully watched for possible masturbation element. Rest, carotid compression, tonics, sedatives, ergot, digitalis and other drugs failed to relieve him except that his sleep was improved by sulphonal.

He became willing to undertake any treatment for his relief, and I finally sent him to Dr. Seneca D. Powell who kindly undertook to tie the common carotid. This was successfully done at the Post-Graduate Hospital in the fall of 1890. After the operation the patient expressed himself as quite rid of the distressing beating so far as the right side of the head and body was concerned. He felt so much relief that he was able to endure the left-sided beating. He left the hospital and went to work. Dr. Powell and myself have seen him at intervals since. He continues better; the beating has not returned on the right side but continues on the left. He has gained some in flesh and strength and is comparatively comfortable, it being now over three years since the operation.

*Case 3.*—The patient was a young man of 25, of healthy antecedents. He denied venereal infection. He was always of a nervous temperament. For the past three years he had drank excessive amounts of beer, had sometimes taken a small keg in a day. He smoked moderately and there was no sexual excess. In the spring of 1894, while in apparent health, he awoke one morning with a feeling of dizziness and nervousness; sensations of beating and throbbing appeared; he became very nervous and depressed and was unable to concentrate his mind on his work. A beating sensation was felt in his head and chest continually and caused him great distress. He had also headache and insomnia, and ringing in the ears. He placed himself under the treatment of a local physician who found a sensitive urethra and treated him a long time for this with slight benefit. When examined by me, I found a rather rapid pulse, 85 per minute, of low tension. The heart was normal in size and sounds, the peripheral circulation was sluggish, the extremities cold and easily congested; the skin was dermatographic; there was an epigastric pulsation, though not so marked as in other cases. An examination of the eyes by Dr. Wm. F. Mittendorf showed astigmatism and a slight venous pulsation of the retinal vessels. The tongue was coated and the bowels constipated. His most annoying symptoms were the beating, the nervous depression and that indescribable feeling of incapacity to work and enjoy life which the neurasthenic dwells upon so much. I should add that he had repeatedly tried to master his sensations and go to work, but they never left him, and he returned to his invalid habits in despair. He has improved considerably, but is still far from well.

I have not met with exactly similar cases in women.

*Case 4.*—A married woman, aged 55, and several years past the menopause, has frequently complained of the same pulsating sensation. She is rather large and plethoric, and is of a nervous temperament. For several years she has suffered from nervousness, insomnia and the vasomotor symptoms of the climacteric. She now complains chiefly of the constant "beating, beating, beating" in the head and chest, and is quite sure a vessel will burst unless it is stopped. The pulse is quite regular, constantly at 100, but there is absolutely no exophthalmos, goitre or even tremor. Basedow's disease does not appear at this age. Her heart is slightly enlarged, and there is a systolic murmur at the base, which, however, disappears when she gets relieved by treatment of the tachycardia and pulsation. The urine is normal. She improves rapidly under aconitia and rest. The pulse got down to normal, the murmur disappeared and she was comparatively well for six months. The symptoms returned for a few months under stress of some domestic affliction and have been again relieved.

It is evident that cases of this kind are more closely related to Basedow's disease than those before

described. They are not due to any heart lesion, for people with heart disease do not have such pulsating phenomena except during attacks of palpitation.

The other cases which I have seen have not all been so severe and obstinate as the above four, but the patients have shown the low tension pulse, vasomotor weakness of extremities, subjective sense of beating felt most in the head, epigastric pulse, dermatographic skin, insomnia, nervousness and mental depression.

*Etiology.*—So far as my experience goes, the cases occur in young men or adults under 40. I have not seen this form of disorder in women except in the modified type described. The abuse of tobacco and alcohol, particularly the former, was the conspicuous exciting cause in two cases, while tobacco and alcohol and sexual excesses were factors in the others.

*Pathology.*—The instability of the vasomotor system in neurasthenics is well known and has been particularly shown by Wolf (*Allg. Zeitsch. f. Psych.* xxiv.) and Anjel (*Arch. f. Psych.* viii., 2). The special symptoms of palpitation, of epigastric pulse and of tinnitus, fullness of the head, head pressure and throbbing are also familiar. But the patients I describe have more than this. There is a general pulsation of the body felt most annoyingly in the head but also in the trunk. One patient (Case 2), when suspended in a Sayre's apparatus, could be distinctly seen to move with each beat of the heart.

It appears to me that in this condition there is an abnormal relaxation of the arterioles and capillaries, the blood is thrown into tubes that have lost their resiliency and thus the pulse waves are not fused together. It is as though a liquid were thrown through a series of tubes with flabby non-elastic walls. Hence the heart-beat is strongly felt all along their course as far as the capillaries. Besides this there is after a time a hypochondriacal element in their cases. The patient's attention becomes fixed unalterably on his sensations.

Van Hósslein (*Miller's Handbuch der Neurasthenie*, p. 127) describes the case of a neurasthenic who suffered from epigastric pulsation. This tormented him so that he went to a surgeon who opened the abdomen thinking he had an aneurysm. The abdominal aorta was found to be perfectly normal; the wound healed and the patient was cured.

I doubt if Dr. Powell's success can be accounted for in this way, because he only cured one side of the man. Yet it seemed to help him generally and permanently more than one would expect from the nature of the operation.

*Symptoms and Diagnosis.*—I have already referred to the characteristic symptoms of the malady. The patient is neurasthenic and presents the general symptoms of this condition. But his special symptom is the sense of beating of which he never loses the consciousness. He has a low tension pulse of normal or but slightly accelerated rhythm; he does not have palpitations occurring in paroxysms as in Basedow's disease. He may or may not have tremor; there is a striking degree of dermatography, and an epigastric pulsation. Pressure on the carotid stops the beating on the corresponding side of the head. There is no evidence of exophthalmic goitre. There is, usually, insomnia, nervousness and mental depression.

*Treatment.*—The striking success of surgical treatment in one case leads me to believe that ligation of

an artery is the surest cure for the disorder. Still in the milder and less typical forms, cure is obtained by the use of general and vasomotor tonics, in other words by the ordinary treatment for neurasthenia. I have found no benefit from ergot. Restrictions must be promptly placed upon the use of tobacco, alcohol and sexual indulgence. Potassium iodid, hyocine, hydriodic acid and arsenic sometimes act well in this as in other forms of vasomotor neuroses. Aconitia in doses of gr. 1-200 may be of service. I strongly advise against the use of the bicycle in these cases.

A prescription containing bromid of iron gr.  $\frac{1}{2}$ , bromid of potassium grs. x, hydrobromic acid  $\mathfrak{m}$  viii and spartein sulphate gr.  $\frac{1}{3}$ , gives relief in many cases. Bromid of camphor and strychnia are often useful. I insist, when possible, upon the patient taking hydrotherapy in the form of a Charcot or Scottish douche.

50 West Forty-sixth Street.

### A FURTHER DISCUSSION ON MALARIA A WATERBORNE DISEASE.

Read before the Mississippi Valley Medical Association at its twentieth annual meeting, at Hot Springs, Ark., Nov. 20, to 23, 1894.

BY W. H. DALY, M.D.

PITTSBURG, PA.

Ex-President of the Section of Laryngology of the Ninth International Medical Congress; Member of the American Climatological Association; Member of the American Laryngological Association; Senior Physician to the Western Pennsylvania Hospital, Pittsburg, Pa.; Consulting Physician, Throat Department, Pittsburg Free Dispensary; Member of the British Medical Association.

A paper which I read before the American Climatological Association, in Washington, May 29, 1894, entitled, "Some Practical Observations on so-called Malaria being a Waterborne Disease," and published in the *Medical Record* of Sept. 15, 1894, has called forth in the *Medical Record*, and other medical journals, much correspondence pro and con; it has also brought to me many private letters from prominent medical men, who have read my paper, many, in fact most of them, not only indorsing my observations and views, but giving as a result of their own independent observations, data which strengthen the position I have been brought to contend for. I am pleased to learn of the widespread attention the paper has received, and only ask that the same unprejudiced observations will be resorted to that my paper comprehended, that every factor in the question shall be taken account of, and that causes and consequences shall be followed up, in considering both the evidence of the water, being the sole or chief vehicle of the Laveran corpuscle passing into the human organism, or the air we breathe, or whether both the air and water are the efficient vehicles of the germ finding its way into the blood, where we know it exists in the pathology of malaria; producing its manifestations, known to us as paludal fever, malarial fever, or chills and fever in its multiforms.

In summing up the evidence in a given case of so-called malaria, it is important to remember, that the water vehicles of malaria may include contaminated land water, taken into the stomach on the stalks of celery, or on the leaves of lettuce, or it may find its vehicle in the rinsing of milk cans with malarial water, or in the adulteration of milk with contaminated water containing the Laveran germ; the cistern water stored under the earth may easily be contaminated by the earth water containing the germ, if the

cistern itself is cracked or otherwise inefficient; the fact that the patient has drank at all of suspected water, even but once, ought to be taken into consideration, as the single draught of contaminated water may have contained all the necessary germs for the infection of the blood and the production of the fever.

It can well be understood how the greatest care must be exercised in a malarial country to avoid taking into the stomach, some time or other, the germ in drinking water, and it will therefore appear at once, how necessary it is to exclude the water possibility, in making up data that will exclude the air theory of infection.

In order to define my position on this question, permit me to quote from my article in the *New York Medical Record*, of Sept. 15, 1894, wherein I say: "Twenty years' observations and studies on this subject, and investigations made in various districts from Manitoba to Louisiana, and all along the southern coast of the Atlantic Ocean, and of Cuba, Yucatan, and other districts in Mexico, lead the writer to the conclusion, that so-called malarial disease is not easily, if at all, contracted by inhaling so-called malaria or bad air, of the low, swampy, or new lands, but it is distinctly, if not *almost exclusively*, due to drinking the water that has come into contact with, and become infected with, the malarial germs or infusoria that exist in the earth and waters of the swamp and lowlands. This germ does not ordinarily, if at all, float in the air during the day, nor does it find easily a vehicle in the fog or vapors of the night. Indeed it is difficult to understand how one is to avoid the night air, even if it is conceded to be deleterious—a conclusion I much doubt. Does any other air than night air exist at night? Is it possible to breathe any other? Is there any habitation sufficiently sealed against the outside air, to make the breathing of outside night air impossible?" It is the water alone that can and must be avoided; to avoid the air is quite impossible.

Touching the important general question of malaria, it is pertinent to quote from a recent review in the *British Medical Journal* of Oct. 27, 1894, of Dr. A. Laveran's work on "Paludism," as translated by Dr. J. W. Martin, of London, and printed by the New Sydenham Society for 1893. The review says: "It is interesting to note the different ways in which two of the most important discoveries in pathology of modern times have been received. No sooner had Koch proclaimed the bacillus tuberculosis, than it was accepted with acclamation on all hands, immediately stamped as genuine, and passed as good current coin. This was in 1882. Two years before this date, in 1880, Laveran described the microörganism of malaria. The discovery was hardly recognized at the time, and even now, after a lapse of thirteen years, it excites so little interest that many are unaware that it has been made. The pathogenetic character of the schizomycetes (fungus or bacteria microbes) as a class had been well established long before Koch made his famous discovery, but no one suspected that an equally if not more important rôle is played by the protozoa (unicellular animals) as disease agents, until Laveran made his discovery. If we look at the matter from the practical point of view of sickness and mortality, we find that bacillus tuberculosis is credited with one-seventh part of the total mortality of mankind; the malarial organism with one-half.

"For thirteen years the great discovery has been before the profession, and yet practically nothing, so far as Englishmen or Americans either, excepting Sternberg and a few others are concerned, has been done with it. We should like to know what practical teaching in the matter there is in our medical schools, particularly in our naval and military medical educational establishments. We wonder how many of the men whose principal future lifework will lie in combating this organism have been brought face to face with the thing itself, have actually seen their future enemy, or been taught how to search for it. In this matter our medical guides and teachers, both in this country and even in France itself, have a great deal to answer for. But signs of the recognition of the importance of Laveran's work are beginning to be discoverable. Evidence of this we have in the translation recently issued by the New Sydenham Society. We trust that this semi-official stamp of recognition will at last insure its general acceptance by our countrymen, or, at all events, its thorough investigation.

"Dr. Laveran's work is a very complete, temperate and judicial statement of all the more important modern views on the subject of the malaria parasite. In the course of the work the parasite in its polymorphic forms is carefully described; its bearing on the pathology of malarial disease and the practical outcome of our knowledge of the existence of such an organism are thoroughly discussed. Interesting chapters call attention to similar forms of parasitism among the lower animals, and detailed clinical evidence is given in abundance in support of many of the statements the author advances. Dr. Laveran expends a good many pages, we think unnecessarily, in defending himself from the repeated attempts which certain Italian investigators have made, to filch from him the credit of a certain and important part of his great discovery. Any one who has read his first large work and his numerous early papers knows very well with whom the entire merit of the discovery rests. Although stating them very fully, Laveran does not see his way to accept Golgi's views of the life cycle of the plasmodium, fascinating and original though they may be."

While the great question of malarial fever is one of widespread interest, it is the one phase of it that the writer is investigating, viz.: The waterborne means of infection. Laveran says:<sup>1</sup> "Numerous facts tend to prove that the infection may take place through drinking water, and that persons who have contracted paludism (malarial fever) have almost always made use of water of palustral (with humid or marshy soil) localities." He says further:

1. "It has been found repeatedly that in the same localities, among persons living under the same conditions, but drinking water from different sources, some were attacked by palustral fever while others escaped.

2. "In certain localities which were formerly insalubrious it has been sufficient to place pure water at the disposal of the inhabitants, instead of the stagnant water which was formerly used, for palustral fevers to disappear.

3. "In some localities, otherwise very healthy, people may contract fever, whose drinking water comes from unhealthy localities, and the persons most ex-

<sup>1</sup> Paludism. By A. Laveran. New Sydenham Society, published 1893.

posed to infection in these conditions are those who consumed most water.

4. "Travelers passing through unhealthy countries often succeeded in escaping fevers, by only drinking water that has been boiled, while people who do not take that precaution suffer severely."

Dr. Norbury<sup>2</sup> in the *Medical Record* of Oct. 6, 1894, says on the subject of "Malaria a Waterborne Disease:" "I wish to add my experience and observation to the line of inquiry pursued by Dr. W. H. Daly, of Pittsburg, Pa., in his most excellent paper in the *Medical Record* of Sept. 15, 1894, regarding malarial infection. In the summer of 1881, while employed under the directions of Maj. G. J. Lydecker, U. S. A., in the construction of the Kamps-ville Lock (Illinois River improvement), Kamps-ville, Calhoun County, Ill., I had the occasion to observe the effects of drinking water on persons temporarily residing in this malarial district, as well as upon the native inhabitants. The land immediately adjacent to the lock site was known as bottom land—it was overflowed at each high water season—and was poorly drained, being very flat. Water stood in the bogs or swamps until the dry weather of summer had completely evaporated it. Drinking water was obtained for the men employed in the construction of the lock foundations from drive wells, put down to the depth of twelve or fifteen feet. The men employed on the dredge and tow boats and the officers used filtered river water.

"Among the many laborers who sought employment were forty Swedes, who had arrived in this country from their native land about ten days before coming to the lock; they were a vigorous, well-nourished body of men, eager for work. They took board in quarters near the lock, and drank water from the drive well. Within ten days one of them was taken down with malaria, and before two weeks ten or more had succumbed; one died and two were seriously ill. At the end of a month but three were able to continue work; one of these had no malarial symptoms at all; he worked on one of the boats, where he drank filtered water. Now all of these men seemed peculiarly susceptible to malarial infection, and as quickly as they could returned to Chicago to escape its ravages. The men who worked on the boats escaped the disease. The natives who drank of the well water were not so much affected, yet quite a number of them had to quit work. The wells used by the natives, however, were located on the edge of the bluffs, about one-half mile from the river. Here we have, I think, marked evidence of the infection coming from drinking water; for all the employes, officers and all, were situated under like atmospheric conditions and exposed to the same heat, etc., during the day, yet those who used filtered river water escaped, while those using drive or open well water were afflicted. Some three and one-half years spent in engineering work on the Illinois River confirmed my belief in the possibilities of infection from water supply, rather than from atmospheric conditions. I indorse Dr. Daly's views."

Since my paper appeared, Dr. Healy in a letter to the *Record*, asks some pertinent questions as to a solution of an outbreak of malaria some four months ago in the Twenty-fourth Ward, New York City, following the excavation for sewers, that can only be answered by a careful investigation on the ground, as to whether any of the persons taken ill: 1, had drank from wells;

2, had eaten lettuce, celery or other uncooked vegetables from paludal localities; 3, whether any had drank milk from paludal localities where the cans may have been rinsed, or milk adulterated with palustral water (malarial).

Dr. Healy, however, says as to the drinking of contaminated water, being one of the prime factors: "I can offer proof positive in the person of myself. Some eight years ago the house in which I then resided, had for its water supply a cistern and a well. After using this well water for drinking purposes for a few months I suffered from a severe attack of chills and fever. Upon investigation I found the well was receiving the leakage from an out-house as well as the surface drainage. Upon discontinuing its use all symptoms disappeared."

Dr. R. D. Jewett, editor of the *North Carolina Medical Journal*, writes me in a private letter dated Oct. 22, 1894: "Your ideas are emphatically ours, and we believe that acceptance of this fact by our people will be a great boon to this section." And Dr. Jewett has in these few lines, the gist and great good of the whole question, viz., teach the people to drink only uncontaminated water, and you have made the great advance toward settling this question. And this is the chief end and aim of my several papers; for the accomplishment of that custom will go far toward settling the question of how we are to prevent palustral fever, by eliminating what I believe to be *quasi* factors.

Dr. M. D. Hoge, Jr., of Richmond, Va., writes me in a private letter dated Sept. 19, 1894, as follows: "Your 'Observations on Malaria' in the last number of the *Medical Record* is one of the cleverest and most satisfactory articles on the subject I have ever read. I write to thank you for it, as a believer in your views for a long time past. To my mind it is the only rational and reconcilable theory on observations on this plague of our section. I am at present engaged in a study of the blood of cattle suffering from climatic fever, and hope to have something ready in a short while."

Dr. W. A. Plecker, of Hampton, Va., writes me in a private letter dated Sept. 18, 1894:

"I am convinced that you are correct in your views, and am surprised that attention has not been more generally called to impure water as a source of malarial fever."

I have received many other letters of a similar tone, and there can be no doubt that it is the duty of the profession to cultivate a habit in their patients to drink only boiled or uncontaminated water in infected districts; since they can not avoid breathing the suspected air let us at least eliminate the water factor. I confidently predict we will then have successfully compassed the prevention of palustral (malarial) fever.

We all fully agree with Laveran's researches, and it is quite well known to all my hearers that damp, uncultivated, marshy or humid soils are those that offer the best medium for paludism. The existence, however, of marshes properly speaking is not necessary, and on the other hand all marshes do not cause fever, even in hot countries; at Tahiti in Australia and New Caledonia, both of which abound in marshes, palustral (malarial) fever is rare. If the marsh then is not necessary there must be a humid soil for the Laveran corpuscle to propagate itself. The small rains which take place at the end of the summer in

hot countries, and which are soon dried up with the sun, are known to be very dangerous and productive of palustral (malarial) fevers. This fact has been observed by Dr. W. J. Lumsden, Dr. Oscar McMullen and others of Elizabeth City, N. C., who write me, saying, especially are these rains productive of new cases, as well as outbreaks of fever in old cases, among those who have drunk the water from surface wells, and the same facts are spoken of by Laveran and other observers.

The physical conditions here are evidently hot sun, brief fall of storm water, succeeded by hot sun, for the rapid growth and development of the paludal parasite; a long-continued rain, followed by colder weather are conditions unfavorable to development, as shown by the lesser multiplication of palustral disease.

There can be no doubt that the digestive juices are destructive to the palustral protozoa in the stomach, if the digestion is strong and healthful, but that condition, unfortunately, is not an ever present condition in those who drink water from palustral soil. Hence those who are most readily affected are such as are fatigued, weak, or under mental or physical strain or disease; anemia and privation also weaken the digestive vitality, and permit the passage of the parasite, through the diluted juices of the stomach into the blood. It has been so often demonstrated, as to be accepted as a fact, that parasites are developed by preference in weakened constitutions, where vitality is already lowered, just as mosses and lichens invade the trunks of sickly trees and other vegetable growths.

"It seems," says Pasteur, "that vigorous life repels other life which wishes to graft itself upon it. It is when an individual grows weak that it becomes an easy prey to the parasites which besiege it, and it has been shown that by starving animals they can be made liable to disease, which they resist in their normal state.

"The period of incubation or latent stage of palustral (malarial) fever has been shown to be from seven to nine days, and the longest period seventeen years (latter problematical), and Mariotti and Ciarocchi, Cella and Marchiafava, Gualdi and Antolisei, and Angelini, made experiments which showed that, when palustral blood containing hematozoa is injected into the blood of man free from paludism (malaria), the fever appears in the inoculated subject on an average of ten days after the injection.

"The paludal hematozoa (malarial) in the blood live at the expense of the normal elements of it. The invaded red corpuscles grow paler and paler in proportion as the parasite develops, and it is probable that no anemia, except that resulting from hemorrhage, can be better explained than palustral anemia."

Professor Bouchard writes: "One thing seems certain to me, viz., it is that bacteria act in animals by the matters they secrete, and further, the fever of the infectious disease is toxic; it is provoked by diastases, such as that studied by Roux; by ptomaines, such as the amidaleine of Brieger."

A recent private letter from Dr. A. Laveran, of Paris, says:

"*My Dear Confrere*:—I thank you very sincerely for your article, which I have read with a great deal of interest. I think with you, that palustral infection has its place in water, and I am happy to see your new work which sustains that view. One finds, moreover, in the water of palustral

localities, organisms, very closely resembling the hematozoa of palustræ, but no one has yet succeeded in proving the question, as to the form under which hematozoa is to be found in the medium outside of it.

Be pleased to accept, my dear confrere, this expression of my devoted sentiments."

I have made some unavoidable digressions in discussing the phase of this subject in which I am deeply interested, and have taken the liberty of quoting liberally from Laveran and others in the foregoing pages. It is within the easy province of every medical man to make researches on this question, unprejudiced by any theory, and as a practical means of testing the drinking water factor in paludal infection of the system. Let every physician and citizen in infected regions resolve to observe and advise the drinking of carefully stored storm water in cisterns above ground, and the boiling of land water, where such must by force of circumstances be used for potation.

## ON THE VALUE OF KINESITHERAPY IN GYNECOLOGIC PRACTICE.

Read before the Gynecological Society of Boston.

BY RICH HOGNER, M.D.

BOSTON, MASS.

The Swedish medical gymnastic was founded, developed and perfected, as is well known, in the beginning of this century by P. H. Ling, and to-day there is not a civilized country where its fame has not spread and where some medical gymnast has not located.

That the Swedish medical gymnastic is firmly grounded on scientific principles is best shown by the fact that regular physicians are beginning to take it up, as a specialty, more and more, and that the public has confidence in its ability in spite of the damaging influence of the so-called massagists, hardly half taught or self-made medical gymnasts, not to mention ignorant male and female administrators of baths, who do all that is possible to disgrace the name and drag down the method. But just as "wise old crones" and midwives have not been able to injure the scientific practice of gynecology and obstetrics, so have their counterparts in the field of medical gymnastics been unable to drag down the kinesitherapy. The labor of these impostors has created a wide gulf between the quack and regular medical gymnast, a gulf which will be widened still more in proportion as physicians study and themselves practice the manual treatment of diseases.

Swedish medical gymnastics reach the desired results by means of active and passive movements, increasing or decreasing the metabolism, regulating resorption in any given part of the body and by in-

creasing the general tone. Kneading and other manipulations quicken a sluggish circulation, increase the blood supply and local nutrition, and by this means tone up the vessels, nerves, muscles and elastic tissues. In case of great nervous irritability it has a tranquillizing effect. Its proper practice requires an intelligent knowledge of anatomy and physiology, and for the best results a thorough medical education. There are, however, comparatively few physicians who devote themselves exclusively to kinesitherapy, but, on the other hand, there are many skilful, experienced medical gymnasts (especially in Sweden, where they must go through a three years' course of study), whose great daily experience is productive of many facts applicable to new fields of investigation. The good results obtained by these medical gymnasts in treating diseases which many physicians have looked upon as of the *noli me tangere* sort have, therefore, been doubtfully received in the beginning and indeed reasoned away entirely, until some physician of known authority has been sufficiently unprejudiced to test the matter himself and find the cause—previously shrouded in darkness—for the wonderful cures which have, in fact, been made by many medical gymnasts; similarly has been the experience of kinesitherapy in gynecologic practice.

As long ago as 1859, a Swedish officer and medical gymnast by the name of Thure Brandt, employed Swedish medical gymnastics in the treatment of the so-called female diseases, but not till 1877 had this empiric perfected his method. For many years the fame of Brandt's cures had spread abroad, but physicians and gynecologists had remained, as a rule, indifferent to it until Dr. Profanter's initiative. In 1886, Professor Schultze invited Brandt to give a public test of his method at the University Clinic at Jena, and we know of Brandt's brilliant victory. Since that time, physicians from all parts of the world have flocked to Stockholm to learn the method from its master.

The full scientific explanation of Brandt's successful cures first appeared in 1888 through the researches of Professor v. Preuschen<sup>1</sup> upon the pelvic muscles, and the influence exerted by contractions of the levator ani upon the axial position of the uterus and upon the vaginal canal.

I will not go into the details of Brandt's method, as it is not long since I have presented it in a paper read before the Massachusetts Medical Society, but will simply remind you that this method does not confine itself to bimanual massage and so-called "liftings of the uterus," with subsequent powerful adductive movements of the lower limbs, nerve pressure, etc., but first and last in every *séance* are given regular gymnastic movements that lead the blood to or from the abdominal organs, and which are determined by careful calculation for each case. I will quote from the above mentioned paper, what I said about the technique and action of the valuable *uterus liftings*, as this is the more difficult to perform and understand. A practical assistant is required and the treatment is only used, as a rule, when the uterus lies forward or, at least, is so placed for the time being. The patient assumes a half-lying position on a gymnastic bench. The physician sits at the left side, passes the left hand under the patient's knee

and enters the vagina; places the womb in the normal position, if necessary, and while keeping the left forefinger on the cervix presses it gently backward and upward with this finger; at the same time he lays the outside hand on the middle of the abdomen, in a direction from above downward, pushes the skin gently downward so it does not become rigid but can be pushed upward again when the womb is lifted; the hand rests on the forward, upper surface of the womb, thus showing where it is to be found. The assistant has in the meantime so placed himself that he can with his hands held together in a half supine position, parallel to the abdominal wall, press into the pelvis on the anterior side of the womb with the finger tips down to the os internum; there, if possible, he should meet the physician's forefinger. Without losing his hold around the uterus, the assistant lifts it up, giving delicate, light, vibratory motions to the hands, so that he seems to try to lift the cer-

Brandt's position of the "inner hand." The forefinger in vagina (sometimes in the rectum), and the unused fingers of the hand perfectly straight and firmly together, resting closely against the body, and taking, together with the palm, the shape nearly of the inner gluteal region; the thumb is held a little forward of the os symphysis. When necessary, Brandt has confined the thumb in vagina and the forefinger in the rectum.

vix or orificium externum lengthwise of the os sacrum's curvature from below, in the median line, upward, so that the fundus uteri follows, though not to the same extent. When at the beginning of the movement the uterus is in a more or less upright ante-position, it can be placed finally in a more horizontal one, with cervix in prolapsus-uteri, even as high as the promontorium, the fundus leaning forward. The uterus is thus lifted more or less high, is held in this position a few seconds, or even a moment, and lowered by the assistant more or less rapidly, according to the desired effect. The movement is repeated in this way three times at each *séance*. The physician always assures himself that the womb lies in proper position forward at the close of the movement. If this should not be the case the uterus is correctly placed before and after each new lifting. If the uterus liftings are not properly done they can hurt the patient very much. After the liftings some strong movements are always given as before stated for the adductores femorum, during which the levator ani contracts, as has been proven by experience.

<sup>1</sup>Die Heilung des Vorfalles der Gebärmutter durch Gymnastik der Beckenmuskulatur und Methodische Uterushebung. Centralbl. f. Gynäk., 1888.

Since Ziegenspeck, and after him v. Preuschen, have drawn attention to what was unsuspected before, the significance of the levator ani in holding the uterus within the pelvis or, in other words, in preventing prolapsus, it may be allowable to enter more specially on its anatomy. The muscle levator ani punctum fixum is, as we know, the forward half of the little pelvis as far as the spinæ ischii; its punctum mobile os coccygis. In the female body the anterior fibers of the levator ani extend down the sides of the vagina; through this muscular base or levator ani the three pelvic canals must push their way down. A contraction of the levator ani has, therefore, says Ziegenspeck, as consequences:

1. A crowding together of these canals from back to front.
2. A change of position of the canals from this point forward and upward toward symphysis.
3. A disturbance through the distance from the spinal line, as well for the portio vaginalis as for the vaginal opening into the diaphragma pelvis which otherwise lies in this line.

A scheme of the "uterus liftings," showing the uterus' axis in different phases during the movement.

In contraction, then, of the levator ani, the vagina becomes really bent with the angle backward, so that part of the vagina which is over the diaphragma pelvis takes a nearly horizontal position when the patient is standing. Both the increase of distance from the spinal line and the changed position of the vagina secure the portio's position in the pelvis.

Professor v. Preuschen continues: The levator ani has a double function; it decreases the width of the vagina and, by causing a horizontal bending, places the upper portion of the vagina in a condition to bear up the portio; it interposes a barrier for the down-sinking portio. Whether this barrier can really hinder the descensus of the portio depends, on the other hand, on its relation to the position of the uterus. If the uterus is retroverted, the weight of the bowels drives the portio forward in the direction which comes finally to that point where the horizontal direction of the vagina merges into a downward slant. The first strong pressure from the bowels can then cause prolapsus. It is quite different if the uterus is anteverted and meets the horizontal portio at an acute

angle opening forward. As long as this position exists, or as long as the uterus returns to it, and after every change of position, pressure of the bowels brings the portio only more firmly against the barrier formed by levator ani and prevents prolapsus. Now as the uterus in nearly every case of prolapsus takes a retroverted position, the secondary aim of the treatment is to overcome the retroversion and convert it into an anteversion. This indication is filled by the methodical uterus liftings after Brandt's method.

Furthermore: Schultze has shown that the causes of retroversion can for the most part be traced to abnormal fixations depending on inflammatory processes in the cellular tissues of the pelvis, and Freund and Ziegenspeck have shown that it consists mostly of a mass of tissue and muscular fiber, the scarred retractions of the tissues between the bladder and the uterus. Any attempt to bring the uterus into anteversion therefore, tends to stretch the abnormal fixations between the uterus and bladder, as the portio again takes its normal position with relation to the spinal line. This is in the most perfect manner, induced by the "uterus liftings" of Thure Brandt.

The gynecologic kinesitherapy has its fixed indications and contra-indications. The indications are: Chronic or subacute inflammation in the cellular tissues of the pelvis and their secondary changes; exudation, para- and perimetritis and subsequent misplacements (retroflexions, anteversions and ante-flexions; diminished mobility of the uterus; misplacements of the ovaries with twisting of the vessels and nerves, adhesions, etc.); oöphoritis and para-oöphoritis; chronic metritis (sometimes endometritis), cervical catarrh, descensus and prolapsus uteri, vagino-cysto-rectocele, swelling of the tubes, hema-tocele, pericystitis and proctitis with secondary weakness in the sphincter vesicæ and ani.

As contra-indications are stated: Malignant tumors, acute pelvic peritonitis, newly established inflammations in general, salpingitis, gonorrheal, purulent, tubercular and septic processes in the uterus and its adnexions, tubal pregnancy and finally excessive fat in the abdominal wall.

A regular pregnancy is not always to be considered as a contra-indication and Brandt himself, with his marvelous experience, has many times prevented miscarriages by lifting movements, immediately relieving labor pains and hemorrhage; usually after the first or second day he follows the treatment by gentle massage or short tangential strokes from fundus downward to the isthmus.

In spite of the fact that gynecologic kinesitherapy is a laborious method, fatiguing to the physician and patient, requiring daily seances for weeks or even months, it is practiced more and more by European physicians and clinical gynecologists besides, whose time, mind, and strength surely would not be sufficient to devote to unnecessary and fatiguing manipulations. The fact that such men as Schultze, Profanter, Schauta, Dührssen, v. Preuschen, Jentzer, Stapher and others, introduce kinesitherapy into their great operative gynecologic practice, shows best what worth they place on Thure Brandt's method.

It would be too much to enumerate here all the cases of successful cures which have been published in the gynecologic journals of the world up to date, or to compute statistics; I will only state that the latest presentation of the subject was made at the

at the International Medical Congress at Rome by Professor Jentzer, of Geneva, when among others he submitted a brief statistical account of 145 cases treated by himself personally, namely:

1. Two cases of prolapsus with lengthening of *colum uteri*. Age, 23 and 29 years. Treatment and cure from twenty-three to thirty-five days. No relapse. In the second case the uterus fell again into retroflexion.

2. Fifty-seven cases of partial involution after confinement or miscarriage, without retention of placenta. All cured after twelve days to two months.

3. Twenty-two cases of parametritis, one of which was the width of two fingers below the navel. All healed after two to six months treatment.

4. Nineteen retroversions. Cure in two cases only. As he saw Brandt had very fine results in this class of cases he explained his lack of success by his inexperience in Brandt's technique. He adds that in fifteen of the cases, retroversion was complicated with adhesions and the massage caused by lessening the latter a considerable subjective improvement, in spite of the continued unfavorable position.

5. Eleven cases of weakness in the neck of the bladder after several confinements. Cure in eight cases. Treatment one to four weeks. One case improved. Two cases unchanged.

6. Seven cases of hydrosalpinx. Cure in four cases. The other three unchanged. Two of the latter have been cured by Dr. Vuillet by vaginal puncture.

7. Menorrhagia in twenty-seven cases, nearly all in connection with the climacteric period, in eight cases of which "curettage" was resorted to, but without result. Cure in twenty-three cases after one to three months; two cases improved; two unchanged.

The above statistics are almost a perfect type of all those given by different physicians of their experience with Thure Brandt's method, and my own experience corresponds to this entirely. As for certain retroversions which *quod situm* show results with little encouragement, but, *quod salutem subjectivam* are very satisfactory, they depend, as already above named, most frequently on the drawing together of a scar after inflammation in the tissues between the bladder and uterus, but also not infrequently on a relaxation, a lengthening of the ligamenta Douglassi. To treat these changes of position with pessaries or operations, with medium fixation in the opposite direction, fills, it seems to me, *indicatio causalis* just about as often as a man could fix the "head erect" in torticollis with bandages or "an operation on the other side;" moreover it should be remembered that as Ziegenspeck demonstrated, even the decreased mobility of the uterus is a form of displacement.

It may look very well to be sure, in such a case as retroversion, to make an incision of an inch in length in the abdominal wall, draw up the ligamenta rotunda with sutures and in this way fix the fundus uteri forward; but the fundus does not constitute the whole uterus and it is not certain that the cervix, isthmus and the lower portion of the uterus lie any more normally after such an operation because the fundus does—so much more uncertain, since we know that the ligamenta rotunda signifies little to the uterus in maintaining its position; so little in fact, that they can be loose and sinuous

as the intestines after, for example, repeated confinements and still the uterus will lie anteverted. Turn the fundus as much as you will and let the cicatrice drawing between the bladder and the uterus remain, then the mobility of the organ will be abnormally diminished and will remain.

Statistics show, it is true, that pain ceases after such an operation but how long? Here they most frequently maintain silence. It is comparatively seldom that displacement itself needs to be attacked, just as in case of chills it is not the shivering one must deal with, but as a rule it is the cause to the secondary displacement which must first be treated. A proof of this lies in the fact that many displacements exist without causing the least inconvenience to the patient, and why? Because the cause of the abnormal position of the uterus is too slight to occasion pain, but sufficient to cause displacement. This is why many retroversions do not cease through treatment a la Brandt, because the ligamenta Douglassi, which are important in the normal position of the uterus forward, have become so lengthened and relaxed that they can not be made to resume their elasticity and normal length, but pains and many other symptoms disappear, nevertheless, because the kinesitherapy could take away the *causa morbi*, i. e., infiltrations or cicatrice contractions. On the other hand, it must be confessed, there are displacements which are the direct cause of pain, etc., which cease almost simultaneously on the correction of false position. I recall, for example, a patient in the third month of pregnancy who was relieved of many inconveniences by a replacement of the uterus which was leaning backward, pressing against the promontorium; also another case, a severe dysmenorrhea which suddenly appeared after two and one-half days painless catamenia, and two hours after eating fried pork and cabbage, which caused great indigestion, cramps and pains with augmented abdominal pressure and which tipped over the neutrally lying uterus; this was changed by replacement, i. e., after a return of free circulation.

The causes of displacement are manifold, and their treatment at present, unfortunately, not less varied. If for one reason or other we can not treat them pathogenetically then it must be symptomatically. Then we must have recourse to pessaries or in preference, operative methods; but this must not be the case in and out of season, but with great discrimination, and not as a rule but as an exception. In a gynecologic practice covering nearly fifteen years, I have seldom used pessaries and then when I did not possess full confidence in Thure Brandt's method; since then the pessary has been laid entirely aside.

To exemplify the value of kinesitherapy still further, the following case of dysmenorrhea yet under treatment may be cited:

Mrs. S. A., 27 years old, married three years, without children, was seized with abdominal pains five years ago, followed by severe catamenia, which so increased from time to time, that during the past year or two she has been compelled to lie in bed five days each month, because of "almost unbearable suffering." On examination two weeks after the last menstrual period, which was as usual, excessively painful, the uterus was found somewhat enlarged, hard and tender, with decreased mobility backward, also in a half retroverted position, the left ovary also somewhat enlarged and slightly tender to the touch. No symptoms from the bladder. The patient had, it may be added, been attended two years by a good gynecologist without result. She was now treated with uterine massage and "uterus liftings," also

strong movements leading the blood from the abdomen. Fourteen days after the beginning of the treatment the menses came, perfectly painless, so that the patient only discovered her condition by accident, "scarcely believing her eyes." The treatment has been continued without interruption and will go on until the uterus becomes as free and mobile as desirable.

Next to a sharp instrument there is surely no gynecologic method so effective, so universally available and yet so reliable as kinesietherapy. When one has become master of the method he can not do harm by its use and all who have tested the methods, choosing their cases with discrimination, agree in their opinion that gynecologic kinesietherapy is of the same benefit as massage and medical gymnastics in their place. Yet it is true that all these diseases are not cured by kinesietherapy. In gynecologic practice it has its own great special field, just as the knife, which it should never over-reach. It may be added that kinesietherapy may be used very often with our other gynecologic methods.

If gynecologic kinesietherapy is used only according to its indications and then only when a thorough knowledge of the method shows it to be the surest and swiftest means to the desired end and when it is applied by physicians only, as a rule, who are gynecologists, then it is certain that even the most prejudiced physicians would be convinced of its advantages. One and all who have, after making themselves competent, tested it, gladly coincide with this opinion.

Professor Jentzer's closing words to the above mentioned paper were: "We call upon our colleagues to exert their influence to have this new therapeutic method introduced into the course of instruction at universities;" though I think at present one must "make haste slowly," and be better content with the admonition to gynecologic specialists not to delay acquainting themselves with a method which has been tested in at least 10,000 cases in different countries, and has never yet been known to injure, but instead, it has only improved and most frequently healed the sick.

## EXPERIENCE OF AN AMERICAN PHYSICIAN IN MEXICO.

BY D. H. GALLOWAY, M.D.  
CHICAGO.

In March, 1893, I received the appointment of assistant surgeon in the service of the Mexican Central Railroad. This road extends from El Paso, Texas, to the City of Mexico, a distance of about twelve hundred miles. The main line and branches make about two thousand miles of road operated by this company. Every employe contributes a certain portion of his wages to the support of the medical department. This consists of a chief surgeon, with headquarters at Aguascalientes, and ten assistant surgeons. There are four hospitals—at Chihuahua, Aguascalientes, the City of Mexico and Tampico. An assistant surgeon is assigned to each, and the others are stationed at intervals along the road. Cases that can be moved and that require hospital treatment are sent to the hospital most convenient to the scene of accident. Should patients desire it, they may be treated in their own homes, but in that case the department furnishes only medical and surgical care and medicine. In case of contagious diseases the company furnishes a house, nurse and everything needful.

I went to Aguascalientes, a city of 40,000 inhabitants, about three hundred and fifty miles north of the city of Mexico and twenty-five hundred miles from Chicago. I remained in the hospital there about six weeks and was then ordered to Silao, a city of 20,000 inhabitants, 126 miles farther south.

The difference between Mexico and the United States is, in many ways, very striking, but in nothing more so than in medical, and particularly in surgical, matters. I occasionally met the Mexican doctors in consultation and at operations, and very few made any pretense of keeping an appointment on time. I met—or tried to meet—one doctor by appointment eight or ten times, and on no occasion did he arrive within an hour of the time appointed. On one occasion I completed a small operation, cleaned my instruments and was leaving the house when he arrived. The Mexican, under such circumstances, never expresses surprise or disappointment. He did not appear to think that any apology or explanation was due me for his tardiness or due him for my having proceeded without him. Mexico certainly deserves the name of the Land of "Poco Tiempo" (in a little time—after awhile).

Chloroform is used almost exclusively, and I never heard of a death from its use. They administer it from a little cone which is made of a piece of stiff paper and filled with cotton. This cone is such as the grocer extemporizes in which to dispense a few cents worth of spice, and is three or four inches long and an inch to an inch and a half across the large end. In this way they will use an ounce to an ounce and a half in getting the patient asleep, but the process is so wasteful that the patient gets but little.

In 1839 a law was passed requiring all applicants for the privilege of practicing medicine and surgery, to pass an examination in medicine conducted in the French and Spanish languages. This does not apply to graduates of Mexican medical schools. This law is still enforced in some of the States of the Republic. There are few medical works in Spanish, and, in fact, not many scientific books of any kind in that language. Therefore the schools use books in French. All well educated Mexicans speak French, and just now there is a strong movement toward the study of English. The Spanish language is also deficient in business terms and so it is necessary to draw on the vocabulary of other languages. English is the great source of supply for this purpose. These words must be made to conform to Spanish rules of spelling and pronunciation, and where any change is made in the former it is always an improvement as that must be "fonetic."

But to return to the matter of registration: There is a possibility of becoming registered in some States without the ordeal of an examination. To accomplish this, it is necessary to proceed as follows: A letter must first be obtained from the President of the college issuing the diploma, stating that the applicant is the lawful owner of the diploma presented. This letter, with the diploma, is to be sent to the Secretary of the State Board of Health. He will make a certificate which will state that the college is a regularly chartered medical institution recognized by the State Board of Health, and that certificates are issued to its graduates on the diploma. This certificate is attached to the diploma and it all goes to the Secretary of State of the commonwealth. That individual certifies that the signature to the

previous document is that of the Secretary of the State Board of Health, and that his official statements are entitled to full faith and credit. This is attached to the others and goes to the Governor. He certifies that the accompanying document is signed by the Secretary of State of the commonwealth and that full faith and credit are due his official attestations. The Governor's certificate is added to the collection and it is then taken to the Secretary of State of the United States. This officer certifies that the document hereunto attached is under the seal of the State of —, and is entitled to full faith and credit. You will notice that each man vouches for the *official* statements of the other, and leaves us in doubt as to whether his private statements are entitled to the same faith and credit.

The package of documents is forwarded to the Mexican Legation, and the Envoy Extraordinary and Minister Plenipotentiary of the United States of Mexico in Washington, certifies that the foregoing signature is that of the Secretary of State of the United States, and the seal that of the department of which he is in charge. Each document bears a gold seal, except that of the Secretary of State of the United States, which is provided with a red seal and blue ribbon. Thus reinforced, the diploma is ready to go to Mexico. Thus far there have been no charges except those of the express company which transports it from place to place. In the City of Mexico it is presented—together with \$10.10 in document stamps—to the Secretario de Relaciones Internas. He certifies that the foregoing signature is that of the Mexican Minister in Washington. The next move is to the Governor of the State in which the applicant expects to practice. He will add—or perhaps he will not—his signature to the illustrious list. The next and last call is on the mayor of the city or town, and possibly this call will have to be repeated once a month and a license fee of \$1 or \$2 paid.

The fortunate—or unfortunate—individual who has thus prepared himself to practice medicine and surgery is now ready for a call. Should two of his *clienteles* get into a fight and one of them have his femoral artery cut, the doctor may be called in, in which case he will—if he is law abiding—wait for the arrival of the mayor or his representative. If that officer arrives in time—and it is not likely that he will—the doctor will receive permission to tie the artery. If the patient is dead, that will not be necessary and the doctor will not have soiled his hands or his instruments. There is in Mexico a law which forbids any one—even a surgeon—interfering with an injured person until the arrival of some representative of the civil authorities. There is, however, a special clause in the charter of the railroad company which makes it lawful for the company surgeon to attend to employees of the road without waiting for such formality. Hence the first inquiry the doctor makes, when called to a case, is: "Is this man's name on the pay roll of the company?" If the answer is in the negative, he returns to his office or treats the patient on his own responsibility and at his own peril. This law dates back so far that its origin is lost in the mist of many decades. It is acknowledged by all to be a bad law, but, as the mayor said: "We are here to enforce not to criticise the law." I will say, however, that while I ignored this provision of the law, I was assured by both the Governor and Mayor of immunity from molestation. They stipulated that I should not

move the patient from the position in which he had been found.

The cost of a funeral is not great. If the body is that of an American tramp or an unknown or unclaimed native, the cost of burial will be \$5.75. A coffin will cost \$2.50, a permit to inter in second yard, second class, will be \$1.25, four *cargadores*, for carrying the body to the cemetery, \$2. A more pretentious burial costs about \$31. Coffin \$16, a permit first yard, first class, \$5, and \$8 for a monument on which is inscribed name, age and place of birth. This secures undisturbed possession of the ground for three, five or seven years. At the end of that time the grave-digger will exhume what is left of the skeleton, the larger bones will be gathered together and thrown into a vault prepared for that purpose. The smaller bones will go with the sand and clay to help cover up the next occupant of that spot. In Guanajuato there is a vault which contains the remains of more than one hundred and twenty thousand human beings. The bones are thrown in here through a kind of a chute and then piled up without regard to any order. The pile of bones is 250 feet long, 6½ feet wide and 12 feet high. The entire vault is 450 feet long. Three sides of the cemetery are lined with tiers of vaults, each large enough for one coffin. At the end of five years these are emptied. Sometimes the body is found to be mummified. In this condition the remains of an adult weigh but about ten pounds. A number of these mummies are standing along the wall in the unoccupied portion of the vault. It is said that persons sometimes recognize the remains of friends in this ghastly gathering. By paying \$100, a grave or vault may be secured in perpetuity, but this is not usually done. The scenes in this "Panteon" ought to make a cremationist of every visitor.

Silao is situated at an altitude of nearly six thousand feet and has a magnificent climate. In the shade, the temperature ranges from 70 to 80 degrees F., and at night from 60 to 70 degrees. The rainy season lasts from May to September. During that time it rains nearly every day. The shower usually lasts an hour or less and it immediately clears off. In eighteen months there were but three "cloudy" days. Silao probably has the finest climate in Mexico, though that of Guadalajara is very similar. Drinking water is kept in porous earthenware jars and a good jar will keep the contents about 20 degrees below the temperature of the surrounding atmosphere. I placed a thermometer on the ground in the sun and it registered 127 degrees F.; moving it four inches, into the shade of a building the mercury went down to 81 degrees F., and in a jar of water it dropped to 61 degrees F. This water is more palatable than ice water.

For several years typhus fever has raged all over the table land of Mexico but has now about disappeared. Smallpox is endemic in almost all large towns and cities. The people think but little of it, and it is quite common to see children on the street in all stages of the disease. Malaria is common but ordinarily yields readily to quinine. There are some cases of the pernicious variety. Next to typhus, pneumonia is the most dreaded of diseases. A very large percentage of cases are fatal and that within forty-eight hours.

Doctors are almost never called to attend in childbirth. Midwives look after this, and blindness from

gonorrheal ophthalmia, is common. The poorer classes are indescribably filthy and consequently skin diseases abound. Many of them never bathe. The shoes of these poor people consist of a piece of sole leather fastened to the foot by means of straps. Their heels crack and these cracks sometimes become infested with bedbugs.

Urticaria is common among the Americans here, but they can not be charged with personal uncleanness. Nasal catarrh is all but universal among the Americans. Pulmonary tuberculosis is not common, and I believe this would be an excellent climate for consumptives if sent here before the disease had made too great progress. Chronic bronchitis is unknown and cases arriving are relieved immediately and soon permanently cured.

Venereal diseases are fearfully prevalent. A Chicago firm is doing a rushing business "curing" syphilis in three days at \$150 per cure. They give twenty-five pills which are guaranteed to contain no mercury. The pills are a drastic cathartic and cause emesis and salivation, the latter so copious that the patient lies with his head on the edge of the bed and allows the saliva to run from his mouth into a vessel. The company claim that every "sore" about the genitals is syphilitic, so their marvelous "cures" are readily accounted for. There have been several cases of insanity reported as a result of this treatment.

A great many people have cancer and other tumors, as might be expected when they are so afraid of the surgeon's knife. The Mexicans have a sure cure for cancer. I have never seen it tried. A live toad is cut open and bound upon the tumor. "In three or four days the cancer comes out, roots and all." For brain fever they similarly cut open a pigeon and apply it to the cranium. There are a few cases of leprosy, to which the authorities pay no attention whatever.

The most common injuries to railroad men are the crushing of fingers and hands between the bumpers of freight cars. These wounds almost always suppurate. Injuries to the hands of machinists almost never suppurate. Their hands are covered with grease and oil from the machinery, and if, when injured, they are bound up without washing they will usually heal by first intention.

If there is to be a surgical operation at the home of a Mexican, all the friends and neighbors flock in to see it. That is, as many of them as the size of the room will admit. They consider the operation as a legitimate entertainment. This is sometimes inconvenient on account of the crowding, and at other times rather disagreeable, because they feel it their duty to interfere when they think the performance has gone far enough. It may be necessary to leave the doors open to the street, if this is the only source of light, as is often the case. These people may not be able to read or write or count to ten, yet they assume to dictate when and where and how much a surgeon shall cut. But why not? The Illinois Humane Society insists on being allowed to assume supervision over operations on animals, conducted by educated surgeons, and all the members of this society can, presumably, read and write and count above ten. Surely the former case is not more absurd than the latter. On one occasion three of us were actually attacked by members of a mob and had to defend ourselves with one hand, so to speak, and operate with the other.

There are many hot springs in Mexico. There is one about four miles from Silao, the water of which contains much sulphuretted hydrogen and has a temperature of 120 degrees F. There are bathrooms maintained here and many people go out from Silao to bathe. The bather will remain—I could not—in the water for five or ten minutes, then come out, wrap in a sheet and lie down. In a few minutes profuse sweating begins which lasts ten or fifteen minutes. At Amanjilla are a number of boiling springs. Owing to the altitude, the water boils at 198.5 degrees F. This water seems to be very pure, apparently containing almost nothing in solution. There is a group of hot springs at Aguascalientes, the temperature in the different ones ranging from 84 to 104 degrees F. These, and some still more famous at Santa Rosalie, are believed by the people to have great medicinal properties. There are still others near the City of Mexico. Some of these places will no doubt become famous resorts in the future.

In a country where one may in an hour pass from the temperate climate of a high altitude to a tropical climate at the sea level, some curious effects are noticed. As one goes down the mountains toward the coast, nasal and pharyngeal catarrh immediately disappears. It comes back slowly on returning to the tableland after a few weeks' stay at sea level.

Pneumonia on the coast is not feared and I could not find that it is ever fatal there. Yellow fever remains the year round at Vera Cruz, but is much worse in summer than in winter. The disease does not invade the mountains, but the people believe that it is fatal to remove a patient suffering with the disease to the elevated table land. The lowland fevers are much dreaded by all who live at a high altitude. I am inclined to think that these fevers could be largely, if not entirely, prevented by sterilization of food and water. I think the name, bad air, (malaria), should be changed to bad water. There are comparatively few springs and the drinking water comes from shallow wells, rivers, or even stagnant pools.

Mexico is essentially a volcanic country and there are a great many places affording grand and beautiful scenery. Probably no railroad on this continent affords more magnificent scenery than that to be seen on the Tampico branch of the Mexican Central. No one making a trip to Mexico should fail to see this wonderful panorama. Nature has here thrown up gigantic mountains and then as if ashamed of her roughness has clothed them to their very top with an impenetrable forest of trees and shrubs and vines. Millions of brilliant tropical flowers of a thousand different varieties, enchant the beholder. Any rock too rugged or bare to support a tree or shrub is covered with a smooth mantle of vines. In many places white flowering vines covered the rocks and trees in such abundance as to look, in the gathering twilight, like drifted snow. On one side of the train you may look down almost perpendicularly 1,500 feet to the river, the water of which is as blue as indigo. On the other side, the same distance up to the forest clad mountain tops. Here you may see at a glance coffee, vanilla, bananas, mahogany, rubber, orange, lemon, sugar cane, and an infinite variety of other trees and vines, making a jungle so dense that a man could scarcely penetrate ten feet from the road. If the fevers of this country can be prevented or overcome, one need look no further for paradise. Here the beggar—the most prominent feature of the high

country landscape—disappears and the thief has gone to keep him company. Here the maximum return is to be had for the minimum of labor. Here nature is kind. Here all creatures—except the plasmodium malarie and the mosquito, appear to dwell together in harmony.

## THE IMPORTANCE OF URINALYSIS IN DIAGNOSIS.

BY A. B. WALKER, M.D.

CONSULTING PHYSICIAN TO THE AULTMAN HOSPITAL.  
CANTON, OHIO.

Elimination of the worn-out products of tissue change and the unappropriated parts of the food takes place from the body in the expired air, skin, feces and urine. The oxidized carbon of the tissues by the lungs and cutaneous surface, the insoluble *débris* of the food excreted by the intestines, while the urine contains essentially the nitrogenous and other soluble products.

The urine containing the watery constituents of the blood, with some dissolved salts, is one of the most important excretions from the body, and with our present knowledge of urinalysis much can be learned by its examination. The changes which this secretion undergoes in health and disease have been studied since the earliest history of medicine. Hippocrates taught the effects of food and drink upon this excretion, its variation in color, odor and transparency, attributing their changes to disease of the urinary organs. Galen simply added to this knowledge the variations of urine in health.

It was not until after the middle of the seventeenth century that any attention was paid to the chemic analysis of this important excretion; prior to that time attention was only given to its physical characteristics, as its appearance, etc.

Cartungo in 1770 was the first to find albumen; Cruikshanks in 1798 pointed out the connection between its presence in urine and dropsy; still the relation of albuminuria to kidney disease was not appreciated until it was proved by Bright in 1827.

Willis discovered sugar, and Rouelle in 1773 urea. To Steele and Wallaston is due the earliest knowledge of the composition of urinary calculi.

Since these important discoveries very many others have been made, as well as the improved modes for examinations. They have also been so simplified that at present every physician and surgeon can have the apparatus and chemicals in his office and make the necessary chemic examination. But when the urine is pathologic, that is, containing albumen, sugar, uric acid and phosphates in excess, or there is found evidence of pus or blood, a careful microscopic examination should be made by one of experience to ascertain the condition of the urinary organs, and, if possible, to determine the origin of the pathologic product.

If physicians and surgeons would avail themselves of this important aid to diagnosis, much more good could be accomplished to their patients, many a life spared and thousands of dollars saved life insurance companies.

As urinalysis requires but a few moments of time, and the results from it are so positive and true, we feel that no opinion of a case of any importance should be given without there having been made a careful examination of the urine.

Many a case of Bright's disease might be prevented, if, when the first symptoms of the disease manifest themselves, a careful examination of the urine be made and the proper treatment and diet prescribed.

Three years ago a young man at the age of 25 years consulted me, when, upon examination, I found evidence of incipient Bright's disease. There was a small amount of albumen in his urine, with some tube casts and epithelium present. His diet had consisted largely of nitrogenous food, as beefsteak and eggs. A change in his diet to a more liberal use of vegetables and fruits, as well as the cereals, with some medicine to regulate his bowels and thereby relieve his over-worked kidneys, has wonderfully improved his condition, and at last examination, about six weeks ago, his urine was free from excess of albumen or any evidence of disease of kidneys.

Many more cases of the kind might be given, as where there is sugar, uric acid or phosphates in excess in the urine, when, if detected early and their cause as far as possible removed, much good could be accomplished, lives prolonged, and cures very often performed.

When pus is suspected to be present in the urine, the specimen should be examined with the microscope, to ascertain which part of the urinary tract it is from, and, with our present knowledge, this can be done, when the proper treatment can be given. We should not make the mistake a noted physician in one of our large cities did quite recently, that of removing a normal kidney from a man who had suffered with pain in his loin, had frequent chills and passed pus with his urine. A *post-mortem* in this case a few days later revealed the fact that he had had a chronic cystitis. Had the urine in this man's case been properly examined, the diagnosis could have been made *ante* instead of *post-mortem*, this man's life spared to his family and the surgeon's reputation in that community preserved.

When the urine is thought to contain blood, the microscope alone will aid us as to its origin. We have a damage case now in our courts of a man who was injured in a railroad wreck, who at times passes urine that looks as though it contained blood. I had it examined by a microscopist, and he claimed it did not contain blood, as there were no blood corpuscles to be found. I sent him another specimen, with the word that he was certainly mistaken, for nothing else would give it such an appearance but blood. As this case had symptoms of having a floating kidney from traumatism, I was very anxious to know where this blood came from and to trace it to his kidney if possible. His second report revealed no blood corpuscles in the specimen of urine, but that the specimen contained hematine in large quantities, which leaves us to infer, with a considerable degree of certainty, that the blood in this case came from his kidney. The action of the urine on the blood evidently destroyed the corpuscles, leaving the hematine in solution, when if it had been from the bladder or urethra, the blood corpuscles would have been present.

In every case where ether is to be given as an anesthetic, a careful examination of the urine should first be made to determine the condition of the kidneys, when if they show the least symptom of disease, it should not be given, for it is known to exert an unfavorable influence upon them. Many cases of transitory albuminuria are noticed after

ether has been administered, proving that it does affect the kidneys. Then when the kidneys are in an advanced stage of disease, the ether is likely to cause a congestion of the organs and thereby prevent the elimination of urine, when death will surely be the result.

The following case made a lasting impression on my mind—that of a young lady, who had a large ovarian cyst, that I was called by another physician to remove last April, and as there were no symptoms whatever of disease of her kidneys a urinalysis was not made. The operation was quickly done, requiring but a few moments. She took the ether as an anesthetic nicely and came out of its influence in a very short time. Four hours later, about two ounces of urine was drawn from her bladder, which was the last and only urine secreted by her. A *post-mortem* examination two days later revealed both her kidneys in an advanced stage of Bright's disease. The small part of the kidneys that had the appearance of having been physiologic before the operation, was in a highly congested condition. A urinalysis in this case would have undoubtedly shown a large amount of albumen, tube, casts, etc.

I am surprised that all life insurance companies do not require an examination of the urine, even for their small risks. I believe the time is not far distant when they will see the necessity and demand it in all cases. Only last February, one of our local physicians examined and passed a man for one thousand dollars (\$1,000) where a urinalysis was not required, who was in an advanced stage of Bright's disease of the kidneys. At time of examination his urine contained over 30 per cent. of albumen. Six months later this man died from the effects of Bright's disease.

A simple chemic urinalysis would have saved the company this risk, and the physician the embarrassment of having passed such a subject.

45 W. Tuscarawas Street.

# ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 84.)

## CHAPTER III.

*Case 2.*—Yellow fever: high temperature, 106.5 degrees in axilla; suppression of urine; black vomit; recovery; treatment, ice water injections to rectum; application of ice to epigastrium; sulpho-carbolate of sodium internally. Dominick Polmisano; age 18; native of Italy. Has resided in New Orleans six years; residence St Anne Street near levee. Black hair, black eyes, dark complexion. Had a slight chill, followed by pain in the head and back and fever. Oct. 14, 1873. Entered Charity Hospital, October 16, at 4:30 P.M. At this time the patient had high fever; hot skin; face very red with great capillary congestion of the surface generally. Capillaries of conjunctivæ, greatly congested and of a yellowish tinge. Body emits an offensive smell. Breath very offensive. Tongue red at tip and edge and coated with light yellow fur shading into brown in the center and root of the tongue. Gums very red. Patient complains greatly of severe pains in heart, epigastrium, lumbar region and lower extremities. At 8 P.M., pulse 106; respiration 28; temperature of axilla 104 degrees.

R. Potassii bromid . . . . . ʒij  
Liquid ammonia acetates . . . . . fʒiv.  
Mix: Tablespoonful every four hours.

October 17, 8 A.M., pulse 100; respiration 28; temperature of axilla 106.5 degrees. Patient restless; complains of intense pain in the head, back, epigastrium and extremities. Nausea. Great congestion of capillaries of face and extremities. Skin presents the appearance of a purplish and scarlet rash. Conjunctiva injected and jaundiced. Tenderness upon pressure over epigastrium. Tip and edges of tongue red, coated in center; gums red. Has passed no urine since entering the hospital; when the catheter was introduced, only one fluid ounce of urine was drawn off, which upon chemic and microscopic examination was found to be loaded with albumen and bile, and casts of the tubuli uriniferi and excretory cells of the kidneys. To control the nausea, an ice bag was placed over the epigastrium. For the suppression of the urine, ice cold water was thrown up the rectum in large quantities. The injections of ice water had the desired effect, and caused the excretion and evacuation of a considerable amount of urine, which was heavily loaded with albumen and granular casts. In order to prevent septic changes in the black vomit if it should be formed, I ordered the following:

R. Sodii, sulpho carbolate . . . . . ʒi

Divide into three parts, one part (20 grains) dissolved in water, every three hours. Brandy and carbonic acid water. Ice and milk, internally in small quantities at regular intervals. Small fragments of ice to be held in the mouth.

At 8 P.M., condition unchanged; jaundice and nausea and restlessness increasing; urinary excretion very scarce. Urine contains albumen, bile and granular casts and cells of tubuli uriniferi. Pulse 98; respiration 26; temperature of axilla 104.1 degrees. Continued ice bag to epigastrium; ice water enema; sodium sulpho-carbolate; iced milk and brandy diluted with carbonic acid water.

October 18, 4 A.M., the patient has begun to throw up black vomit. Continued to eject black vomit at short intervals quite freely until 8:30 A.M. The sulpho-carbolate of sodium appears to have exerted some beneficial effect, as the black vomit is of a brighter color than usual and contains coagula of blood.<sup>50</sup> At 8 A.M., pulse 82; respiration 28; temperature of axilla 102.1 degrees. The supervention of black vomit has been attended by a reduction of the temperature. Great congestion of peripheral capillaries. Jaundice; gums red; tip and edges of tongue very red, center and body of tongue coated with yellow and brownish-yellow fur. Blood oozed from tongue and gums. A small quantity, about half a fluid ounce, of urine drawn off by catheter. Urine loaded with albumen, casts and excretory cells; also contains bile. Patient delirious and very restless. A strong man was ordered to sit by his bed, to keep him as quiet as possible and carefully covered, and to prevent him from rising and getting out of bed.

R. Sodii sulpho-carbolate . . . . . ʒij.

Divide into six powders; one powder every three hours. Inject one pint of ice-cold water into the rectum, at intervals of four hours, until the kidneys act freely. Apply ice-bag to epigastrium. Apply sinapisms to back of neck and lumbar region over seat of kidneys. Administer at regular intervals of two hours, alternately, small quantities of brandy largely diluted with water charged with carbonic acid, and iced milk. Fragments of ice to be placed in the mouth. The brandy and carbonic acid water appeared to increase the nausea and vomiting, and were accordingly discontinued; the sodium sulpho-carbolate, on the other hand, appeared to quiet the stomach, and during the day the black vomit ceased and the patient enjoyed several hours of refreshing sleep. At 6 P.M., pulse 80; respiration 24; temperature of axilla 102 degrees. Patient in much the same condition but not so restless. The injections into the rectum of the ice-cold water were followed by a pretty free evacuation of high-colored albuminous urine. Black vomit has ceased but nausea still continues. Hemorrhage from the tongue and gums still continues. Continue treatment.

October 19. Condition of patient still alarming; great congestion of capillaries; the face presents a deep mottled purplish appearance; hemorrhage from gums and tongue. No return of black vomit. Kidneys excreting urine more freely. Pulse 94; respiration 24; temperature in axilla 100 degrees. Continue sulpho-carbolate of sodium, 20 grains every three hours; also ice-water injected occasionally if kidneys do not act freely. Iced milk at regular intervals; also small quantities of borax and water charged with car-

<sup>50</sup> These results appeared also to be due to the local application of ice to the epigastrium, and the injection of ice-cold water into the rectum, which not only controlled the nausea, but also reduced the excessive temperature.

bonic acid. At 7 A.M., patient apparently improving; intellect clearer; black vomit has ceased; nausea relieved; capillary congestion less; jaundice not so marked. The ice-water enema caused a free discharge of high-colored albuminous urine. Pulse 76; respiration 20; temperature of axilla 100.5 degrees. Continue sulpho-carbolate of sodium, ice-water enema, iced milk and brandy and carbonic acid water; re-apply ice-bag to epigastrium; nourishment of the patient has up to the present time been confined chiefly to iced milk.

October 20, 8 A.M., patient decidedly better; vomiting has ceased; no nausea; free secretion of urine; capillary congestion disappearing and jaundice less intense; pulse 68; respiration 18; temperature 99.5. From this date the improvement of this patient was steady, and on October 22 the capillary congestion had almost entirely disappeared and the coloration of the skin was far less intense. Patient complains that he does not get enough to eat; says that he feels "bully," and putting his hand on his epigastrium says that his "belly is hungry, and cries all the time for something to eat." Continued to improve and was discharged. The following is the record illustrating the relations of the pulse, respiration and temperature in this case:

Date.	Pulse.		Resp.		Temp.		REMARKS.
1873	M.	E.	M.	E.	M.	E.	
Oct. 16		106		28	104	104	Fever.
" 17	100	98	28	26	106.5	104.1	Jaundice, capillary congestion, albumen and casts in urine.
" 18	82	80	28	24	102.1	102	Urinary suppression, black vomit, hemorrhage from gums.
" 19	94	76	24	20	100	100.5	Black vomit, less urine, scant hemorrhage from gums.
" 20	68	70	18	24	99.5	100.1	Vomiting arrested, urine more abundant.
" 21	66	64	20	22	100	100	Improving, hungry, urine abundant.
" 22	62	60	20	19	99	99.8	Continues to improve.
" 23	62	66	20	24	98.9	99.4	Convalescent, sitting up, cheerful, bright expression of eyes.

The restoration to health was rapid and complete.

Case 3.—Yellow fever; sudden rise of temperature; treatment, sulpho-carbolate of sodium and quinin; recovery. Wm. H. Williams; native of New Orleans; age 26. Entered Charity Hospital, Ward 27, on the night of Nov. 8, 1873. Patient states that he has been at work for some two months near the city on dredge boat, cleaning out a canal. On the previous day had a chill, followed by high fever and delirium, and in this condition was brought to the hospital. The patient was ordered tablespoonful of the liq. ammoniac acetates, every three hours. November 9, patient is more rational and complains of intense pain in the supraorbital region, along the spinal column and in the thighs and knees. Conjunctiva of eyes congested. Considerable capillary congestion of surface with marked jaundice. Gums red, inflamed and bleeding; tongue red at tip and edges, furred and fissured in center and bleeding. Body emits a disagreeable odor. M., pulse 84; respiration 30; temperature 98.5 degrees. Ordered 20 grains of the sulpho-carbolate of sodium, every three hours. Evening, patient in much the same condition but restless. Temperature 100.5 degrees; pulse 96; respiration 27.

November 10, urine scanty and loaded with albumen and casts of tubuli uriniferi. Pulse 80; respiration 30; temperature 101 degrees. Ordered continuance of sulpho-carbolate of sodium; also ice-water injections into the rectum. Evening, pulse 144; respiration 40; temperature of axilla 106 degrees. Urine scanty and loaded with albumen; high fever; vomiting. I was unable to account for this sudden rise in the temperature.

November 11, fever has subsided and the patient appears to be much better. M., pulse 96; respiration 36; temperature 98 degrees. Evening, pulse 93; respiration 30; temperature 98.5 degrees. Ordered 10 grains of quinin every three hours. Continue sulpho-carbolate of sodium, 20 grains every four hours. Milk punch and whisky diluted with carbonic acid water.

November 12, pulse 96; respiration 36; temperature 98 degrees. Evening, pulse 108; respiration 34; temperature 99 degrees.

November 13, M., temperature 101 degrees; pulse 78; respiration 24. Evening, temperature 99.5; pulse 78; respiration 24.

November 14, patient improving. M., temperature 97.5 degrees; pulse 69; respiration 21. Evening, temperature 97 degrees; pulse 63; respiration 20. Continue quinin 5 grains three times daily, also sulpho-carbolate of sodium.

November 15, M., pulse 60; respiration 18; temperature

96.5 degrees. Evening, pulse 60; respiration 20; temperature 97 degrees.

November 16, patient improving rapidly; albumen has disappeared from the urine. Temperature 98 degrees; pulse 60; respiration 22. Continued to improve. Discharged December 12.

Case 4.—Yellow fever; high temperature, 106.5; jaundice; slow pulse; treated with sulpho-carbolate of sodium, 20 grains every four to six hours; sulphate of quinia; ice-water injections and brandy diluted with carbonic acid water and iced milk. Recovered. Tully Brown; stout strong man; large muscles; brown hair; dark eyes. Has been in America five years. Has been working on the Mississippi River during the past year; occupation laborer. Patient states that he was seized with a chill Oct. 25, 1873, at 9 P.M. The chill and fever returned October 26 and 27. Admitted into Charity Hospital, Ward 24, Oct. 29, 1873. The following is the record of the pulse, respiration and temperature:

Date.	Pulse.		Resp.		Temp.		REMARKS.
	M.	E.	M.	E.	M.	E.	
1873							
Oct. 29	88	96	20	28	106.2	106.2	Some pain in head and back; skin hot and pungent; peripheral blood vessels congested; conjunctiva congested; bowels constipated; tongue red at tip and edges, and coated with brown fur in center; R. Quinia sulph. 9i; divide into two parts, one every three hours.
" 30	52	90	20	28	100.5	104.2	The quinin, 20 grains, appears to have reduced temp. and frequency of pulse, but not permanently; patient sweating profusely and general appearance improved; tongue less red and coated. Continued quinin; chill at 10.30 A.M.
" 31	78	92	25	26	106.5	105	Urine scant and loaded with albumen and casts, restless, complains of pain in head and back; jaundice; nausea; slept but little during night; quinin; sulph. carb. of sodium and ice-cold enema to bowels; R. Quinia sulph. 3iiss; pulv. rhel. 9i; divide into three parts; one every three hours.
Nov. 1	74	78	24	28	101.5	102.5	Patient no better; not so restless; urine less abundant; ice-water enema appears to have been beneficial; less nausea; skin yellow; capillary congestion of extremities; albumen and casts in urine; continued sulpho-carb. of sodium; urine suppressed; complains of pain in abdomen; repeated ice-water enema.
" 2	76	76	24	24	101.8	101.8	Restless; pain in head and abdomen; urine albuminous but more abundant; continued sulph. carb. of sodium.
" 3	84	72	24	22	102	102	Dull countenance; slept but little during past three nights; bowels constipated; urine scant; jaundice; capillaries congested; quinia and sulpho-carb. of sodium.
" 4	59	70	18	20	100	98.5	Improving; urine more abundant; ice-cold enema appears to have been beneficial.
" 5	64	56	22	20	99.8	98.8	Slept well during night; in profuse perspiration; albumen diminishing in urine, which is more abundant.
" 6	62	58	18	20	100	98.8	Albumen disappeared from urine; continues to improve; passed about 32 fluid ounces urine in last 12 hours.
" 7	62	58	18	20	100.5	99.5	Countenance more natural; improving.
" 8	60	58	20	20	99.8	99.8	Tongue moist and clearing off; appetite good; rests well; skin moist; steady improvement.
" 9	60	54	25	18	100.2	99.5	Improving.
" 10	62	66	20	18	98.8	100	Convalescent.
" 11	60	62	18	20	99.5	99.8	
" 12	64	60	16	16	99.8	99.5	
" 13	62	76	20	20	100	98.8	
" 14	60	58	17	20	99.8	99.8	Discharged November 15.

Case 5.—Yellow fever; jaundice and slow pulse; urinary suppression relieved by ice-water injections; sulph-carbolate of sodium internally. Adolph Kammer; age 21, native of Sweden, has been in America six years, in St. Louis, from which place he came to New Orleans. Resided at 153 Levee Street, near the French Market. Had been in New Orleans one week, when he was attacked with fever. Entered Charity Hospital, Oct. 1, 1873, Ward 13, on second day of disease. Tongue red at tip and edges, and furred in the center; gums red; conjunctiva congested; skin hot and dry; patient restless and complains of intense pain in the head and back. The following is an outline of this case:

Date.	Pulse.		Resp.		Temp.		REMARKS.
	M.	E.	M.	E.	M.	E.	
1873							
Nov. 2	84	82	32	43	104.5°	105°	Skin hot and dry; slight jaundice; gums congested; tongue dry and swollen; kidneys acting imperfectly. Although temp. in evening reached 106°, pulse was only 82.
" 3	86	96	32	34	102°	102.5°	Passed a small quantity of urine by the catheter; urine loaded with albumen and contained many yellow granular casts; resp. rapid and irregular, and patient appears in great danger; ice-water injections per rectum appeared to do good; caused excretion of some urine; in evening complained of pain in epigastrium, which was relieved by ice bag to epigastm.
" 4	72	70	28	36	101.5°	102°	During night hemorrh. from gums; passed urine quite freely towards morning; urine dark colored and loaded with albumen and bile; on 3d patient was placed on sulpho-carb. of sodium, 20 gra. every 4 or 6 hours; milk punch, brandy and beef tea and fragments of ice in the mouth.
" 5	54	48	26	24	98.5°	101°	During 4th perspired freely and appeared to be improving; became much more quiet; aedative water to the surface appeared to quiet him greatly; on 5th passes urine freely, looks more cheerful and is improving; jaundice well marked but less.
" 6	52	50	26	22	98.3°	98°	Passed a very comfortable night; jaundice disappearing; urine abundant; still contains albumen, but amount is diminishing.
" 7	46	50	22	24	97.5°	98.5°	Sitting up; all pain has disappeared; complains of nothing but a cough, which at times annoys him; appetite good; sleep quiet and refreshing; jaundice disappearing.
" 8	45	54	22	23	97.7°	98°	During coughing spat up some dark blood; as there was no congestion of lungs and no rise of temperature, the blood was supposed to have come from mouth and throat. Albumen disappeared from urine.
" 9	52	50	26	27	97.8°	98°	Is up and walking in ward. Continues to improve.
" 10	48	48	20	19	98°	98.2°	Continues to improve.
" 11	52	52	26	24	98°	98.7°	Jaundice disappearing rapidly, very slight tinge in skin and traces of yellow in eyes.
" 12	54	52	24	24	98°	98.2°	Gains strength rapidly.
" 13	52	46	26	24	98°	98.2°	Discharged from hospital Oct. 17.

**Case 6.**—Yellow fever; jaundice; urinary suppression; delirium; treatment, ice-cold injections; sulph-carbolate of sodium; urinary excretion reëstablished; recovery. John Pflum; age 26; native of St. Louis; laborer. Entered Charity Hospital, Ward 25, Oct. 1, 1873. Had a chill succeeded by high fever and pain in head and back. The following observations were made:

Date.	Pulse.		Resp.		Temp.		REMARKS.
	M.	E.	M.	E.	M.	E.	
1873							
Oct. 20	78	74	28	26	104.5°	104.5°	Pain in head and back; nausea; tongue red at tip and edge; coated in center; conjunctiva congested; gums red and swollen; face flushed; capillaries of face, chest and extremities congested; high fever; intense thirst; passes very little urine and with great effort; iced milk and ice in mouth.
" 21	72	76	24	26	102°	103°	Bowels constipated; passes urine with great difficulty and experiences much pain in micturition. Pain in head, lumbar region and lower extremities, nausea and vomiting; tongue very red at tip and edges and coated in center; gums swollen and very red; mind heavy and confused; urine scant, albuminous. Ice water injections and sulpho-carb. of sodium.
" 22	66	72	22	24	101.1°	103°	Gums red, swollen and congested; tongue softer and not so red; urine contains albumen and casts; shows acid reaction; conjunctiva and surface yellow; nervous, restless. Ice water injections and sulpho-carb. of sodium.
" 23	66	70	23	24	100°	100°	Improving; not so nervous; tongue clearing; urine albuminous, but more abundant. Continue sulpho-carb. of sodium, ordered also sulphate of quinia.

" 24	64	70	24	22	100.1°	101.1°	Continues to improve; urine albuminous with casts but more abundant; has some appetite; patient still very weak; continue quinia and sulpho-carb. of sodium.
" 25	62	62	22	20	99.3°	101°	Improving. Sulpho-carb. of sodium continued; 20 grains every eight hours, as before.
" 26	64	60	23	23	99.1°	99.7°	Improving; continue sulpho-carb. of sodium; tongue clearing off; skin clearing off; hungry.
" 27	60	59	22	18	97°	98.5°	Improving; although the urine is still loaded with albumen and casts; urine much more abundant and returns to normal standard; and sat up during the day.
" 28	60	56	18	20	97.6°	98°	Continues to improve; albumen disappears from urine.
" 29	60	76	18	24	98°	98.6°	Tongue clear and very near normal in appearance; urine abundant; is up and dressed.
" 30	60	62	18	24	98.8°	100.5°	Bowels regular; urine abundant; patient says that he feels well; walks about the ward.
" 31	60	60	18	28	99.1°	100°	Patient expresses himself as feeling well.
Nov. 1	68	68	20	20	99.5°	99.5°	Discharged in good condition November 10.

It is of interest to note that on October 22 the injections of ice-cold water were ordered and repeated three times. After the third injection, the patient passed quite a considerable amount of urine and fell into a refreshing sleep. The sulpho-carbolate of sodium, 10 grains every two hours, appeared to relieve the nausea. The patient slept well during the night and was able to drink a cup of milk and another of beef tea.

(To be continued.)

## THE AUTOMATIC TISSUE FORCEPS.

BY EMANUEL J. SENN, M.D.

CHICAGO.

The automatic tissue forceps which I have devised, will be found to be an instrument of great utility in operative work and also one of precision. It is made of English steel, and consists of two blades which terminate in teeth. Midway between the extremities of the blades is the catch, which locks and unlocks automatically, synchronously with the grasp or release of tissues.

The instrument is operated with the thumb and index finger of the left hand with the same ease as in the use of the ordinary tissue forceps. Pressure sufficient simply to pick up the tissues is all the force required to lock the blades. This is at a minimum, as the blades possess great elasticity and consequently accommodate themselves to the "bite" of tissue, whether large or small.

To disengage the blades and release the grip, simply give them another gentle squeeze, when the catch unlocks.

This forceps possesses several advantages. In tedious dissecting, the thumb and index finger do not become fatigued, as the case with the ordinary forceps. During an operation, if the hands are necessary to manipulate some other instrument meantime, the forceps can be dropped with its "bite" of tissue intact and ready for subsequent dissection. The mind of the operator or assistant does not have to be con-

stantly concentrated on the instrument in order to insure its hold, the catch fulfilling that office.

The instrument was manufactured for me by Messrs. Chas. Truax, Greene & Co., Chicago.

## SOCIETY PROCEEDINGS.

### Chicago Pathological Society.

*Regular Monthly Meeting, Nov. 11, 1894.*

RANDOLPH N. HALL, President, in the chair.

DR. J. B. HERRICK reported a case of

#### GRAVE ANEMIA.

for which no other cause could be assigned than a severe nervous shock following an injury to the spine. The patient was a woman, 63 years of age, always in good health up to one year ago, leading an active busy life. There was no hereditary taint; no history or evidence of syphilis. In November, 1893, she fell to the sidewalk, hurting her back and left side; she walked home, but almost immediately after this injury became weak, physically and mentally. The legs began to bloat; she easily became dizzy, had fainting spells, was unable to walk for any great distance; became pale. Notwithstanding this, the appetite remained good. The bowels were somewhat constipated. She was admitted to the Presbyterian Hospital. Her complaint of vague pains, of weakness of the arms and legs, of mental deterioration, for all of which she assigned the injury as the efficient cause, coupled with the fact that there could be discovered no evidences of organic lesion to account for such phenomena, and also with the fact that she referred often to a \$2,000 accident insurance claim which she had placed in the hands of a lawyer for collection, led to a suspicion of exaggeration of symptoms, as in traumatic neurosis or railway spine, if not to a suspicion of malingering. The increasing pallor of the skin led later to an investigation of the blood and a more thorough examination of the patient.

The skin was yellowish-white, dry; panniculus adiposus scanty; patient talked slowly; moved hands and legs slowly; seemed weak, unable to walk or stand unsupported; complained of dizziness on being put in the erect posture. Numerous retinal hemorrhages in either eye. Lungs negative; systolic hemic murmur over heart; systolic hum over vessels of the neck; abdomen flabby; stomach resonance apparently increased in extent; stomach when inflated with air apparently enlarged; lower extremities, rectum, pelvic organs, bones, negative. Stomach contents show no free hydrochloric acid, no mucus, no remains of previous meal. There was no vomiting; no disturbance of nervous system. Urine 1012, acid; no albumin, no sugar, no formed elements; amount from thirty to fifty ounces; solids, 660 grains. Blood pale; marked poikilocytosis, microcytes and macrocytes, a few normoblasts, and megaloblasts; leucocytes relatively increased, particularly the lymphocytes. Red corpuscles 666,666; hemoglobin (Fleischl) 25 per cent. Temperature varying during two months of observation from subnormal to 102 degrees. Diagnosis: Pernicious anemia; cause, probably nervous shock consequent upon injury. Atrophy of stomach not positively excluded. Dilatation of the stomach believed to be due to atonic condition of muscular wall consequent upon severe anemia. Dr. Herrick recalled two cases of nervous disease, one a case of cerebral hemorrhage with aphasia and hemiplegia, one a case of sunstroke with marked cerebral symptoms, in which profound and fatal anemia had resulted. He also cited cases reported by others, as, for instance, Curtin, Musser, Schüle, Brigidi, Pokrowski, and others, in which profound—and in many instances fatal—anemia had followed organic disease of the nervous system, or in some instances

severe mental strain or shock. The patient had recently been put upon Fowler's solution, and later developments would, it was hoped, clear up one or two very interesting but as yet misty points. The report had been made perhaps a little prematurely, yet the occasion seemed so peculiarly fitting when other cases of diseases of the blood were to be brought to the attention of the Society, that he had ventured to bring the case thus early to the attention of the members.

VIDA A. LATHAM, F.R.M.S., D.D.S., presented a

#### REPORT OF A CASE OF LEUKEMIA.

Mrs. X., age 52; nativity, Welsh; occupation, housewife. Previous history: Patient has been married for a number of years; has had no children. The family lived in easy circumstances. The patient said she had malaria (?) at school during childhood, and it was prevalent where she lived in the State of Ohio. Duration of illness: General malaise and indifferent bad feelings for one year; she only noticed the enlargement of abdomen three months previous to her death. Clinical signs and symptoms. Night sweats with some temperature of slight degree, usually below 100 degrees, only once rising to 103 degrees. The kidneys were not affected, neither were the liver nor lymphatic glands enlarged.

The bones were not tender or painful. Emaciation was marked, as was the pallor of the face and skin. Some ascites and edema occurred shortly before death. The apex beat was displaced upward. The diaphragm was pushed upward.

The spleen was hard, and extended to within two inches of the right anterior iliac spine, about on a level with it, also across the hypogastric, umbilical and left inguinal regions, the notch of the spleen being about two inches to the left of the umbilicus at its level. There was a marked bulging between the left twelfth rib and the iliac crest and complete dullness on percussion in the left lumbar region posteriorly. There was obstruction of the intestines at one time, but her main symptoms were due to pressure—constipation, dyspnea and pain. This patient lived in the lowest part of A—, where the soil is always wet and drainage poor. During all her sickness—over a year—the street was dug up, for the building of a very deep outlying sewer. There were no other similar cases known. The blood which I examined through the kindness of Dr. Mary J. Kearsley, was spread on covers and examined by various methods, using dry air, fixing by heating on a copper plate, bichlorid of mercury, ether and absolute alcohol, chloroform, and staining in alcoholic eosin, counterstaining with methyl blue, methyl green, Rieder's method of eosin carbol glycerin and Delafield's hematoxylin, Czenzynski's stain, Ehrlich's hematoxylin and eosin, Ehrlich's Biondi triple stain, etc. The following forms were met with: Lymphocytes, especially the polynuclear kind, myelocytes, many with neutrophile granules, eosinophiles and very large mononuclear leucocytes. The red blood cells were paler than normal and variable in size. The proportions were one leucocyte to seventeen red blood cells.

About a month afterwards, I made another examination at the bedside with Dr. Kearsley. The blood with Gower's hemocytometer gave the red cells as 2,000,000 per centimeter or .40 of the normal, taking in each examination 1:600 as the normal blood ratio between red cells and leucocytes.

Hemoglobin with Fleischl's hemometer 18 per cent., taking 85 per cent. as the normal estimate.

The blood was very pale, but greasy, resembling marrow in the way it spread when trying to make the films. Cultures were also made, and round colonies of streptococci

which grew best on glycerin gelatin-agar were obtained. One tube of glycerin agar gave a streaked growth of a grayish-white color, covers from which showed a minute bacillus. The further study was prevented unfortunately through the patient falling into the hands of a quack who suggested an operation as offering a cure. The patient was removed to a private hospital in spite of the family physician's advice, and soon after her arrival the rectal anus was dilated and the patient died in a few hours from uncontrollable hemorrhage of the bowels.

Dr. E. H. TIXEN read a

#### REPORT OF CASES OF LEUKEMIA AND PERNICIOUS ANEMIA.

In the following reports I have to thank Dr. Jas. B. Herrick for valuable suggestions, Dr. E. R. LeCount for aid in the pathologic work, and Dr. D. D. Bishop for excellent instruction:

*Case 1. Leukemia.*—M. K., age 43, female, married. Born in Ireland and lived there until five years ago and since then has lived in America. Menstruated at 16 and was perfectly normal until six months ago, since when it has been absent. Had children's diseases when small. Denies venereal history. Was married at 31; had a miscarriage at third month of pregnancy without any known cause. There was no subsequent pregnancy. Father died at 50 years of age, of some acute illness. Mother died at 30 years of age in confinement. One brother is living and 40 years of age. No brother or sister dead.

*Present Illness.*—Ten months ago was attacked with a sharp and quite severe pain in the left iliac region which persisted for three days, then disappeared only to return again in three weeks. For last two months has been free from pain. During past three weeks, feet and legs have been swollen. She complains only of weakness. There is no pain, vomiting, nausea or fever. Bowels are regular.

*Physical Examination.*—A woman of slight stature, fair complexion, marked paleness of visible mucous membranes and finger nails. Tongue slightly coated. Eyes and ears negative; pulse 166; temperature 102.2; respiration 24. Chest, lungs and heart negative. Liver dullness extends from fifth rib in nipple line to one inch below costal arch. Tenderness over the sternum. Abdomen: There is marked prominence of the left lumbar and epigastric regions. A mass can be felt occupying these regions, its anterior border extending in a curvilinear direction from the eleventh rib downward to the umbilicus, encroaching on the hypogastrium. Over this mass there is dullness, extending to the inferior angle of the left scapula posteriorly. A coarse friction sound is heard over the upper part of the dull area. Vaginal examination revealed nothing of interest. The feet and legs are edematous.

*Urinalysis.*—Specific gravity, 1015; no albumen, no sugar; microscopically negative.

One month later, July 20, 1894, an examination of the blood showed 50 per cent. hemoglobin. An increase in the white corpuscles was noted, but no count made. On Sept. 5 1894, the blood was examined and gave hemoglobin 40 per cent.; red corpuscles 1,650,000 per cmm.; white corpuscles 184,000 per cmm.

*Stained Blood Preparations.*—Cover-glass smears were fixed by heat, absolute alcohol and ether, absolute alcohol, and corrosive sublimate, and then stained by means of solutions of eosin, methylene-blue, dahlia, safranin and Ehrlich's Biondi triple stain. As regards the red cells, there was a variety of sizes varying from normal to twice the normal size. They assumed a variety of shapes—poikilocytosis. There were nucleated red cells of the normal size (normoblasts), and larger ones (megablasts), and many contained more than one nucleus. Free nuclei were seen, having escaped from

the corpuscles and at first appearing as leucocytes. There were a few polychromatophilics. The differential count of the white corpuscles gave small mononuclears 2 per cent., large mononuclears 7 per cent., polynuclear neutrophils 50 per cent., eosinophiles 5 per cent., and myelocytes 36 per cent.

On Sept. 26, 1894, a systolic murmur was detected over the base of the heart to the left of the sternum. On Oct. 11, 1894, the blood examination gave hemoglobin 30 per cent.; red corpuscles 1,134,000 per cmm.; white corpuscles 644,000 per cmm. On Oct. 12, 1894, she rapidly became worse and died at 7 P.M. At no time after admission did she have a temperature above 101.4 F. by mouth.

#### NECROPSY.

Twenty hours after death. Emaciation quite marked. Heart was negative as to valves and walls. Its auricles contained large light chocolate-colored clots. Lungs were negative except an area of broncho-pneumonia in the right middle lobe. There were firm adhesions about the spleen and liver; liver weighed 3,650 grams. Its section was through a fairly resistant though friable tissue; its lobules were indistinct having dark centers and light peripheries. Bile passages were patent. The kidneys together weighed 350 grams. There was a small infarct in the right one, but otherwise they were negative. The spleen weighed 1,850 grams, and measured 23x11x13x10x7 cms. There was a scar on the right lower border (4x2½ cm.) limited to the capsule. Over the upper and posterior part was a yellow area of depressed tissue measuring 10x5 cms. On section it was seen to extend into the spleen a distance of three cm. There was a similar but smaller area on the anterior aspect of the organ. These areas on section had the appearance of cream cheese. Otherwise the section of the organ was uniformly grayish-red. The bone marrow was pale and the bone soft.

*Microscopic Examination.*—Tissues were hardened in alcohol, imbedded in celloidin, and the sections were stained with hematoxylin and eosin, also with eosin and methylene blue. Pancreas: Great excess of leucocytes in vessels, none in the tissues. Liver has an alveolated appearance, the network composed of rows of liver cells, the meshes of capillaries in a state of extreme dilatation. The relation of liver cells to capillaries is as 1 to 2. All the capillaries and smaller vessels are completely filled with leucocytes, no red cells or remains of red cells being seen. There is pigmentation of liver cells with brown pigment, also there are hemosiderine granules about the central veins. The liver cells show degenerative changes to a small extent, staining markedly with eosin, and cells being seen with well stained, faintly stained and unstained nuclei. In areas there is marked compression of liver cells, the rows of cells being no thicker than sixteen micromillimeters and lying between dilated capillaries. The portal sheath connective tissue and vessel walls are invaded by leucocytes which stain deeply with hematoxylin. Kidneys: There is a slight brown pigmentation of under layer of capsule. The glomeruli fill the capsules, as a rule, and contain an excess of nuclear elements. This excess is apparently due to small irregular darkly staining cells. In the capillaries there is a condition corresponding to that in the liver, the tubules being compressed and rarely possessing a lumen. There are a few degenerative changes in the epithelium of the convoluted tubules. There is also an excess of leucocytes in the larger vessels, and some of the medium-sized vessels are filled to distension with leucocytes. There are no leucocytes in the collecting tubules. Excess of connective tissue in the pyramids in the shape of hyaline intertubular framework is noticed. Spleen: There is an increase of the connective tissue confined mostly to the finer network. The capsule is

thickened and just beneath it the tissue contains brown pigment. Malpighian bodies are few and smaller than normal. There is almost an entire absence of red blood corpuscles. There is a small amount of golden brown pigment in the form of granules lying in the connective tissue framework and at times in the spaces or in the cells.

**Lungs:** There are areas of tissue where the spaces are entirely filled with darkly staining cells, other areas in which the lung structure has entirely disappeared, and in still others the alveolar walls can be seen. Between such areas there are regions of compressed and deformed alveoli, filled with a faintly staining granular substance. In the areas of consolidation the cells are large and show no signs of fragmentation or degeneration. In the areas where alveolar walls still remain, the alveolar contents are mostly polynuclear leucocytes with here and there in the peripheries large cells with a single nucleus. The alveoli with granular contents show heavier walls than usual, due to the dilated capillaries. Bronchioles when seen are filled with granular homogeneous material in which are large numbers of leucocytes.

**Heart muscle:** It presents a peculiar appearance due to rows of nuclei separating the muscle fibers. The muscle fibers are compressed by dilated capillaries. Poor staining of the muscle is marked and general. In many places there are alternate rows of muscle fibers and leucocytes, frequently the row of fibers is only one or two fibers wide.

*Case 2. Leukemia.*—W. T., age 19; male; teamster. Father died of "paralysis," otherwise family history is negative. Venereal history denied. Uses alcohol moderately. One month ago he received an injury to his right leg, which was followed by suppuration. An incision was made and there is still an open wound. Four days before admission had an attack of diarrhea and vomiting. Has no pain. Has shortness of breath and palpitation of the heart.

**Physical Examination.**—Body is emaciated, conjunctivæ injected, tongue slightly coated and moist, lips and gums pale. Chest: Lungs are negative. The heart is very slightly enlarged and a blowing systolic murmur is heard just to the left of the sternum in the third interspace which is not transmitted. Abdomen: The liver dullness extends in the mammillary line from the sixth rib to one inch below costal arch. Spleen is easily palpable, extending forward to left parasternal line at the costal arch and below one inch below the umbilicus. A small notch is felt in its anterior border. It is moved by posterior pressure. No enlarged glands; no tenderness over bones. Blood examination gave red corpuscles 3,064,000 per cmm., white corpuscles 848,000 per cmm. The hemoglobin was not estimated. The differential count of the white corpuscles gave small mononuclears 3 per cent., large mononuclears 8 per cent., polynuclear neutrophils 60 per cent., eosinophiles 6 per cent., and myelocytes 23 per cent.

A few days later he left the hospital and passed from observation.

*Case 3. Leukemia.*—H. H., age 37; male; farmer; admitted Nov. 1, 1894. Family history good. Born and raised on a farm in Wisconsin. Does not use alcohol or tobacco. Venereal history denied. Had typhoid fever twelve years ago, pneumonia three years ago. One year ago was kicked in ribs over spleen. Present illness: For some time he has complained of weakness and inability to endure heat. Three weeks ago was attacked with headache, weakness, and sensation of fever sufficient to cause him to stay in bed. A few days later he noticed a swelling in the abdomen, and a yellowness of the skin. He now complains of shortness of breath at times and palpitation of the heart. He has had no hemorrhages.

**Physical Examination.**—Body fairly well nourished; con-

junctivæ slightly yellowish; tongue pale and coated. Skin has a yellowish tint and on cheeks are several petechiæ. Heart, not enlarged. A blowing systolic murmur heard equally well in all areas and not transmitted. Lungs were negative. Spleen, extends from eighth rib at inferior angle of the scapula to the median line in front and one inch above the umbilicus, with a distinct notch just above the umbilicus. Liver extends from sixth rib to one inch below costal arch in mammillary line. All the lymphatic glands are enlarged, the post-cervical exhibiting the enlargement to the greatest degree.

**Blood Examination** shows hemoglobin 20 per cent., red corpuscles 1,050,000 per cmm.; white corpuscles 108,324 per cmm. The differential count of the leucocytes gives small mononuclear 3 per cent., large mononuclear 8 per cent., polynuclear neutrophils 64 per cent., eosinophiles 6 per cent., and myelocytes 19 per cent.

He left the hospital in a short time and further study became impossible.

*Case 4. Pernicious Anemia.*—M. O., age 50; female, single; Admitted Oct. 23, 1893. Mother died of stomach trouble. Several of the family suffered from rheumatism. Menstruated at 16, and was always regular until present attack when they stopped. Does not use alcohol. Venereal history denied. Has had no previous illness. Present illness: Four months before admission she suffered from headache, pain in the epigastrium especially following the ingestion of food, anorexia, vomiting, diarrhea, edema of the legs, feet and eyelids.

**Physical Examination.**—Nourishment is poor; skin a waxy color; tongue moist; all visible mucous membranes pale. Lungs are negative. Heart. Area of dullness is increased; apex beat is two inches below nipple in nipple line. A murmur, systolic in time, is heard at the apex and transmitted to the left axilla. Liver dullness begins in fourth interspace and extends to border of costal arch. There is tenderness in the epigastrium. Feet and legs are edematous. Pulse 104, temperature 99.4, respiration 20.

**Urinalysis.**—Dark and cloudy, specific gravity 1027; considerable albumen. No casts found. A little later granular casts were found. During the year from admission until Oct. 1, 1894, her symptoms were those resulting from her nephritis, but they improved with the improvement in the renal condition. The latter part of the year, albumen and casts were absent, except for a short time before death when a trace of albumen was present. During the year there was considerable trouble referred to the stomach, especially after eating.

**Physical Examination** on Oct. 16, 1894: Lungs negative. Heart, the apex is in the fifth interspace in the anterior axillary line. Liver dullness extends a little below costal border. There is extreme tenderness in the region of the gall bladder also in the epigastrium. Spleen is not palpable. Eyes: Retina is pale, otherwise negative. Gastric contents after test breakfast revealed no hydrochloric acid, very slow digestion, great excess of mucus.

**Urinalysis.**—Twenty-four hour specimen—clear, specific gravity 1010, slight trace of albumen, no casts, total solids, 297 grains.

**Examination of Blood** shows hemoglobin 30 per cent., red corpuscles 738,000 per cmm., white corpuscles 8,000 per cmm.

In stained preparations were noted well marked poikilocytosis, and large and small nucleated red corpuscles. There was a slight increase in the white corpuscles.

The patient gradually grew weaker and died Nov. 7, 1894.

#### NECROPSY.

Peritoneal, pleural and pericardial cavities filled with a transparent yellowish fluid. There is slight hypertrophy of left ventricle and a little thickening of the aortic

valves at their bases and of the mitral valves at their free margins. The lungs were negative. The liver weighs 1900 grms. and the surface is granular at its edges. The cut surface is granular, the lobules having pale centers and dark peripheries. There are no large bands of connective tissue. Gall passages are patent.

*The Spleen* is slightly enlarged, its cut surface being mottled from the presence of perceptible whitish Malpighian bodies. The kidneys showed marked atrophy of the cortex with some yellowish streaks, the glomeruli not being visible.

*The Stomach* has no rugæ, the level of the mucous membrane is below that of the esophagus, and is very thin.

*The Intestines* were negative. There was injection of the internal layer of the dura mater, and a covering of fibrinous exudate. There was atrophy of the cerebral convolutions. The general muscles were very pale and flabby.

The microscopic examination is left for a later report.

#### DISCUSSION.

DR. I. N. DANFORTH—I can add nothing to what I have stated in a paper which has been published lately with reference to pernicious anemia. I will say, however, that I am experimenting on the treatment of pernicious anemia, or rather anemia of various types, in my wards in St. Luke's Hospital, and hope by-and-by to report the results, but for the present I have said everything I know in the paper already published. I have been greatly interested in the papers tonight, and as the papers by these younger men were being read I was thinking how we have moved along in the past ten years. It is about ten years ago when this Society met in my parlors, about half a dozen of us, to bury the Society, to hold a funeral service over it, but instead of doing that they elected me President, and from that time the Society began to flourish as several of the members rallied around me, and it has now grown to be this large and flourishing body. The papers read tonight evidence the growth of the Society and it is very pleasant indeed to me to meet these younger men, to see how they are pushing things along and to listen to these learned and exhaustive papers on leukemia and the anemias. The writers of the papers did not say anything about the presence or absence of the plasmodium of malaria. I suppose that the blood was examined for that; if not, I should regard it as rather an oversight and would suggest that it be done, because I believe it to be a very important factor in the diagnosis. But the most important thing in practice is the treatment of these anemic cases.

DR. G. F. BUTLER—The pathology and diagnosis of this disease has been thoroughly discussed, and as the natural bent of my mind is towards the therapeutic side of the case I will only discuss the therapy. From recent literature I have read on the subject of pernicious anemia and leukemia, it is evident to my mind that bone marrow now leads the procession in the medicaments for pernicious anemia. Whenever a new remedy is announced, the agent is applied to the treatment of disease and a verdict often rendered which gives an erroneous impression as to its true value. The first formulas are often given forth by physicians who are more enthusiastic than logical and more sensational than exact. So numerous are the fallacies of experiment and clinical experience that the painstaking therapist must read carefully the testimony in all of these cases, and examine with the same jealous care into the efficiency of the new remedy as the old. We all know that a true understanding of the therapeutic art must be upon an exact etiology and pathology, but at the same time a great many empirical facts are well founded upon professional experience and these well established facts should not be overlooked. I am therefore not prepared to disparage bone marrow as a remedy in pernicious anemia, but I would ask, Is the curative

value of bone marrow a well established fact in the treatment of pernicious anemia, and indeed I would ask if there is anything in the recent literature on the treatment of pernicious anemia or of leukemia that is new? In every case I have read about, arsenic has been given in conjunction with bone marrow. We know that arsenic has been a valued remedy in the treatment of anemia for many years and there are many recorded cases of recovery under its use. Is it not quite possible that these reported cases of recovery have been due as much to the arsenic as the bone marrow, and even more? When a genuine case of pernicious anemia continues to rapidly improve upon bone marrow alone, then I will be ready to class it as a valuable remedy in this disease; when bone marrow has to its credit as large a number of recoveries as arsenic, then I will be ready to accord to it the virtues claimed for it by its enthusiastic supporters. Since bone marrow has struck Chicago there have been more cases of pernicious anemia reported than ever before in its history. I have found, not in my own practice, but by information from other doctors, a number of cases of anemia this last week, which some have claimed were pernicious, that have rapidly improved under the administration of bone marrow, and arsenic with iron on the side. I have had quite a number of cases of simple anemia and chlorosis that improved upon a mixture of the three chlorids of mercury, iron and arsenic, with codliver oil, and it seems to me if I had given kumyss with the other remedies I might have boomed that in connection with this disease. I am inclined to think that kumyss is as good a remedy as bone marrow. It is nutritious, easily digested and an intestinal antiseptic, and if given in connection with arsenic and good hygienic treatment it is a combination which will prove as useful as bone marrow and arsenic. I think thus far there has not been a case treated by bone marrow alone, at least I have not learned of any, and I am inclined to think that this remedy is perhaps of very little more value in the treatment of this disease than the so-called animal extracts which have been recently introduced. These extracts, given with the view of curing disease, appear to me to be about as sensible as to attempt to increase the weight and fiber of a tree by manuring it with fresh sawdust. I think bone marrow nothing more than a nutrient fat and it possesses no more advantage than cream or codliver oil. It seems preposterous to me, even admitting for the sake of argument that the structural disturbance of the bone marrow is the origin of the disease, that by eating calves' or hog's marrow it will escape the gastro-intestinal ferments and penetrate the bone substance and make good rich blood. On the supposition that the spleen is the seat of the formation of the red blood corpuscles, I would not be surprised to see calves' spleens given in whisky and glycerin. In conclusion, I would say that with arsenic, the best remedy we have to-day, we often fail because we do not push it to the limit. In my opinion it should be given in medium doses of Fowler's solution and should be increased in half drop doses until decided symptoms of arsenical poisoning appear, then the administration should be stopped for a time. Combined with a laxative we may continue to give this valuable drug with decided benefit in some cases.

DR. D. R. BROWER—I desire to say a word in emphasis of a point made in the paper of Dr. Herrick. This point I would emphasize, as it is of vast importance; that is, the factor of mental disturbance, of shock. The last case of pernicious anemia I saw, was a young woman from Wisconsin. A shock was the beginning of the disease. She was in a railway carriage and was severely shaken up, but with no particular marks of injury that could be found at the time. Then her health began to fail and six or eight months after the accident she came here, when a diagnosis of pernicious anemia

was made, and like all the others, she passed to the other side. I have never yet seen a case of pernicious anemia recover, even after protracted doses of arsenic, or with other treatment. Cases of ordinary anemia that are so common, are frequently the result of shock and mental disturbance. I saw a case last spring in which Fleischl's hemometer gave 20 per cent. of hemoglobin. It was a young man who was troubled about his examinations soon to occur, and his blood deteriorated until it made a record of 20 per cent. There was nothing else but his intense mental worry and excitement and feeling of apprehension. The point I wished to make was to emphasize Dr. Herrick's suggestion of shock and mental disturbance having very much to do with the causation of many of these cases.

DR. H. N. MOYER—I was, fortunately for myself, invited by Dr. Herrick to see his very interesting case and I had the privilege of going over with him very carefully the clinical history and making an examination of the nervous functions. It was to me a case of rare interest because it was the first one I had seen of so grave an anemia apparently associated with nervous shock. The literature of the subject while in a way meager, in another way is comparatively rich; the older writers contain many references to anemia of a nervous origin, *marasmus nervosa*, it was termed, and they seemed to recognize very clearly the etiology factor in many of these cases. These older observations have not the value they would have, if the present method of examining the blood had been in vogue. As to the relation in Dr. Herrick's case, between the disease and injury, as he has pointed out in his paper, all other things are not excluded and they probably can not be unless the patient should die. Regarding the treatment of pernicious anemia which has been mentioned, I would not agree with Dr. Butler as to the inefficiency of bone marrow. I do not think it has been demonstrated and I do not think that one can *ex cathedra* say it will not be of benefit. He says that extracts of tissues, the spinal cord, muscles, heart and other parts have failed. That is true, but it is not true of all extracts; there have been extracts of glands used that have proved to be of great value. I think the value of the thyroid extract in the treatment of myxœdema is established without doubt, and it is possible that in bone marrow we have a structure analogous to glandular structure, a secretion of cells going on which is of great therapeutic value. I agree heartily that arsenic is one of the very best remedies to employ in these anemias, particularly the forms that result secondarily to some trouble with the nervous system. But the method I have employed is the use of arsenic under the skin. It is very much less toxic than when given by the mouth and enormous doses can be used in this way in absolute safety. It is my common practice to give an initial tory injection with an equivalent of 22 minims of Fowler's solution, and I frequently reach an equivalent of 75 and in some cases 100 minims, 1 grain of arsenite of potassium in a single dose, without toxic symptoms. These large doses of arsenic act more efficiently than when given by the mouth. The liver has a strong elective affinity for arsenic and it is absorbed through the alimentary canal with great difficulty. The toxic action expends itself almost wholly upon the stomach and upper end of the intestine. The hypodermic use of arsenic acts the same as injections of mercury in specific disease; it is distributed immediately to all parts of the system by the circulation. I have estimated the toxicity of arsenic to be five or ten times less when administered under the skin than when given by the mouth. The arsenite of sodium is free from any objection; it never causes the least sign of irritation. Fowler's solution can not be used in this way as it almost invariably causes an irritation and very frequently an abscess, but the arsenite of sodium may

be injected, so far as local symptoms are concerned, with the same impunity as water.

DR. E. R. LECOUNT—With reference to the specimens of Dr. Tinen, I have to say that the heart muscle in the case of leukemia, presented a very peculiar appearance under the microscope. I did not see it in the fresh specimen. The heart muscle fibers were marked out by the leucocytic invasion of the capillaries between the fibers, very much as the capillaries in the liver were filled with leucocytes dividing the rows of cells. Although I had seen microscopic specimens of cases of leukemia before, this condition of the heart muscle was the most extensive and remarkable I have seen. In the case of pernicious anemia there was a distinct atrophy of the mucous membrane of the stomach. This could be easily demonstrated by taking a portion of the mucous membrane and spreading it with the peritoneal surface down upon the hand, and lightly moving the mucous membrane on the deeper layers, it being united to the deeper layers by a loose submucous tissue which allows ready motion. It could thus be seen that there was nothing there but a thin membrane making up the mucous coat.

DR. F. J. DEWEY—In connection with Dr. Herrick's paper and the influence of nervous shock in anemia, I recall a case I have under treatment at present, a young lady stenographer who works in one of the courts. Whether this anemia is pernicious or not, I am not able to say, but that the excitement of her occupation has a great deal to do with her condition I have no doubt. She is taking testimony from different lawyers and it must be absolutely correct and she must be able to read it at a moment's notice during a controversy. After she has had a most exciting time in court she always gets worse. She exhibits all the characteristic symptoms which have been brought out in the papers tonight, and it occurred to me, while Dr. Herrick was reading his paper that this nervous excitement was the cause of her trouble.

DR. J. M. PATTON—In connection with the etiology of pernicious anemia, Dr. Herrick mentions one case where sunstroke was supposed to have been the cause. Last summer I had under my care for a short time a woman 58 years of age who had always been in perfect health, had always had a good home, with every comfort and the most hygienic surroundings. She had never had any nervous troubles or shocks that could be found out, with one exception. Three years ago she suffered from sunstroke while in California. Last summer she came here to attend the World's Fair and shortly after her arrival she came under my care for hemorrhage from the gums. She stated at that time that she had not been very well for two years. She had a bad appetite, a good deal of gastric distress, the skin was of a light lemon color, the conjunctiva was pale and slightly injected, the retina looked normal. She had no trouble with the sight and beyond the gastric disturbance and trouble with the gums she knew of nothing from which she suffered. About a week after that she had a severe hemorrhage from the nose. These hemorrhages continued several days and the anemic condition seemed to be rapidly advancing. An examination of the blood at that time showed a very marked decrease in the number of red corpuscles and also of the hemoglobin. She gradually grew worse and died about three weeks after coming under my care. I mention this case because of the almost complete history of a number of years with absolutely nothing that could affect her in any way except this sunstroke.

DR. E. A. TINEN—I have to say that malaria was excluded from the four cases reported. The case of glandular leukemia had a history of injury over the spine. Taken in connection with Dr. Herrick's case it seems worth while to take note of that.

DR. J. B. HERRICK—It seems evident from the discussion that there is no clinical distinction between cases of primary and secondary anemia and chlorosis. Many of the cases of anemia that recover could not be called pernicious. There is a great distinction between chlorosis and pernicious anemia, that was merely hinted at in the paper, but in the examination of the blood no one should hesitate to recognize a case of chlorosis. Chlorosis is first of all a reduction in hemoglobin. Some patients are very pale, suffer from syncope and from most marked palpitation. Some who are dizzy and incapacitated for work may have a normal number of red blood corpuscles or the reduction be very slight as compared to the enormous reduction in the hemoglobin. In a case I saw about four years ago there were 34,500,000 red blood corpuscles and only 20 per cent. of hemoglobin, an enormous reduction. That was a case of chlorosis. In pernicious anemia, on the contrary, the marked reduction is in the number of red blood corpuscles; sometimes we find one or two million, and even less than one million; in one case it was 143,000. Many cases are reported where there is less than half a million red blood corpuscles found, but the proportion of hemoglobin is great. In the case I reported there was 13 per cent. of red blood corpuscles and 25 per cent. of hemoglobin. If it was a case of chlorosis there would probably be 25 per cent. of red blood corpuscles and 13 per cent. of hemoglobin. So I think many cases of anemia that recover can not be set down as pernicious unless a careful examination has been made. Chlorosis will recover with proper hygiene, the administration of arsenic and iron; anemia, secondary to some gastric disturbance may recover; anemia secondary to renal disturbance may recover, at least temporarily, but a clinical distinction should be made between cases of pernicious anemia and chlorosis, and ordinary secondary anemia. Recoveries from pernicious anemia seem to me to warrant us in excluding that term, "pernicious," which practically implies fatality. It is unquestionably true that there are cases which, after a careful examination are found to be clinically perfect as primary essential anemias, recover. Osler, out of twenty cases, has had two recoveries, the patients living ten or fifteen years. Some of Osler's cases which apparently recovered, died four or five years afterward, so that a fatal result may come from a relapse.

DR. V. A. LATHAM—In the cases of leukemia I have seen, both in this country and in England, most of them had a malarial history. In the case reported to-night the plasmodium was carefully looked for but not found. In some recent researches I was looking over, I was rather astonished to note the rarity of leukemia. In some statistics gathered by prominent German and English authorities there was only 1 case in 60,000.

DR. D. D. BISHOP, Chicago, read a paper on

#### STAINED BLOOD PREPARATIONS.

In a routine examination of the blood as performed in the hospitals to which the laboratory staff of Rush Medical College has access, the following observations are always made:

1. A count of the number of red and white blood corpuscles per cubic millimeter.

2. An estimation of the percentage of hemoglobin present.

3. A cover-slip preparation of fresh blood is examined concerning the following possible conditions:

(a). Apparent changes in the color of the red blood corpuscles.

(b). Changes in the size of the red blood corpuscles, noting whether there be present corpuscles much smaller than normal, microcytes, or those larger than normal, macrocytes.

(c). Changes in the form of the red corpuscles, poikilocytes.

(d). The presence or absence of Laveran's organisms of malaria.

(e). A number of spread cover-slips are then taken and preserved for subsequent examination by the color-test as recommended by Ehrlich.

The Thoma-Zeiss blood counting apparatus is used in estimating the corpuscles; with this the red corpuscles are easily counted and with almost absolute accuracy. The limit of error with careful observers being placed at 2,000 a cubic millimeter. If there be leucocytosis, the white corpuscles may be counted in the same manner as the colored, but if the leucocytes be few, Toison's solution may be used as a diluent in place of the salt solution ordinarily used. By this means the nuclei of the leucocytes will be stained blue and may be easily separated from the red corpuscles. Again a  $\frac{1}{2}$  per cent. acetic acid solution may replace the salt solution when the red corpuscles will be destroyed and only the leucocytes remain.

Ehrlich's color test has attracted much attention of late years, for by its use a great deal has been added to the knowledge of the histology and pathology of the blood. In making this test the following methods are pursued:

The skin of the finger tip or the lobe of the ear is well washed with sterilized water, and pricked with a needle or fine lancet. The first few drops of blood are wiped away and a small drop as soon as it has escaped from the puncture is received upon a perfectly clean cover-slip held in forceps. Another slip, also held in forceps, is dropped immediately upon the first one so that the drop of blood may spread out in a thin layer between the two. They are then quickly but carefully separated by a sliding motion without pulling them asunder, and allowed to dry in the air. No delay should occur in the manipulations lest the corpuscles become crenated. Before staining, the dry slips must be fixed, by which means the corpuscles are firmly glued to the glass and the hemoglobin rendered unabsorbable by the dyes. Fixing is best done by Ehrlich's method, the slips being heated upon a copper bar to 120 degrees C., for one to two hours. Another easily applied and quite satisfactory method is to place them in either absolute alcohol alone or absolute alcohol and sulphuric ether, equal parts, for from one-half to twelve hours. The staining process: Ehrlich has divided the dyes used into three varieties, "acid," "basic," and "neutral." An acid dye is one in which the acid portion of the compound is the active principle in the staining process, an example being eosin, while a basic dye is one in which the basic side is more active, as methylene blue. A neutral dye is one formed by mixing previously prepared solutions of acid and basic dyes with the acid slightly in excess; an example being a mixture of acid fuchsine and hematoxylin solutions. In general, a basic dye stains nuclei while an acid dye stains the cell body. We shall see, however, that certain granulations found in the protoplasm of the cell body of leucocytes act in a definite manner toward the different dyes, and upon this the classification of leucocytes as given us by Ehrlich is based. The study of the varieties of leucocytes furnishes the greatest fascination of any part of this work, for by this classification there is spread out before the clinician a field from which much has been added to the more careful diagnosis of disease.

Fixed specimens of blood may be stained for five minutes or longer in a fairly strong, aqueous solution of eosin, washed, dried between two layers of filter paper, and again stained for three to five minutes in a concentrated aqueous solution of methylene blue, washed, dried as before, mounted in Canada balsam and examined with a one-twelfth oil immersion lens. In such a specimen a very interesting picture will be seen. Of the leucocytes one sees the following:

1. Small leucocytes, a little smaller or a little larger than

a normal red corpuscle with a spherical nucleus nearly filling the cell and staining deeply with the "basic" dye. Some of these show only a slight rim of protoplasm about the nucleus, while others show quite an appreciable amount which may or may not be slightly tinged with the red "acid" dye. These, Ehrlich has called the small mononuclear leucocytes or lymphocytes. They form about 15 to 20 per cent. of all leucocytes in normal blood.

2. Leucocytes considerably larger than the last, also having a roundish, oval or ovoid nucleus, which stains fairly well with the "basic" dyes and shows a relatively well developed rim of protoplasm about the border. These he called the large mononuclear leucocytes.

3. Leucocytes, much like the last but showing an indentation in one border of the nucleus. Ehrlich believed these were in transition stage from the last variety to the polymorphous nucleus of the next, hence spoken of as transition forms. Forms 2 and 3 constituting 6 to 7 per cent. of all.

4. Leucocytes, somewhat smaller than the largest mononuclears, with a polyform nucleus, staining lightly with the basic dyes, while the fine granules in the protoplasmic body of the cell will be lightly tinged with the "acid" dye. These were called the polynuclear leucocytes and because the protoplasmic granules stained well with the "neutral" dyes they are spoken of as having neutrophilic granulations. They are often called neutrophils. The term, polynuclear, is misleading as it implies the presence of many nuclei in each corpuscle. This is not true as all leucocytes have but one nucleus. It is more proper to speak of them as leucocytes with polymorphous nuclei. These constitute 70 to 75 per cent. of all.

5. Leucocytes with polymorphous nuclei staining quite well with "basic" dyes and showing large rounded or ovoid granules in the protoplasm that stain dark red with "acid" (eosin) dyes, hence called eosinophiles. These granules always stain with the "acid" dyes and with no others. The eosinophiles constitute about 5 per cent. of all. Five different granulations behaving differently toward dyes have been described by Ehrlich, but as only three are found in human blood these only will be considered.

The eosinophilic or A—granulation is found only in the eosinophiles; the neutrophilic or E—granulation found in the majority of polynuclear leucocytes, and the B—granulation. The last is applied to those granules staining only with the "basic" dyes—basophilic. Such are found in the "mastzellen" of normal bone marrow.

The red blood corpuscles will be colored light red by the acid dyes and the blood platelets will also appear in small groups tinged with the same stain. If one uses the triple stain of Biondi-Ehrlich which contains orange G, methyl-green and acid fuchsin he may get the effect produced by an acid, basic, and neutral dye at one and the same time. For such work one may employ the stain prepared by Grübler in the powdered form and use a saturated solution in water 6 parts, alcohol 1 part, and glycerin  $\frac{1}{2}$  part. This should be left in contact with the specimen three to ten minutes, washed, dried and mounted in balsam. Here one finds the red corpuscles yellow from the orange G, the nuclei of the leucocytes, the nucleated red corpuscles green from the methyl-green, and the neutrophilic granulations violet. The eosinophilic granulations will be stained a dark red.

So much for the normal blood. As to the relations of these varieties to each other, and their origin, there are two views. Ehrlich, on the one hand, claims that the small mononuclear forms are derived from the lymph glands and have no developmental relation to the other forms, while the large mononuclears and polynuclears are derived from the spleen and bone marrow. The eosinophiles also having their ori-

gin in the bone marrow. He believes that from the large mononuclear forms the transitional and polynuclear leucocytes are developed. The polynuclears, he says, are the only variety that possess amoeboid movements, are oftenest found remote from the vessels, that they divide by karyokinesis, and perhaps by amitosis as well. This differs from the view held by Virchow that all other varieties are developed from the lymphocytes. Ouskow has lately supported this view, he having found upon examination of fresh juices from the blood forming organs, small mononuclear elements in not only the lymph glands but in the bone marrow. He believes karyokinesis occurs in the lymphocytes and continues up to the polynuclears, after which it can no longer occur. The tendency to-day is to accept this mode of development. Ouskow classifies the leucocytes as young, ripe and over-ripe forms corresponding respectively to Ehrlich's lymphocytes, large mononuclears, and polynuclears. If one examines stained smear preparations of bone marrow blood he finds several cells not seen in the circulating normal blood. These do appear, however, in certain diseases, in the circulation.

1. Of the red corpuscles one sees nucleated corpuscles of normal size, Ehrlich's normoblasts, again corpuscles considerably larger and nucleated, the megaloblasts of Ehrlich and Hayem. Their nuclei stain deeply with the basic dyes. These elements appear in the blood of pernicious anemia, the secondary grave anemias and leukemia. They are generally considered as rapidly developing young forms.

2. Large cells with a rounded or ovoid single fairly-staining nucleus, about the size of the large mononuclear leucocytes, but containing neutrophilic granulations—the myelocytes. These are of very infrequent occurrence in normal blood but are present in spleno-myelogenous leukemia.

3. The "mastzellen," much like the large mononuclear leucocytes, but showing coarse "basophilic" granulations in the protoplasm, are seen in bone marrow blood and in the circulating blood of spleno-myelogenous leukemia.

The application of the color test has been found of great service in determining the different varieties of the so-called blood diseases. It is only natural to expect that other important aids to diagnosis will be established as further accurate observations proceed. Already some important facts relative to the varieties of leucocytosis found in the different specific fevers have been discovered by the able researches of Ouskow and Khetagurow and confirmed by Thayer and others. The blood of several cases of malaria has been lately exhaustively studied by Billings, of Johns Hopkins Hospital, who has pointed out some very interesting and important facts relative to the leucocytes in that disease. It is to be hoped that we shall yet learn the true etiology of those diseases in which there are such profound blood changes, now so mysterious.

## Proceedings of the First Meeting of the American Academy of Railway Surgeons.

*Held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.*

*(Continued from page 94.)*

THIRD SESSION, FRIDAY, NOVEMBER 9, 8 P.M.

DR. H. J. MAYNARD in the chair.

The Committee on Constitution and By-Laws, through its chairman, Dr. C. K. Cole, made the following report, which was adopted at Chicago, Nov. 9, 1894:

## CONSTITUTION AND BY-LAWS OF THE AMERICAN ACADEMY OF RAILWAY SURGEONS.

### NAME.

1.—The name of this organization shall be the American Academy of Railway Surgeons.

### OBJECTS.

2.—The objects of the Academy shall be the improvement

and advancement of Railway Surgery by means of the study of the subject in general, and especially by the study and investigation of clinical, medico-legal and sanitary matters relating thereto; by the reading and discussion of papers in convention, and the cultivation of closer fraternal relations among those actively engaged in this special work.

#### MEMBERSHIP.

3.—The members of this organization shall be known as Fellows, and shall be divided into two classes, namely, Active and Honorary. The list of Active Fellows shall be limited to two hundred (200) Railway Surgeons, and shall be restricted to those in actual service as such at the time of their election.

No Fellow shall continue as an Active Fellow after having severed his connection with a railway company, but he may become an Honorary Fellow by a vote of the Academy as herein provided. Honorary Fellows shall have the same privileges as Active Fellows, excepting the right to vote, hold office and participate in the Executive Sessions.

The list of Honorary Fellows shall at no time exceed one hundred (100) and shall be composed of such surgeons and physicians, as may be elected at any regular meeting by a two-thirds ( $\frac{2}{3}$ ) vote of the Academy, provided that after the year of 1894 not more than five (5) Honorary Fellows shall be elected at any annual meeting.

#### PENALTIES.

4.—Upon a sufficient showing that a Fellow has been wilfully guilty of gross violation of the laws governing the Academy, or any form of professional misconduct, the Executive Board may recommend that his resignation be requested, or move his suspension or expulsion. A majority vote of the Fellows present, at an Executive Session, being necessary to fix the penalty.

#### OFFICERS.

5.—The officers of the Academy shall consist of: A President; two Vice-Presidents; a Secretary; a Treasurer; an Editor; an Executive Board of seven (7) including the President, the Secretary and the Treasurer, who shall be *ex-officio* members thereof.

#### ELECTIONS.

6.—Applications for Fellowship shall be made in writing to the Executive Board signed by three (3) Active Fellows who are personally acquainted with the candidate. Upon a favorable report by the Executive Board a ballot shall be ordered, when if not more than three (3) negative votes appear, the candidate shall be declared elected.

The officers of the Academy shall be elected on the last day of each annual session by ballot; a majority vote of the Fellows present being necessary to a choice.

#### MEETINGS.

7.—The annual session of the Academy shall be held at such time and place as shall be designated by a majority vote at the previous annual session; and each session shall continue for three (3) days, unless otherwise ordered by the Academy.

An executive session for the transaction of business shall be held on the morning of the first day of each session, none but active Fellows of the Academy being present.

#### BY-LAWS AND RULES OF ORDER.

1.—The President shall preside at all regular meetings of the Academy, sign all official documents, and perform the ordinary duties appertaining to his office. In his absence one of the Vice-Presidents shall occupy the chair in the order of seniority; or if both of them are absent, by a Fellow elected by the Academy.

The Secretary shall keep a correct record of the proceedings of the Academy, give notice of the time and place of all meetings, receive the signatures of Fellows, sign official

documents and take charge of all property of the Academy not otherwise provided for.

The Treasurer shall receive all money paid into the Academy and disburse it upon the authorized order of the President and Secretary. He shall make a full report, and his accounts shall be audited by a select committee appointed for that purpose at each annual session.

The duties of the Editor shall be those ordinarily pertaining to such an office. He shall edit all the papers and discussions, and see that they are published as directed by the Academy. He shall act as a member of the Publication Committee, consult with said Committee regarding the publication or exclusion of any paper or discussion submitted to him for publication, and assist in securing papers for each annual meeting and the proper arrangement of the same on the program, and such other duties as may be assigned him by the Committee on Publication.

#### EXECUTIVE BOARD.

2.—At the annual session of the Academy in 1894, four Fellows of the Executive Board shall be elected; one to serve one year, one to serve two years, one to serve three years and one to serve four years; at each annual session thereafter one member of the Executive Board shall be elected to serve four years. The functions of the Executive Board shall be both judicial and executive; it shall have the general supervision of the affairs of the Academy; it shall recommend candidates for membership in the Academy, and it alone shall have the power of moving their expulsion or suspension for any alleged offense against the Constitution or By-Laws. It shall act as a Committee on Credentials, hold any necessary meetings in the interval between sessions, and its action shall be deemed the action of the Academy unless reversed by that body.

#### COMMITTEES.

3.—Committee on Transportation. At each annual session the President shall appoint a Committee on Transportation consisting of three (3) Fellows. It shall be the duty of this Committee, as far as possible, to arrange with the various railway companies for the transportation of the Fellows of the Academy to and from the annual session. They shall cause the publication of a list of railways granting transportation, and other necessary information.

Committee on Publication. The President, Secretary, Treasurer and Editor shall constitute a Committee on Publication to which shall be referred all papers, reports and other matter suitable for publication by the Academy.

Committee of Arrangements. A Committee of Arrangements, consisting of three (3) Fellows, shall be appointed by the President at each annual session, the Chairman of which shall reside in the place where the next annual session is to be held. This Committee shall confer with the Committee on Publication in the preparation of the program for the next annual session, a copy of which shall always be sent to each Fellow at least one month before the opening of the session; and shall make all necessary preparation for the meeting of the Academy.

#### SCIENTIFIC WORK.

4.—The scientific work of the Academy shall be divided into: 1, surgical; 2, medico-legal; 3, sanitary.

All papers and reports of discussion shall become the exclusive property of the Academy, subject to such disposition as shall be ordered by the Committee on Publication.

#### MEMBERSHIP FEE.

5.—The admission fee shall be five dollars (\$5), to be paid when the application is made. Should the applicant fail of election this fee shall be returned to him.

#### DUES.

6.—The annual dues shall be five dollars (\$5) payable on or before the last day of the annual meeting. Neglect or

failure on the part of any Fellow to pay his dues shall forfeit his right to vote or receive the perquisites of the Academy, until his dues are paid, and the failure to pay his dues after the annual meeting shall forfeit his Fellowship.

#### QUORUM.

7.—Any number of Fellows present at the appointed time of the annual session shall constitute a quorum for the transaction of ordinary business, but for the election or expulsion of Fellows, or for altering the Constitution and By-Laws, twenty-five (25) Fellows shall be required to form a quorum.

#### ORDER OF BUSINESS.

- 8.—1. Call to order.
2. Addresses or other special exercises as prepared by the Committee of Arrangements.
3. Reading minutes of previous meeting.
4. Report of officers and committees.
5. Miscellaneous business.
6. Announcements.
7. Reading reports of cases and exhibitions of patients, specimens, apparatus, etc.
8. Reading and discussion of papers.
9. Unfinished business.
10. Election.

#### RULES.

9.—Roberts' Rules of Order shall govern the deliberations of the Academy.

#### AMENDMENTS.

10.—Proposed amendments to the Constitution and By-Laws must be offered in writing, at a regular session, and shall not be acted upon until the next ensuing annual session, when a two-thirds ( $\frac{2}{3}$ ) vote of the Fellows present shall be necessary to adopt.

On motion of DR. R. HARVEY REED, the report was considered, section by section.

On motion of DR. WEBB J. KELLY, the amended Constitution and By-Laws were adopted as a whole.

On motion of DR. R. S. HARNDEN, the appointing of a Committee on Nominations was dispensed with.

DR. R. HARVEY REED reported that an option had been offered the Academy from the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, whereby said JOURNAL would furnish the Academy a department, and would permit of the Academy's appointing its own Editor; and that he would furnish to the Academy a bound volume of the transactions of the Academy, bound in cloth, price not to exceed \$1 per volume.

On motion of DR. R. HARVEY REED, the Academy accepted the proposition from the Editor of the JOURNAL, and the chair appointed a Committee, consisting of Dr. R. Harvey Reed, Columbus, Ohio; Dr. John E. Owens, Chicago, Ill.; and Dr. C. K. Cole, Helena, Mont., with instructions to close said contract and the committee was further instructed to make a contract with the Editor of the JOURNAL for three hundred (300) bound volumes of the Transactions, the price not to exceed one dollar (\$1) per volume.

On motion of DR. C. D. EVANS, the election of officers was made the special order of business at 2 P.M. Saturday.

On motion of DR. F. H. CALDWELL, the banquet was abandoned.

Adjourned until Saturday morning, 9 A.M.

(To be continued.)

### Louisville Academy of Medicine.

The second regular meeting of this society was held in its rooms in the Fonda Building, Monday evening, January 7, its President, DR. T. L. McDERMOTT in the chair. The subject occupying the attention of the members was a continued discussion of Dr. Bailey's remarks at the last meeting: "Shall

the antiseptic vaginal douche be a routine procedure in obstetrical practice?"

DR. W. H. WATHEN stated that when a woman is healthy and in labor her vagina is practically aseptic; the vaginal secretions have a cleansing effect, and if there is any septic material in the vagina or uterus it must have been conveyed there by the attendant. If the douche is adopted as a routine practice it will cause twenty-five cases of sepsis where it will prevent one. Since the general adoption of this practice it has killed ten where it has saved the life of one. He asserted that he was positively opposed to the douche as a routine practice, and that it should never be used save where sepsis is suspected, and then not only as a vaginal but also as an intra-uterine douche, since if infection is in the vagina it is also in the uterus, because of the intimate relationship of the parts and the likelihood of absorption by lymphatics. Puerperal sepsis is nearly always exogenous.

DR. H. A. COTTELL stated that when the aseptic and antiseptic midwifery craze struck the country he reviewed an article in which the stand was taken that the antiseptic precautions should begin as early as the sixth or seventh month, and it called forth a comment from him. Should not the spermatozoid be made aseptic before being allowed to go on its way? He took the ground that labor is a physiologic process, and not pathological, and when this factor enters into it then is the time to use antiseptic precautions. The woman in the parturient condition is in a physiological condition not a surgical. Nature protects the case by making a glazed surface of granulations over these rents and tears which occur in all cases, and the germs are not absorbed, but pass over them; give a douche, however, the granulations are broken up, and absorption occurs. He does not believe in auto-infection, and believes this new theory of sepsis being due to the bacterium coli communi, simply an excuse, that it is not probable that these bacteria enter the vagina from the anus, and it is impossible for them to penetrate the tissues. In catheterizing lying-in women, he could not help but say a word of warning against the introduction of the catheter by the sense of touch. Expose the patient, cleanse the parts about the meatus, then introduce a clean catheter.

DR. J. B. BULLITT.—Nowadays there are few advocates of the douche following labor, except when there is sepsis, then an intra-uterine douche, preceded by a curettement and followed by packing for drainage. In Germany, very radical measures are used, and the mortality is much reduced. If a douche be given, it must never be given save by the doctor or trained nurse. The whole question could be settled by discouraging vaginal examinations. Keep hand out of vagina but follow the progress of labor by external palpation.

DR. HENRY E. TULEY stated that in order to refute one or two statements of Dr. Wathen's, he would relate his experience as resident at one of the large maternity hospitals of the East. Sloane Maternity Hospital, New York, where vaginal douches of bichlorid, 1 to 5,000, were a routine practice. Immediately after admission, the patient was given a full bath and a vaginal douche, if not in labor. When labor began, she was given a douche, and an enema, followed by a douche directly after labor. Then many examinations were made, by the students as well as the nurses, and of the 222 cases delivered during his three months residence there were only 3 cases who had temperature which could not be explained as being due to other causes than sepsis.

DR. TULEY exhibited before the Academy a douche nozzle, the same as used at Sloane; it is made of glass, smaller than a Chamberlain tube, with a small curve at the end, and

near the other end a bulb, blown in the tube, which serves as an index as to where the tip of the tube is, it being on the same side with it. Though so successful in hospital practice with the vaginal douche, both before and after labor, Dr. Tuley stated that in his opinion the douche in private practice was impracticable.

DR. FRANK stated that in his opinion the douche in private practice as a routine, was inadvisable. Labor is a normal condition, and may become surgical. In obstetrical surgery as version, the douche is advisable. The secretion of the vagina and the amniotic fluid tend to rid the vagina of any bacteria present. If bacteria are resident in vagina they must be gotten rid of, but this can be accomplished, not by the douche alone, but only by scrubbing the same as would be done before any operative work upon the uterus or vagina. He spoke of the method of ballooning the vagina, which he had been unable to find mentioned anywhere, in giving the douche, which is accomplished by introducing the fingers with the tube, which acts as a plug, the water accumulates and distends the vagina.

DR. BAILEY, in closing the discussion, stated his appreciation for the liberal remarks made. He said that the secretion of the vagina takes care of most of the bacteria present, neutralizing their effect, but if they are present in the uterus he advised a douche, as the uterus secretion cannot do the same thing. He called attention to some remarks made in his paper, in regard to a vaginal douche given before labor, preventing the blindness which is so common in children. He disagreed with Dr. Frank as to the ballooning the vagina of a lying-in woman by distending it with water, owing to the possibility of forcing some of the dislodged septic materia through the patulous or into perhaps an aseptic uterus.

At the conclusion of the discussion, the Academy was entertained by the address of its President, Dr. T. L. McDermott.—(See page 109.)

## BOOK NOTICES.

**Blood Serum Therapy and Antitoxins.** By GEO. E. KRIEGER, M.D. With illustrations. CL., pp. 69. Chicago: C. H. Colegrove & Company. 1895.

This timely monograph is an excellent *resume* of the existing state of knowledge and current literature on this subject. The contents are as follows:

Chapter I, Blood Serum Therapy; II, Toxins and Toxalbumins; III, Tetanus; IV, Diphtheria. The author has produced a well-written book; there are a few errors of proof reading and some of orthography, such as "chaolin" instead of kaolin, page 18; "paralize" instead of paralyze, page 26, and some sentences which betray the German idiom, but these are minor defects and do not materially detract from the great merit of the work. We hope to chronicle the fact that this little book has passed to its second edition, and as there is great need of the special information contained in it, we feel sure that the hope will be realized at an early day.

**Myxœdema, Cretinism and the Goitres with some of Their Relations.** By EDWARD T. BLAKE, M.D., M.R.C.S. Paper, pp. 89. Bristol: John Wright & Co. 1894.

The author in this brochure seeks to establish the septic or infectious nature of the disease and the propositions he endeavors to establish are: 1, that Graves' disease in women is an autotoxis, most frequently caused by absorption of purulent products; that process being *aided*, rather than *induced*, by the toxins of terror and shock; 2, the same products lead to the production of rheumatism in males, by acting in the same locality, viz., the medulla oblongata; 3, if these products abolish the functions of the thyroid, we

may get myxœdema; 4, if these products invade the cortex, in large quantity and abruptly, we get a psychosis, as for example, mania or some neurosis such as epilepsy; 5, if the invasion be more gradual and the poisons more diluted, we get chorea.

The brochure is well written and extremely interesting.

## NECROLOGY.

DR. BENJAMIN FREEMAN FESSENDEN, the subject of this sketch, was born in Plymouth, N. C., Sept. 16, 1818. His father came from Massachusetts. Early left an orphan, he was brought up by a conscientious guardian, who took excellent care of his early education.

Having completed his preparatory studies, he entered the University of Pennsylvania, and graduated with honor in 1842. His thesis on graduating was "Unguentum Hydrargyri Nitratis vel Unguentum Citrini." Under the head of "Citrine Ointment," in Wood & Bache's "Dispensatory," Dr. Fessenden's thesis is mentioned and his methods approved.

The Doctor married early, and practiced his profession in his native place until the War of the Rebellion broke out. He was at once made Surgeon-General in the Confederate Army and was Medical Director of the State of North Carolina, all through the war.

After the war, in 1865, he moved to Brooklyn. Then began an acquaintance between the Doctor and the writer of this sketch that ripened into the firmest friendship, broken only by his death. Dr. Fessenden was a man not easy to become acquainted with; but when once well known he was highly appreciated for his sturdy virtues and the excellencies of mind and heart which he possessed. Living opposite me for nineteen years, I was in his house, or he in mine, almost every day. I have been with him by the bedsides of his sick and dying loved ones, and he has been with me on similar occasions. His courage, cheerfulness, sweet and manly resignation to the Master's will have compelled my perfect admiration. His words and acts of solace and comfort to me have touched my heart and made me love him as a brother.

Dr. Fessenden was sometimes brusque in manner, never fond of show, and all kindly in heart. He was a great student of literature and could repeat many portions of Shakespeare; nearly, if not all, of Pope's essays, especially the "Essay on Man," and would often amuse and delight his friends by his excellent recitals of some of them.

In the sick chamber he required strict obedience, and rewarded it with kind, constant and skillful attention. He made it a point to be kind and helpful to the younger members of the profession; and so honest was he that, as he often told me, he early made it a rule of his life—from which he never swerved—never to take a patient from any other doctor, if it were possible not to do so; but always to have some good word to say, or some reason to give, why the patient should continue with the doctor he was then employing. This reputation he enjoyed to the last.

He was positive in character, and for this reason his friendships were ever faithful and deeply rooted, and his dislikes equally pronounced. Many men, women and children learned to love him, and many have told me how much they miss his pleasant smile, his kind, cordial, gentle, yet decisive advice.

Dr. Fessenden was one of the first members of our Association and he took a great interest in it. He was, I believe, the first to be taken from us by death. In years, he was one of the oldest physicians in Brooklyn.

For more than a year he has occasionally complained of vertigo, which he believed to be due to the inactivity of his liver and kidneys. This, however, generally readily yielded to treatment and passed off. It was not until early in July last, when the Doctor had an attack that seemed to him like a light stroke of apoplexy, that he felt the necessity of calling in a physician. When I saw him first, he seemed to appreciate his condition; but was not at all alarmed and professed himself ready. His disease was fatty degeneration

of the kidneys, and in spite of the best medical care and the most careful and loving nursing, he sank into a deep coma, and on the 27th of July quietly and peacefully passed away, to join his loved ones in the land where sorrow and sickness and parting never come.

He has left a clean clear record, and many, very many, sorrowing friends, who will never forget him. We are among these.

"His fight is fought, his battle done;  
The victory of his life is won;  
The peacefulness of his rest begun."

Published in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION by request of the Kings County N. Y. Medical Association.

NATHAN CARTWELL, M.D., died in Tustin, Orange County, Cal., Jan. 3, 1895, suddenly, of neuralgia of the heart. He was born in Nelson County, Ky., and went to Louisville when a boy. Wrote in the clerk's office under Worden Pope and was a student in the Medical College. He located in Union County, Ky., where he lived many years, engaging successfully in the mercantile business and later in banking. In 1883 he removed to Waco, Texas, and entered into the banking business with a former partner, under the old name of Cartwell, Higginson & Co., but the climate not suiting his always delicate health, in January, 1887, he sought Southern California, where his last years were peacefully passed on an orange ranch. In January, 1869, he married Llewellyn, eldest of Judge Huston of Morganfield, who with seven children mourns his loss. Dr. Cartwell was a man of unquestioned integrity, and a devoted member of the Episcopal Church.

D. D. BELKNAP, M.D., of Whitewater, Wis., January 15, aged 75.—Frank M. Trude, M.D., of Chicago, January 14, aged 26.—Stephen Roof, M.D., of New York, January 10.—Myron Leslie Baxter, M.D., at Derby Line, Vt., January 8, aged 55 years. He was a brother of the late Surgeon-General Baxter of the Army.

## SOCIETY NEWS.

**Burlington County (N.J.) Medical Society.**—The Burlington County Medical Society held its annual meeting at Mount Holly January 15. The following officers were elected: President, F. G. Stroud; Vice-President, J. H. Pugh; Secretary, A. W. Taylor.

**Oakland County (Mich.) Medical Society.**—The Oakland County Medical Society held a regular meeting at Pontiac January 9.

**Montgomery County (Pa.) Medical Society.**—The Montgomery County Medical Society held its annual meeting at Morristown January 9. The following officers were elected for the ensuing year: President, J. L. Weaver; Vice-Presidents, J. R. Care, of Worcester, and S. R. Hunsberger, of Skippack; Recording Secretary, H. H. Whitcomb; Corresponding Secretary, J. K. Weaver; Treasurer, S. N. Wiley.

**American Association of Obstetricians and Gynecologists.**—This Association will meet in Chicago next September.

**Medico-Pathological Society.**—The annual meeting of the Medico-Pathological Society of York City, Pa., was held January 10. The following officers were elected: President, I. H. Betz; Vice-Presidents, W. H. Minnich and G. E. Holtzopple; Secretary, S. K. Pfaltzgraff; Treasurer, J. F. Klinedinst. The annual banquet of this Society will be held February 14.

**Will County (Ill.) Medical Society.**—The annual meeting of the Will County Medical Society was held January 10. The following officers were elected: President, Wm. Richards; Vice-President, R. G. Rulien; Secretary and Treasurer, Wm. Dougall.

**Newport (R. I.) Medical Society.**—The Newport Medical

Society held its annual meeting January 16. Honorary President, N. H. Storer; President, Francis H. Rankin; Vice-President, C. F. Barker; Secretary, Mary E. Baldwin.

**Chicago Ophthalmological and Otological Society.**—Regular meeting held Dec. 11, 1894. Dr. Hotz in the chair. There were twenty-six members and visitors in attendance.

On motion, the reading of the minutes of the last meeting was omitted.

DRS. MARY HOLLISTER, Paul Guilford and F. E. Gavin were elected members.

The application of Dr. W. E. Gamble was read and referred to the Committee on Membership.

DR. GRADLE showed a specimen of tumor of choroid, presumably sarcoma, preserved in formalin. The colors and transparency were life like. He also referred to an article by Beer, in *Archiv für Physiologie*, on the accommodation of fishes' eyes. The rest of the evening was occupied by Dr. Meyer of Kankakee, with an essay on "Cranial Nerves."

On motion the Society adjourned.

103 State Street.

C. P. PINCKARD, Secretary.

## SELECTIONS.

**A New Constituent of the Atmosphere.**—The proportional parts of the essential constituents of the atmosphere, oxygen and nitrogen, were determined with much accuracy more than one hundred years ago. For an almost equal length of time it has been thought that these gases with three others—carbonic acid, ammonia, and water vapor, which occur in very small quantities, were the only other all-persistent components of the atmosphere, that is, components not due to local causes. It was, accordingly to be expected that the announcement of a new constituent of the atmosphere would be received with surprise and interest. This announcement was made at the last meeting of the British Association for the Advancement of Science, in August of this year. The suggestion of a new constituent came to Lord Rayleigh in 1893, while determining the densities of the principal gases. In these investigations he discovered that the nitrogen obtained by the decomposition of ammonia was lighter than nitrogen obtained from the air. He at first thought that this might be due to the existence of an allotropic form of nitrogen, similar to the modified form of oxygen known as ozone. By April, 1894, Lord Rayleigh had determined the density of nitrogen obtained from ammonia, from nitrous and nitric oxides, and from ammonium nitrite—and it was found to be the same in each case, but different from the density of nitrogen obtained from the atmosphere. After this result was reached, Lord Rayleigh satisfied himself that the difference could not be due to the presence of any known gas likely to be present. He then, in conjunction with Professor Ramsay, removed both the oxygen and nitrogen from a certain volume of air and found that a substance was left that was neither oxygen nor nitrogen, as was proven by its spectrum; the oxygen and nitrogen were removed from air by different processes, and in each case the new substance was left. Since the announcement of the discovery, no investigations tending to throw light on the nature and properties of the new substance have been published, and it is not known whether it is an element or a compound. According to the discoverers it constitutes about 1 per cent of the atmosphere. Professor Dewar had previously noticed that liquefied oxygen and nitrogen gave a clear liquid, while the liquefied atmosphere was turbid, and it has been suggested that this new constituent of the atmosphere may have caused the turbidity; but Professor Dewar says that the substance producing the turbidity can not amount to 1 per cent. It may be confidently assumed that if there has been no mistake, the discovery will soon be verified and the properties of the new substance determined.—PROF. S. E. TILLMAN, U. S. M. A., in *Cosmopolitan*, January, 1895.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, JANUARY 26, 1895.

ADVICE TO YOUNG OCULISTS.

Since the extraction of cataracts without iridectomy has been reintroduced into ophthalmic practice, there has scarcely ever been a meeting of oculists at which the question of cataract operation with or without iridectomy has not been debated. But as usual in medical discussions, the main question is generally lost sight of and each speaker dwells upon some pet hobby—some little modification or so-called improvement in the operative technique, which he insists is very essential to the success of the operation; and the longer the question is debated the farther the opinions seem to drift away from each other. Upon the experienced oculist these discussions make no impression; as HANSEN GRUT said at the Ophthalmological Congress at Edinburgh, they only show what was known before, that cataracts can be successfully extracted in various ways. But the young oculist who hears or reads these conflicting views, is in danger of losing all confidence in himself and of feeling entirely at sea as to the proper method of operating.

For these young oculists, DR. HERMANN PAGENSTECHE, of Wiesbaden, has recently published in the *Klinische Monatsblätter für Augenheilkunde* a short paper full of good, sensible and practical advice: "The young oculist should never try experiments, but adhere to those indications and to that operative method which experience has shown us to be the easiest in execution and the safest in restoring the sight. And this method is the extraction with iridectomy, because it can be employed in all cases, while the simple extraction is limited to certain kinds of cataracts whose proper selection is very difficult, even after long experience.

"We can operate without iridectomy in all cases in which we can with certainty expect that we take no chances of a subsequent protrusion of the iris. Unfortunately, this is not always possible, and it is this weak point which will frustrate all efforts of making the extraction without iridectomy, the operation for all uncomplicated senile cataracts. Even the most expert operator is never able before the operation, to tell with absolute certainty that he will operate on this eye without iridectomy and without risking a prolapse of the iris. This fact alone is to me sufficient to advise every young oculist not to operate without iridectomy; for to excise *lege artis*, the iris after the removal of the lens requires a far greater dexterity than the iridectomy before the extraction." DR. PAGENSTECHE concedes the operation without iridectomy has some advantages; it preserves the natural round pupil, and usually the eyes show less irritation during the healing process. But it also has its serious drawbacks; cortical remains can not be thoroughly removed; hence posterior synechiæ and secondary cataracts are more frequent than after the extraction with iridectomy; but the chief drawbacks are the incarceration and prolapse of the iris, of which even the most expert operators report 8 to 10 and more per cent.; these accidents always retard the healing process, produce a hideous distortion of the pupil, and sometimes have caused the loss of the eye by suppuration or irido-cyclitis. "This is a sad experience and too dear a price for even the greatest series of nice round pupils."

But if such disastrous results occur in the practice of a surgeon having an unusually large experience, so much more reason for the beginner, in the interest of his patients and for his own good, not to practice the operation without iridectomy. He shall first acquire experience and the greatest manual dexterity with an operative procedure by which he can operate upon *all* cataracts (and this is the operation *with* iridectomy); then, he will, by-and-by, find out for himself when and how much he may with safety depart from his accustomed practice.

MEDICAL EDUCATION.

The present is a period of evolution in methods of medical education. Colleges have nothing to lose and much to gain in enforcing honest high grade work. Up to a period of the last few years the profession as a whole, was notably indifferent as to the character of work being carried on in the various colleges although societies passed the usual perennial resolutions. The number of truly high grade institutions could be counted upon the fingers of one hand. They were not supported by the profession with that unanimity that their efforts merited; indeed, in a few instances these schools were for years upon the verge of starvation.

Through stress of circumstances and with the con-

currence of the indifferent preceptor, the student selected that college wherein he could secure his degree with the greatest ease. The result has been to flood the country with a profession, a large number of whom are not as well educated as the average man in other walks of life. In consequence the medical profession as a whole has suffered. To-day, however, the situation is quite changed. As the result of an aroused professional and public sentiment, we have in sixteen States in this country, medical laws that fail to recognize the diploma as an equivalent evidence to entitle the holders to practice medicine. These persons are required to prove their fitness to practice by undergoing a personal examination upon all the branches included in the field of medicine. The work of these boards can not be hidden. A series of statistics published, covering over two thousand examinations indicate that one-fourth of all applicants fail to pass their examinations. In an additional paper about to be published a similar condition of affairs will be found to exist, thus bringing the statistics down to January of the present year. Like the first paper it will be found that in making a comparison of the proportion of alumni, successful before the different boards, that those schools exacting good work rarely fail, upwards of 95 per cent. of all applicants being successful, while the graduates of the schools of the second grade suffer in alarming proportions, viewing the question from the standpoint of the disappointed student. In analyzing the work of these boards as applied to the medical colleges of the country but one conclusion can be inferred: It is, that the proportion of graduates of the individual colleges will accurately and impartially indicate the character of medical instruction being afforded by each school at the time of conferring the degree.

The influences that have been at work in bringing about the wide medical legislation of this country being so recent are familiar to all; suffice it to say that it was accomplished without the assistance or even the coöperation of the faculties of the medical colleges of the country; with a few exceptions, where the faculties of some of the high grade schools joined with the promoters of the proposed legislation.

It is our opinion that notwithstanding the far reaching influence of the medical press, and the support of the various medical societies of the country, medical legislation alone caused the healthy reform. It is also apparent that the enforcement of efficient medical legislation in a few States will do more in destroying the dangerous work of the low grade college than all other factors combined.

The history of reform in methods of medical education in this country is about as follows: The Constitution of our ASSOCIATION provided for a standing committee on medical education, and the ASSOCIATION

took the initiative, and as far back as in 1847 the faculty of the University of Pennsylvania made an ineffectual effort to bring about needed reforms in methods of teaching. After a prolonged trial it was abandoned. In later years, Bellevue Hospital Medical College suffered a similar experience; the first Association of American Medical Colleges was disrupted through the action of the representatives of a few of the low grade schools and a similar effort was made to disrupt the work of the present college association but fortunately without success. Up to the period of establishing efficient medical legislation, about five years ago, the low grade college seemed to thrive. About this time those colleges that had adopted the change from the two- to the three-year course observed an increased attendance instead of the falling off that was really expected by the deans of each school. It was at this time that the present Association of American Medical Colleges was organized, and aided by the efficient work and influence of the various State boards was the precipitating influence in bringing about the adoption of the three-term requirement by the fifty-four schools that subscribed to its by-laws the year of its organization. The change from the three to the four years course is being accomplished much in the same way. It is the experience of the schools that anticipated this great reform and are now working under the four year curricula, that they have an increased attendance. As affecting the colleges themselves there is but one interpretation, looking at this question from the college standpoint: It is that the time has arrived when the student seeks the doors of that institution that affords the best facilities for instruction. Our boys do not care to be limited in their practice to those States not blessed with laws regulating medical practice, but upon the contrary recognize that the day of the low grade medical college is on the wane, and that disgrace faces the work of all such institutions, and will continue to do so, so long as we have efficient medical practice laws.

The action of the Association of American Medical Colleges in adopting the four year curriculum at San Francisco last year will prove to have been the precipitating factor in stepping from the three to the four year's requirement by the colleges of the country. We hear nothing but good news in this direction. The provisions of the four year's curricula goes into operation with all new matriculates beginning with this present calendar year, who are members of the College Association or of the "Homeopathic" College Association. The resolutions adopted by the AMERICAN MEDICAL ASSOCIATION on this point become operative with all matriculates of the present year; and in the future if they ever hope to become members of this body. It is reliably re-

ported that at the present writing, forty-two medical colleges, members of the College Association have indicated their intentions favorably on the new regulations of this body. Unless all signs fail, about every college situated in the Northern States will require of the 1895 entering class, attendance upon at least four courses of medical lectures, in different years, before conferring the degree of M.D. Reports from the other medical colleges are not so favorable. We are of opinion, however, that the profession of the other States will not long tolerate lagging upon a question of this character. The colleges working under the four years' requirement at the present time have an increased attendance in their freshman class. They will open their doors the coming fall with still further increase of attendance, while those colleges which fail to grasp the situation and adapt themselves thereto, will be placed in an embarrassing position, as well as the extreme probability of having for their class of new matriculates an inferior quality of men. The time is near at hand when the faculties will be looking into the work of the coming session, and the question of the adoption of the new standard will be the all-important question of policy, if not already decided upon. In view of the emphatic resolutions adopted at several sessions of the ASSOCIATION under whose auspices this JOURNAL is published, we are reminded that this is an opportune time to discuss this subject. There is no known excuse why the colleges should not at once unanimously adopt the four-year requirements. If any exist, we will gladly give space for their citation in these columns; on the contrary, we believe the arguments in favor of the proposed change to be many and imperative, and until the action shall have been rescinded, we shall advocate that policy, in impressing upon the representatives of these schools the necessities of continued reform in medical education. With the adoption of the four years course we will hear less upon this subject from Europe, and we will be able in the near future to point to a profession whose general information is upon a par with that of any European nation. We shall look for the receipt of the usual grist of 1895 announcements with additional interest.

#### THE NAVAL RE-ORGANIZATION BILL.

The young officers of the line of the Navy have concocted a new scheme for speedy promotion, which, if worked through Congress as at present framed, will do the Medical Corps great harm.

The new bill is neither in the interest of economy or efficient service, and as already intimated, was apparently born of a desire to secure promotion without regard to the great injustice inflicted upon the staff, or to the older officers of the line who are unfavorably affected by the bill.

One section alone of this iniquitous bill shows its true nature quite clearly. It is that which provides for ten additional rear admirals. We now have six, to command the 8,500 enlisted men of the Navy, when the Army of 25,000 enlisted men are satisfied with three major generals, (having the same rank as rear admiral). It is well known there are only five stations which require rear admirals; if this bill should pass there will be eleven rear admirals on shore to help increase the deficiency in the treasury. There are now 719 line officers on the active naval list of whom more than half are on shore, if we leave out of the count those on coast survey duty, and count them as at sea.

The reserve list created by Section 14 of this bill puts out of active service some of the ablest men in the Navy, and operates to reduce the pay of the Medical, Pay and Engineer Corps, simply that some young line carpet knights below the rank of lieutenant-commander may be promoted.

"Why," asks the correspondent of the *Brooklyn Eagle*, "should a doctor's pay be diminished because of any change in the line? His value does not depend upon the line. The market value of a doctor does not depend upon the supply of ensigns. He comes from civil life, and his pay should be fixed at what good men of his profession are worth. What has a paymaster's pay to do with the line? His bond of \$25,000 and his responsibilities in handling thousands of dollars, his business instincts and training are what should be considered. These men have educated themselves, and no officer of the staff can reach the ultimate high pay of the line or hope for the remarkable promotion provided for the line by this bill. Any one can see who reads this bill that it is a line measure and a measure for only a part of the line. It degrades the staff and makes it the servants only of this part of the line. It makes a plaything of the Navy for their benefit—a costly plaything. It creates in its provisions for promotion what might be called the lottery scheme for the line of the Navy. The senior lieutenants, lieutenant commanders, commanders and captains either draw prizes or are turned down. Commanders who feel quite certain of selection say that they fully expect to be rear admirals within two years of the passage of this act, many lieutenants will be commanders and ensigns lieutenants. This bill benefits those in the line who profit by the reserve list. All other officers are tributary to them, and either lose all prospect of a better future or contribute directly to the support of those fortunate enough to be rapidly advanced. A minority desire ultimately to profit tremendously. It is the active aggressive minority which is endeavoring to push to the wall all who are in the way. This lottery scheme of the Navy has by its very proposal already done much to injure the morale of the service. The people of this enlightened country will never understand this mixture of extravagance and injustice.

"Another feature of this reserve list is that it is perpetuated. It does not die with the ninety-five men blacklisted. Section 12 provides that there shall be each year sixteen promotions in the list of sea-going officers to the grade of commander, and twenty promotions to the grade of lieutenant commander, and that when this number does not occur naturally it is to be created by forcing a sufficient number of officers from these grades on the reserve list. This blacklisting and scramble is to go on indefinitely, and for every man so degraded another enters to keep the line corps up to 720. No such firebrand as this bill has been cast at the Navy since 1855. It is a mistake to think that this bill is wanted by the service at large. It is opposed by 90 per cent. of the line officers of and above the grade of lieutenant commander and by every member of the Medical, Pay and Engineer Corps. Along with the desire to kill the ambition of the best part of the line, there is woven in this bill the intention to hold down and oppress the staff corps. It treats the Medical, Pay and Engineer Corps, as if designed expressly for the purpose of destroying their efficiency, humiliating their members and making them the servants of the line

branch rather than of their country. Such a bill as this is devoid of every sign of justice and fair play. The Medical, Pay and Engineer Corps are absolutely essential to the efficiency of the naval service."

It seems impossible that such a wholesale plunder of the public treasury would or could pass Congress. We read of the forty admirals now on the retired list, and we have read of the forty thieves. We sincerely trust that the zeal for promotion of the young midshipmen, will not lead to the general belief that the terms may become synonymous.

#### "SUNDOWN DOCTORS AND EVENING COLLEGES."

In our Washington news of January 5, note was made of an order of the Commissioner of Pensions preventing clerks in the Bureau, who are physicians, from practicing medicine after office hours. In this branch of the government service, as well as in others, there are a number of graduated physicians who attend patients after office hours and are known as "Sundown Doctors." This item has been recurring frequently to our mind since it was published, and always coupled with the idea that if there were no evening colleges in Washington, D. C., there would be fewer "sundown" doctors in that city. A medical man may find practice unremunerative or uncongenial to him and may accept a place in the government service, particularly in the Bureau of Pensions, the Record and Pension Division of the War Department or the Office of the Surgeon-General of the Army, Navy or Marine-Hospital Service, where his medical knowledge would increase his clerical efficiency and status. There would, therefore, always be found in these offices a certain number of medical graduates, most of whom, however, would be satisfied with their official position.

The Federal Capital is almost the only city in the United States where are to be found medical colleges with a lecture program which begins no earlier in the day than 5:30 P.M. The object of these late lectures is evidently to gather in from the Departments those ambitious young men who feel that they were made for something better than the routinism of departmental office work. Medical study and, with due respect to the faculties, medical teaching, to be efficient, should put to use all the mental energy of the individual. Night classes, therefore, can not be productive of as good results as day classes. The clerk, who has studied and graduated at a night school hesitates to cut adrift from his clerkship to undertake the responsibilities of life in his new profession and he practices, as he studied, after sundown. The medical colleges of Washington point with pride to their record and their lists of graduates to show their status; but since they do so well now, it is evident that they would do better and stand on a much higher plane if all the brightness of the day instead of only the dullness of its fag end

were devoted to the work of education. One night college is enough for the needs of those who can not afford to give the day to study. The other colleges of the Federal City should call for the best energies of their students and support their curriculum with the best energies of their teachers. With the four years' course which is now required, with their able professors and well-equipped laboratories, and all the facilities which Washington offers for medical study there is wanted only day classes to make that city an educational center of national importance.

#### THE WEATHER BUREAU AND SANITARY CLIMATOLOGY.

Last year the Chief of the Weather Bureau sent out a letter to sanitarians and others, inviting opinions on the best means of making the weather service of the United States of benefit to sanitary science. The Editor of this JOURNAL among others sent a rather lengthy letter dated Jan. 20, 1894, giving suggestions in detail. We are therefore greatly pleased to see that the Bureau has moved in the matter, and we feel sure that its action will be sustained by the medical profession generally. The great influence of climate in the etiology and as well in the therapeutics of disease, has been so little studied, that it is very gratifying to see that the Agricultural Department is prepared to start the movement.

The following circulars are self-explanatory:

##### Circular No. 3. Sanitary Climatology.

{ U. S. DEPARTMENT OF AGRICULTURE,  
WEATHER BUREAU.  
WASHINGTON, D. C., Jan. 2, 1895.

*To the Editor:*—At the instance of the Honorable the Secretary of Agriculture, the Weather Bureau will extend the scope of its work, as set forth in the accompanying circular.

As there are doubtless many persons who may be interested in the proposed investigation and willing to coöperate and whose names are not known to the Bureau, I would be pleased if you would give notice of this investigation in the columns of your publication.

Very respectfully,

MARK W. HARRINGTON, Chief of Bureau.

##### Circular No. 1. Sanitary Climatology.

{ U. S. DEPARTMENT OF AGRICULTURE,  
WEATHER BUREAU.  
WASHINGTON, D. C., Jan. 2, 1895.

The interest manifested by every class of people in the subject of climate and its influence on health and disease has determined the Honorable the Secretary of Agriculture, through the medium of the Weather Bureau, to undertake the systematic investigation of the subject.

It is hoped to make the proposed investigation of interest and value to all, but especially to the medical and sanitary professions, and to the large number of persons who seek, by visitation of health resorts and change of climate, either to restore health or prolong lives incurably affected or to ward off threatened disease.

The study of the climates of the country in con-

nection with the indigenous diseases should be of material service to every community in showing to what degree local climatic peculiarities may favor or combat the development of the different diseases, and by suggesting, in many instances, supplementary sanitary precautions; also by indicating to what part of the country invalids and health seekers may be sent to find climatic surroundings best adapted to the alleviation or cure of their particular cases.

The hearty coöperation of the various boards of health, public sanitary authorities, sanitary associations and societies, and of physicians who may feel an interest in the work, is asked to achieve and perfect the aims of this investigation.

No compensation can be offered for this coöperation other than to send, free of cost, the publications of the Bureau bearing upon climatology and its relation to health and disease to all those who assist in the work.

Coöperation will consist in sending to this office reports of vital statistics from the various localities. That these reports may be of value, it is evident to all that they should be accurate and complete, and be rendered promptly and regularly. Blank forms of reports have been prepared so as to occasion as little trouble and labor as possible on the part of the reporter, and will be furnished by the Bureau on application.

At the very beginning of the investigation it is not possible to outline precisely the channels through which the results obtained will be made public, but it is hoped to publish soon a periodical devoted to climatology and its relations to health and disease. The publication will probably resemble in size and general appearance the present *Monthly Weather Review*, the subject matter being, of course different.

More detailed information will be furnished on application.

MARK W. HARRINGTON, Chief of Bureau.

#### ANONYMOUS COMMUNICATIONS.

We beg to announce once more to correspondents that anonymous communications can not and will be noticed or published in the JOURNAL. We have received a number of them in the last two weeks. A gentleman writing a communication attacking any one, should be willing to put his name to it for the information of the editor, even if not for publication. Some of those recently received we would have printed in the Correspondence column with pleasure, but as the author did not give any clue to his identity we were unable to use them.

### CORRESPONDENCE.

#### Medical Medals—Request for Assistance.

NEWPORT, R. I., Jan. 15, 1895.

To the Editor:—In the course of an enumeration of the medals illustrating medicine that have continuously appeared in the *American Journal of Numismatics* since January, 1889, several questions have occurred which I have failed to settle, and concerning which I shall be very glad for aid.

British America: Dr. Richard Noble Starr, of Caradoc, Canada. What were his dates of birth and death? Dr.

Orrin C. Wood, of Montreal. His middle name, and dates?

Central America: Dr. Perfecto G. Bustamente, of Gaudajajara, Mexico. His middle name, and dates?

South America: Dr. Alacombe, Puerto Cabello, Venezuela. Who was this person? If a medical man, his dates and full name? Dr. Pedro Ascarrinus, of Bolivia. His dates and city of residence? Dr. Juan Adriano Chasas, of Asuncion, Paraguay. Was he a physician or a lawyer? If the former, his dates?

The United States: Dr. C. P. Bronson,\* an apparently irregular ophthalmologist. What were his full name, his dates and his residence?

Dr. Selleck, connected with Chesebrough, Stearns & Co., of New York. Who was he and what his full name and dates?

United States Medical Colleges: The medals have been described of the Medical College of Alabama, (Nott); Medical Department of Yale University, (Campbell); Harvard University, (Boylston); one of those of Medical Department of Long Island, C. H. (Dudley); one of the two of Medical Department of Rutgers College (Rutgers); College of Physicians and Surgeons, N. Y. (Harsen); University of City of New York (Mott, 2); Sterling Medical College; Jefferson Medical College (Toner); Alumni Medical Department, University of Pennsylvania; Anat. and Phys., Amherst College (Sawyer); Hahnemann Medical College of Philadelphia (2); Eclectic Medical College of New York (Newton); Missouri Dental College (J. Hunter); and New York College of Dentistry (2).

Of the following, descriptions are desired. Where, instead of being wholly "struck," they are partially or entirely engraved the fact should be stated, as the last of these conditions is not recognized by numismatists: Medical Department of University of California; Medical Department of University of Louisville; Missouri College of Medicine; Baltimore Medical College; Medical College of Virginia; Medical Department of Hampden Sidney College; Medical Department of Long Island C. H. (second medal); Medical Department of Rutgers College (citizen's medal. Who was this "citizen of New York?"); Woman's Medical College of Chicago; Woman's Medical College of Baltimore; Columbia Veterinary College, New York; California College of Pharmacy; Maryland College of Pharmacy; Philadelphia College of Pharmacy; Cincinnati College of Pharmacy; Alumni St. Louis College of Pharmacy; College of Pharmacy, City of New York; and Pharmacal Department of Vanderbilt University.

United States Hospitals: The medals have been given of St. John's Guild Floating Hospital, New York, (2); German Hospital, New York; Methodist Episcopal Hospital, Philadelphia; United States Naval Hospital, Portsmouth, Va.; National Asylum, Augusta, Me.; Boston City Hospital Training School for Nurses; Bellevue Hospital Training School for Nurses, New York; Mt. Sinai Hospital Training School for Nurses, New York; Philadelphia Woman's Hospital Training School for Nurses; University of Pennsylvania Training School for Nurses; Waltham, Mass., Training School for Nurses; St. Barnabas (Nurses') Guild; Nederland Israelitish Sick Fund, New York; Washington Kranken Unterstutzungs Verein, New York; Medical Charities, Philadelphia; and of the United States Sanitary Commission the following: Citizens' Volunteer Hospital, Philadelphia (2); Union V. R. S. Fair, Philadelphia, 1863; Nantucket, Mass., Fair, 1864; New York Fair, 1864; Philadelphia Great Central Fair, 1864, (4); also Howard Association, Norfolk, Va., 1855; Savannah Banner Association (Yellow Fever), 1876; and Howard Medical Corps, Memphis, Tenn., 1878.

United States Medical Societies: I have given the medals of AMERICAN MEDICAL ASSOCIATION, (2); Ninth International Medical Congress, 1887, (2); Columbian Dental Congress,

Chicago, 1893; Louisville Medico-Chirurgical Society; and American Pharmacal Association (Block House, Pittsburg). There is another of the last of these institutions, and one of the Medical Lyceum, Philadelphia, 1808, about which I am still in doubt. Concerning that of the World's Hygienic Exposition, Chicago, 1893 (struck in Belgium), I have but recently ascertained.

Information concerning any medical medals, not indicated above, will also be duly valued.

HORATIO R. STORER, M.D.

\* C. P. Bronson, M.D. Lived in Louisville, Ky., was a traveling lecturer on Elocution, and published a book on the same.—ED.

### Department of Public Health.

CHICAGO, ILL., Jan. 22, 1895.

To the Editor:—It is hoped that the present session of Congress will make suitable provision for substantially carrying out that portion of the President's suggestions embodied in his message in December last, wherein he recommended that a "National Health Bureau be established." And it does not seem that any very great amount of additional argument should be necessary to bring about this important step of legislation.

In a few weeks, the present Congress will be "history." Before its demise, it might do something in the way of genuine reform in public health matters, and the well-known maxim, "*Salus populi suprema est lex*," prevail.

If, on the other hand, the present Congress should interpose dilatory objections and pass this measure by, without creating such a branch of our federal government, for obvious reasons it appears to the writer, legislation with the delays liable to occur in future that will be necessary to carry this through to a successful termination, may require two years longer before it is done. This not improbable delay therefore may involve serious consequences to the national health, as well as prove disastrous and detrimental to the commercial interests of our country, of which enough of the latter has already occurred to satisfy the people for generations to come. In a word, then, it is a condition that confronts us as members of a noble profession having at heart the welfare of the nation.

More than ten years ago (*vide* Proceedings of the Chicago Medical Society, September and October, 1884) expediency and timely action was urged upon our National legislators in this direction. It appeared then, as it does now, that there is a sanitary work which can be done and exacted by the National government, *pro bono publico*, of local or municipal boards of health who can not be made to comply, or who will not comply with the request of another board of equal importance, as has been the case a number of times within the past few months, in at least one of our large cities where the chief executive officer of the Health Department refused absolutely to furnish reports regarding smallpox. What good was to be gained by suppressing the truth concerning this greatly dreaded malady is beyond my comprehension.

This proposed department of the government, with a medical secretary of the same, will not only be in concord with, but coöperate in friendly professional intercourse with other health organizations, sanitarians and scientists, and in a more methodical manner it is believed it will be the means of preventing an outbreak of any of the pestilential diseases throughout the country, as well as to prevent the introduction of them in the larger cities or in different portions of the States of the Union. Or, in case any form of disease of a contagious or infectious nature should get a foothold, efforts to suppress it if it be of endemic character, or epidemics of all kinds would be more thoroughly accomplished

and sooner brought under control. To accomplish this, the secretary of this proposed department should be clothed with, or granted full power for the investigation of epidemics and preventable diseases, and be provided with necessary funds for this specific purpose.

Last year, Prof. C. B. Comegys, M.D., of Cincinnati, was obliged to resign the chairmanship of the special committee of the AMERICAN MEDICAL ASSOCIATION appointed for the above purpose. For four years he labored assiduously and did much toward bringing about this greatly desired end. Dr. Comegys is entitled to great honor and credit for his diligence and painstaking labors in this matter, and he is still an active member of the committee. The committee which has had this subject under consideration has profited by the experience of its former chairman and his colleagues and now has at its head a gentleman who is equally well known in sanitary matters as his predecessor, Dr. Jerome Cochran, of Montgomery, Ala., who with the assistance of his coadjutors if all signs point correctly, will ably present this important subject to the Baltimore meeting in May next. Unless the medical profession, and the press, both medical and secular throughout the United States work hard and speedily impress upon Congress the necessity of passing the bill prepared by Dr. Comegys and his fellow-committee men, or at least secure favorable report from the committees appointed by both branches of Congress, this measure will be lost.

Why can not Congress gracefully create this apparently inexpensive branch of the government with a medical secretary of same, and a grateful country will be their reward.

Let the profession be united on this subject and invoke the press and its efforts and appreciation of the country's need in this direction. I doubt if there be any who deny that such a law should be enacted. By so doing, consistent agitation on our part will not have been in vain.

Very truly yours,

LISTON H. MONTGOMERY, M.D.

### PUBLIC HEALTH.

**Disinfection of Barbers' Tools.**—Blaise remarks, in *Annales de l'Hygiène*, that as certain diseases are transmitted by the tools used by barbers and hair-dressers, it is important to wash and disinfect them each time after being used. As to the agents—carbolic acid kills the microbes effectually but its disagreeable odor precludes its use; boiling water rusts the instruments, even if nickel-plated, since the cutting edges are not plated. Blaise thinks the best method is to dissolve 10 parts of carbonate of potash or soda in 100 parts of hot water and immerse the instruments in this solution; they leave this bath brilliant and free from oil. Some of the essential oils may also be used, as many of them possess well established microbicidal properties. There are also creolin and benzoic and thymic acids, whose use is widespread and their antiseptic powers incontestable.

**The Antitoxin in France.**—Preparations on a very complete scale will be completed by the close of this month, whereby the whole of France will be furnished with an adequate supply of the Roux-Behring serum. The State has voted an annual sum of 100,000 francs to the *Institut Pasteur*, 20,000 of which are allotted to the vaccination department of the Academy of Medicine and the remainder is to be used for the propagation and gratuitous distribution of the diphtheria antitoxin to charitable institutions. It is estimated that a stud of from 130 to 140 horses will supply all the serum required for the entire population of the country; that the entire cost of their care and maintenance, the preparation

of the serum and postage upon the tubes, will not exceed 180,000 francs—of which sum the State appropriation contributes 44 per cent., leaving 100,000 francs to be made up by the sale of the serum to those able to pay for it, and by municipalities and departments who will defray the expenses of maintaining one or more animals at the *Institut*—the department of the *Bouches du Rhone*, for example, will maintain six horses for its own supply. The annual expense is computed at 1,000 francs per animal, and this will secure a monthly supply of 150 injections of 20 c.c. each.

**Contagious Diseases.**—Except influenza the contagious diseases seem to be on the decline throughout the country generally. In isolated localities diphtheria is as prevalent as in the closing months of last year, but its epidemic tendency in the large cities has subsided. So too with smallpox; Secretary Wingate of the Wisconsin State Board of Health, reports only 13 new cases, with no deaths, during the week ended January 19; in the State at large during the same period, 3 cases, 1 death, were reported at Mishicott, 4 cases in Gibson Tp., 2 cases at Two Rivers, 1 case, 1 death at Fond du Lac and 1 case in Fountain Tp. Dr. F. W. Reilly, who has been placed in charge of the Contagious-Disease Bureau of the Chicago Health Department, reports the total number of new cases in that city for the first twenty-two days of January, as follows: Reported by physicians and inspectors, 129; found by inspectors and not previously reported—convalescent, 2, dead or dying, 6; total, 137. Of this total, 128 cases were removed to the isolation hospital; 1 case was isolated at residence; the 2 convalescents were disinfected and the dead and dying were taken charge of by the inspectors, the premises disinfected and the exposed vaccinated. The hospital statistics for the month are as follows: Remaining at midnight, Dec. 31, 1894—84; admitted, Jan. 1—22, inclusive,—128; total to be accounted for, 212; discharged convalescent, 78; died, 32; remaining, 111. Mortality per cent., 15.5.

**Sanitary State of Calcutta.**—The report for the year ended March, 1894, of Dr. N. J. Simpson, Medical Officer of Health for Calcutta, contains some interesting facts. The barometric pressure during the year oscillated between a minimum of 29.58, in July, and a maximum of 30.04, in December. The mean temperature for the twelve months was 76.95 F., with a maximum of 88.55 and a minimum of 63.95. While all the months of the year are remarkable for a very marked degree of humidity, the months from May to September are the true rainy months. There was much more rain than usual—in December only was there no precipitation. The births reported numbered 13,492 or 19.7 per thousand; this is higher than for the preceding five years, during which it varied from 18 to 18.6 per thousand; the Mahomedans are always the least prolific. The deaths numbered 20,113—a rate of 29.5 per thousand for the year, as against 20,180 for the previous year. The different populations as indicated by these figures of births and deaths—*Journal d'Hygiene*—will not be overlooked. The number of births and the birth rate indicate a population of 365,592; the number of deaths and death rate indicate a population of 593,333. In the Mortality Table of Foreign Cities, *Abstract of Sanitary Reports*, the population of Calcutta is estimated at 681,560; Mulhall (1892) reports the population by the official census of 1891 to be 840,130. Separating the city from the suburbs the following are the death rates from 1889 to 1893: Urban Calcutta, 26.4 per thousand (25.9 in 1893-4); suburban Calcutta, 37 per thousand (37.1 in 1893-94). It is worthy of note that the deaths from cholera in 1893-94 numbered only 273.

**School Diffusion of Infectious Diseases.**—In an analysis of deaths from diphtheria in London during the last thirty years, Mr. Shirley Murphy has shown that, comparing the ten years, 1881-90, with the previous decennium, there was an increase of diphtheria mortality at all ages, but most marked at the 3 to 10 years age-period. Mr. Malcolm Mor-

ris, the newly appointed editor of the *Practitioner*, adds that this general indication—that the ominous increase of fatal diphtheria has taken place mainly among children of school age—is further borne out by the mortality statistics of 1891-2-3. Comparing 1891-93 with 1861-70 it is found that the diphtheria mortality has risen 196 per cent. taking all ages; but while the increase is only 53 per cent. at ages over 10 years and 173 per cent. at ages under 3, it is no less than 309 per cent. at ages from 3 to 10. A connection is established between this increase and the operation of the Elementary Education Act of 1871, and Mr. Morris says: "It is clear that part of the price which has to be paid for the inestimable boon of universal elementary education is an increased facility for the diffusion of certain infectious diseases, a facility which has not been entirely neutralized by all the precautions which the several authorities concerned have been able to bring to bear, even with the assistance of compulsory notification." The discussion and comments add weight to the recommendations which the health authorities of Boston, Chicago and some other cities in this country, have tendered to school boards and boards of education. In brief, these are that all interior surfaces of school buildings which children are likely to touch should be washed at least once a week during the school year with the mercuric chlorid solution; that the use of slates and pencils and of slate sponges should be abandoned for pencil and paper—the wetting of the pencil tip with the tongue or the putting of the pencil in the mouth to be forbidden; and that the floors of school rooms, passages, stairs, etc., should be strewn before sweeping with sawdust wet with the disinfecting solution and the sweepings burned at once.

**Creosote Poisoning by the Therapeutic Dose.**—A fatal case of creosote poisoning by the therapeutic dose is reported, the result being attributed to the use of milk as a vehicle. The drug was prescribed for a female patient who took three 6-drop doses in twenty-four hours. Soon after the third dose she exhibited symptoms of intense gastro-intestinal irritation, accompanied by anesthesia and partial paralysis of the soft palate and vocal cords, and, moreover, presented erosions of the buccal and pharyngeal mucous membrane, albuminuria and signs of heart failure; her breath had a strong odor of creosote and she died in a week. The necropsy revealed extensive bloody suffusion of the stomach and intestines and ulcerations of the esophagus and of the pylorus, fatty degeneration of the liver, acute nephritis and hyperemia of the brain. Zanolski, who reports the case in the *Centralbl. f. Inn. Med.*, thinks the poisoning was due to the mode of administration; creosote is insoluble in milk, and acts as though given alone. He asserts that no other case of idiosyncrasy for the drug has been observed, but advises to begin its exhibition with doses of one or two drops and proceed to larger doses with caution.

**Influence of Etherization upon Temperature.**—Angelesco reports a series of observations in *Le Progres Medical* which he made on fifty patients in Professor Chaput's service. He arrives at the following conclusions: 1, the temperature is lowered during the whole of the anesthesia; 2, this lowering presents an oscillation much more pronounced at the beginning of the anesthesia—in the first hour the decrease varies between 2 degrees and 2.5 degrees, in the second hour it is less marked, only some tenths of a degree, and this difference between two consecutive temperatures is most marked in the first and second quarter hours, 0.7 to 1 degree in the first, and 0.4 to 0.5 degree in the second quarter; 3, the decrease continues very slightly during the profound sleep following anesthesia, varying between 0.1 and 0.3 degree; 4, after waking the temperature rises, following an inverse curve to the first. The oscillations, feeble at first—0.1 to 0.3 degree—become stronger as consciousness is regained and when this is nearly restored the oscillation means are 0.7 to 0.8 degree. Besides all other causes producing lowered temperature after anesthesia the author thinks that the diminished temperature,—lower with ether than with chloroform,—points to a very marked vasodilatation in the former case. The face of a patient under ether narcosis is nearly always congested; chloroform, on the contrary, produces vaso-constriction, as proved by the pale face.

## MISCELLANY.

**A Curious Legacy.**—A Parisian artist recently attempted, unsuccessfully, to commit suicide. He left a will bequeathing his body to the Zoölogical Gardens for food for the lions and tigers. The next attempt was successful. This time he left his body to the Academy of Medicine, which refused the legacy, and the body was turned over to the family.

**Chloroform the Favorite.**—*Les Nouveaux Remedes* has compiled the statistics of 52,475 administrations of anesthetics, with the following results: Chloroform, 33,083; ether, 11,669; A. C. E. mixture, 3,896; bromid of ethyl, 2,986; Billroth's mixture, 750; nitrous oxid, in dentistry, 91. Chloroform was used in 63 per cent. of the total administrations; ether in 22 per cent., and all others combined in 15 per cent.

**A Sign of Hereditary Syphilis.**—At the French Congress of Dermatology and Syphilography (*Rev. Int. de Med. et Chir.*), M. Jullien mentioned a malformation of the jaws which seemed to him to be characteristic of hereditary syphilis. It consists in the projection of the upper jaw beyond the lower, either all around or only in front. He has observed this ten times; in nine cases it was connected with manifestly hereditary syphilis; the tenth case was simply suspicious.

**Faculty of Medicine of Vienna.**—In this winter's semester the Vienna Medical Faculty contains (*L'Union Medicale*) twenty-eight ordinary professors, thirty-nine extraordinary professors and eighty-two privat-docents and assistants. In the last semester there were 2,427 medical students—nearly half the students in the whole University. Of these 1,584—119 less than for the corresponding period in 1893—were ordinary students, 322 extraordinary and 521 special.

**French Congresses of Surgery and Internal Medicine.**—The ninth session of the French Congress of Surgery will be opened Oct. 21, 1895, in the Faculty of Medicine. The topics for discussion are: 1, surgery of the lung (except the pleura); 2, on early or late operative interference in solutions of bony continuity (except the cranium). The second session of the Congress of Internal Medicine will be held at Bordeaux, either in August or September, 1895. The subjects are: 1, On infectious myelitis; 2, the relations of the liver and the intestine in pathology; 3, on analgesic anti-thermic agents.

**Toxins Treatment of Sarcoma.**—In a study of a few suggestive cases (*Medical Recorder*) Dr. Edmund Andrews details two cases of sarcoma treated with the mixed toxins of streptococcus erysipelatosus and of the bacillus prodigiosus. He concludes that these two cases, with some others similarly treated, show that these toxins have a power analogous to that of tuberculin; that as tuberculin is capable of causing the death of tuberculous tissue, so the toxins have the same effect on sarcoma. Nevertheless, "so far as these two cases go, it would seem that the destruction of very large sarcomata by these means in weak patients is apt to terminate in fatal exhaustion." The writer thinks that probably tumors of medium or small size might give more successful results.

**Anatomy and Art.**—Dr. Robert Fletcher discussed the relation of these subjects in an able and interesting way in his annual address as President of the Philosophical Society of Washington, D. C., December 12, last. Every paragraph of his essay, now published in pamphlet form, scintillates with notes, suggestions, references and anecdotes drawn from the history of art. Taste in art is not inherent in man; its culture requires long study, close observation and familiarity with the best masters. By its brief review of the work of these masters, Dr. Fletcher's address will do much for the

cultivation of artistic taste in those who give it the attention which it merits. His conclusion, that an acquaintance with muscular anatomy by dissection, though to be recommended as useful, forms but a comparatively unimportant part of artistic anatomy, is fully borne out by the consideration that, "The noble works of Phidias and his contemporaries or successors were in existence long before the time when Hippocrates began the work of rescuing medicine from the priests and made a first imperfect sketch of anatomy."

**Expressions of Pain as Evidence.**—It is well settled, declares the Appellate Court of Indiana in the case of *Anderson v. Citizens' Street Railway Company*, decided Nov. 27, 1894, that whenever the bodily or mental feelings of a person are material to be proven, the usual expressions of such feelings made at the time are original evidence. The statements or representations of a sick person of the nature and effect of a malady or injury under which he is laboring, or expressions of existing pain, it therefore holds, are admissible as original evidence; and this is so whether they be made to a medical attendant or other person.

**Liability to County for the Support of Insane in New York State.**—It has been held in New York (*City of Albany v. McNamara*, 117 N. Y. 168) that a person receiving aid as a poor person from the officers of the poor in a city or county, in the absence of any representations on his part as to his responsibility or physical condition, incurs no liability to repay the amount expended on his behalf. That doctrine, the general term of the Supreme Court now holds in the case of *Oneida County v. Bartholomew*, decided November, 1894, applies, in the absence of any statutory provision to the contrary, where an insane person is supported at the county insane asylum as a poor person. Under such circumstances there is no liability on the part of the person receiving the support, or on his estate, to repay to the county the expense.

**Therapeutic Value of Seine Water.**—An item has been extensively copied in medical journals of late, giving the number of animals found in the Seine, which reminds the *Gazette Medicale De l'Algerie* that in 1775 a work was published entitled, "Physical, Chemical and Economical Dissertation on the Nature and Salubrity of the Seine Water, by M. Parmentier." This author declares that there is no materia medica or dictionary which does not say something on the properties of the water from the Seine. Some authors also mention it in their works. The Count of Forbin, among others, says in his memoirs that, being affected with violent colics in Paris, he only found relief and a cure by the abundant use of Seine water, by baths and drinking it. "Many officers of rank were only cured of insupportable headaches, phlegms, and nerval affections, by taking by my advice a pint of the water, cold, early in the morning." Our contemporary thinks the Faculty should bring this remedy to the notice of the profession.

**Can Patients Smoke?**—Jankau (*Zeitsch. f. Krankenpflege*) thinks that patients may be permitted the moderate use of tobacco, especially if they are used to it. All those with surgical disorders he says, may smoke, except those convalescing from operations on the bladder or abdomen. It should be forbidden in affections of the eyes, nose and pharynx. Among patients with medical disorders, those with peritonitis and typhoid affections should not use tobacco. In gastric diseases they may smoke if the smoke is filtered. In cardiac affections very little smoking may be allowed. It is sometimes indicated in pulmonary affections and also in syphilis. In nervous affections it is difficult to say—sudden stoppage of tobacco is inconvenient and, on the other hand, in cardiac neuroses smoking is to be permitted only when the smoke is filtered. The author says smoking should not be permitted in wards with many patients and that the best time for it is several hours after meals.

**Treatment of Chloroform Asphyxia.**—At a recent *seance* of the Paris Academy of Medicine, reported in the *Bulletin of the Academy*, Labbé said that in apparent death, from chloroform, he was firmly convinced that artificial respiration

should be persevered in for a long time and instanced many cases in support of this advice—particularly one in which he had kept up artificial respiration for twenty-seven minutes and was finally rewarded with a remarkable success. Lately, however, he had used rhythmical traction of the tongue, suggested by M. Laborde, in the case of a child who, soon after beginning the chloroform inhalation, became asphyxiated. Death seemed absolute, the pupils were dilated to the utmost. As soon, however, as he began the rhythmical traction of the tongue the patient returned to life with marvelous rapidity; it was a genuine resurrection. He believes this method is preferable to artificial respiration, as it is easier and much quicker. Professor Verneuil said that for some time he had used only lingual traction, alternating with flagellation of the epigastrium with a wet towel.

**A Proposed Hospital for the Homeopathic Insane.**—A bill has been introduced in the Illinois Legislature providing for the establishment of a hospital for the insane to be managed on "homeopathic" principles, whatever they are. The existence of the "homeopathic" sect shows some mental aberration, but this is the first public admission we have seen that any considerable proportion of them required confinement. There is nothing infinitesimal about the proposed appropriation, as the bill provides for an expenditure of \$400,000.

**Journal of the American Public Health Association.**—No. 1, volume 1, of this *Journal*, published quarterly, lies on our table. It has a handsome face, and like all of the publications of the Association is well printed. The papers in this issue comprise the larger proportion of those read at the Montreal meeting, which have been fully abstracted in this *JOURNAL*. We congratulate the Association upon their handsome publication, and believe that it will have a great field in the advancement of sanitary science on this continent.

**The Absorption of Guaiacol.**—The question whether the quantity of guaiacol eliminated by the urine in a given time, is the same when the drug is employed pure, or when mixed with glycerin, has been studied by O. Sturbe, whose tests were made in a series of skin paintings. That observer has found that pure guaiacol is absorbed more quickly than when mixed with glycerin or oil of almonds, and that the glycerin embarrasses absorption considerably and uniformly retards it, notwithstanding that the oil of sweet almonds retards absorption at first, but left alone, absorption is effected in from one and one-half to two hours easily enough.—*Courrier Médical*.

**The Proposed Testimonial to Sir Henry Acland.**—The friends of Sir Henry Acland propose to take the opportunity of his retirement from the Regius Chair of Medicine to "mark their appreciation of the great services which he has rendered to Oxford and the country at large and the kindness he has done to individuals. To him is mainly due the foundation of the schools of natural science in the University, the initiation of teaching in biology, and the high standard maintained by the Oxford medical degrees. There are few persons who have not profited by his labors in the study of sanitary requirements and of the laws of public health."

Subscriptions will be received by Parsons & Co., Old Bank, Oxford; London; and County Bank, Oxford; Wooten & Co., Oxford, and Gillette & Co., of Oxford. It is proposed to make provision from this subscription for the increased usefulness of the Sarah Acland Home for Nurses.

**Relation Between the Physician and the Pharmacist.**—Mr. Wm. J. Evans, of New York, made the following response to the toast assigned him at the banquet of the Mississippi Valley Medical Association, at Hot Springs:

"When the ultimate Jenner, Lister, Pasteur, Koch, Behring, and Roux in the ultimate institutions of preventive medicine have developed that which shall be ultimate materia medica and pharmacology, it may be found that the last

branch of study to approach an exact science will have given its fuglemen such fame as to prove that it was certainly not the least among their notable achievements.

"In representing the chemist and the pharmacist, I feel obligated to say for them that they are conscious that no man liveth unto himself. Their occupation may be one which they like or dislike, but it is an occupation second only to that of the practice of medicine in the matter of making society possible. The public health is public wealth, and the grandest aggregation is the possession of valuables by the valiant. In expecting that the medical men will adopt the motto, let the standard be so high that he who fails may say, 'What I aspired to be and was not, comforts me.' The chemists and pharmacists are more than happy in adopting the motto, 'There is no office in this needful world but dignifies the doer if well done.' Will it be too much for the patient to expect, who is our nearest and dearest relation, that both schools shall adopt the motto of the great painter, who said: 'Whatever of strength, whatever of dignity we have within us, will dignify and make strong the labors of our hands. Whatever littleness degrades our spirit will lessen them and drag them down; whatever noble fire is in our hearts will burn also in our work; for as we are, so our work is, and that which we sow in our lives, that without doubt we shall reap for good or ill in the strengthening or defacing of whatever gifts have fallen to our lot.'

"Gentlemen, I have much pleasure in asking you to enlist with the chemist and pharmacist in a pledge to contribute to that which shall live after the fads and fallacies of pharmacy are forgotten."

**Tours of Duty in the Army Medical Service.**—The following circular was issued, Jan. 9, 1895, from the office of the Surgeon-General of the Army:

The tour of duty for medical officers below the rank of Major at the following stations will hereafter be two years, which time will be considered as equivalent to a full tour of duty in the Military Department in which the several stations are located.

This, however, must not be considered an absolute rule, as the interests of the service may frequently call for a change of station within the department or to another department before the regular tour of duty has expired, and circumstances may sometimes make it advisable to extend the tour of duty of a medical officer beyond the time specified.

GEO. M. STERNBERG, Surgeon-General U.S. Army.

Approved:

DANIEL S. LAMONT, Secretary of War.

Outside of the announcement by Surgeon-General Sternberg in 1893, that those captains of the Medical Department who were nearing their examination for promotion would be assigned for a year as attending surgeons in certain cities, to afford them facilities for study and professional improvement, the circular just issued is the first formal intimation given to Army medical officers of the probable length of their tour of duty at any specified station. Since the close of the civil war, it has generally been understood that the Surgeon-General in assigning officers to duty considered the locality and character of their previous service. A tour of duty in the West has usually been followed by an assignment to an Eastern post; service in the field or at an isolated post by service at some military station near a city where the refinements of civilization with opportunities for professional culture might be enjoyed. The length of the tour at one post or in one department was four years, except for junior officers whose service in the East was limited to two years at a time. The circular just issued modifies this by restricting the two years term to twenty-two stations, among which are included the best of Eastern and the worst of the Western posts. Instead of moving the junior officers from all the Eastern stations, after two years service those only

will be moved who have enjoyed the advantages presented by the vicinity of large cities; and instead of having a four years tour for all the Western posts, the young officer who has endured the discomforts of such places as San Carlos and the Texas posts, will be relieved at the end of the two years term of service. By this arrangement the number of moves and consequent expense of transportation will be lessened, and the advantages of the good stations and the disadvantages of the bad ones will be more equably distributed than by the method previously in force.

**Statistics of Intestinal Resections.**—E. Becker publishes in *Zeitsch. f. Chirurg.* the statistics of resections of the intestines in Trendelenburg's clinic at Bonn for the last ten years. They number thirty-three, as follows: Five for strangulated hernias, eleven for artificial anus following strangulated hernias, two for ileus, one for appendicitis, four for fecal fistulae following perityphlitis, one for fecal fistula from a ruptured colon, three for cicatricial strictures due to tuberculosis and six for tumors. These thirty-three resections resulted in twenty-one cures. An examination of these statistics shows that an artificial anus gives better results than intestinal resection in the treatment of strangulated and gangrenous hernia. Also that in the Bonn clinic it is the rule first to create an artificial anus and if necessary later to resect the intestine.

**Association of Agricultural Chemists.**—The Proceedings of the Eleventh Annual Convention of the Association of Agricultural Chemists, has just been issued from the Government Printing Office, Washington, D. C., as Bulletin No. 43, of the Division of Chemistry of the Department of Agriculture, the Chief of this division, Dr. H. W. Wiley, being the able secretary of the Association. The meeting of which this is the record was held in Washington, D. C., in August last. The objects of the Association are to secure uniformity and accuracy of the methods, results and modes of statements of analysis of fertilizers, soils, cattle foods, dairy products and other materials connected with agricultural industry; and to afford opportunity for the discussion of matters of interest to agricultural chemists. The original constitution adopted in 1884, proposed as well to secure uniformity in legislation; but two years later the Association considered it best to confine its work to matters of a purely scientific character. Its field of inquiry, as shown by the present volume, covers all branches of agricultural chemistry. Uniformity in analyses is obtained by the adoption of methods which have stood the tests of coöperative investigation by committees and full consideration by the Association, which methods are thereafter regarded as official. Processes for the estimation of phosphoric acid, nitrogen, potash, sugar, foods and feeding stuffs, butter, milk and fermented liquors were adopted at the last meeting and are given in full in the report, which contains also many interesting papers on laboratory work on these same subjects. A valuable part of the volume is the report of the Abstract Committee which in 629 abstracts gives the substance of all important articles published during the past two years in the chemical and agricultural journals of the world. The volume thus forms a most valuable addition to the laboratory not only of the agricultural but the sanitary chemist.

**Abandonment of Mount Vernon Barracks, Ala.**—Mount Vernon Barracks, Ala., one of the nine posts recently abandoned under War Department orders, was situated twenty-nine miles north of Mobile, on a hill three miles west of the Mobile River and 150 feet above its level. It was established in 1873 by troops from Mobile barracks in view of danger from yellow fever at the latter station. Thirty-five acres of the reservation were inclosed by a brick wall, sixteen feet high, within which most of the buildings belonging to the post were aggregated. The barrack building was of a more imposing character than those of any of the other recently

abandoned posts. It was a substantially built three-story brick structure, 120 by 40 feet, with a tower four stories high and a porch with stairways affording entrance to each floor. The second and third stories were used unpartitioned as dormitories, giving over one hundred square feet and 1,000 feet of space to each man of their average occupancy. The ground floor was used for kitchen and mess hall purposes. The officers' quarters consisted of one- or two-storied brick cottages, each with an inclosed yard. The offices, guard house and magazine also were of brick. The storerooms were frame buildings on brick piers. The hospital, a frame structure, excellent in its appointments, afforded space for fifteen beds, few of which were ordinarily occupied. The dry earth system of sewage disposal was in use, with iron draw boxes in outhouses; but had the existence of the post continued for a year or two longer a sewerage system would no doubt have been introduced following the new water supply which is described in the report of the Surgeon-General for the past year: "The hydraulic ram has been replaced by a steam pumping engine, by which the water is raised to an iron tank of 36,000 gallons' capacity on the summit of the hill occupied by the buildings of the garrison. This tank is elevated fifty feet from the ground and 150 feet above the level of the pumping station. From this the water is conducted by four-inch mains to the barrack rooms, kitchens, officers and non-commissioned staff quarters and the men's water-closets and bath-rooms; also to the barracks of the Indian company and to hydrants in the camp of the Indian prisoners."

Some notoriety was given to this post by its selection as the place of imprisonment for Geronimo's band of Chiricahua Apaches. At first little attention was paid to the condition of the prisoners, but the high death rate prevailing among them led to inquiry as to its cause. Consumption among the older members of the community and diarrheal affections among the younger, occasioned the mortality, aided by the gross ignorance of the people and in many cases by their efforts at cure. Every endeavor was then made by the officers in charge to reduce the mortality. Excellent quarters were built for the prisoners. The frame cottages constituting the Indian village, about three-quarters of a mile from the post, were arranged in streets on each side of a central square. Each cottage was twenty-eight feet square by twelve feet to the eaves, detached by a considerable interval from the others, provided with a cooking stove, beds, tables and chairs and kept in a condition of thorough cleanliness. At one angle of the camp was the barrack of Company "I" of the Twelfth Infantry, composed of male Indians of the military age—represented in official reports as a model of order and neatness outside and inside. There was also built for the village a frame hospital of twenty beds, one-storied, shingled and with an inclosing veranda with green blinds. At first the hospital had little patronage, the Indians preferring to be sick in quarters and prescribed for by their own wise women and medicine men, but in progress of time they became as much accustomed to the hospital and the doctor as to the wash basin, bathing pond and cooking stove. Nevertheless, the death rate did not fall. During the first five years the rates per 1,000 living were 55, 51, 110, 146 and 110. They increased notwithstanding the care given to the sanitation of the camp. The Surgeon-General of the Army considered the mortality due to change of habits and that if the Indians were permitted to live on a larger reservation, preferably in a mountain country, their death rate would probably fall to its normal of about 40 or 50 per 1,000. The Indians were moved to Fort Sill, Indian Territory, and the post of Mount Vernon Barracks was abandoned December 4, last.

**The Organs and Functions of the Cell as Described by Watase.**—We are learning to look to the cell as a highly intricate organism with organs of complex structure set apart for the performance of definite functions. The boundaries of morphologic injury have, in the last few years, passed beyond the cell into the problems of the cytologic organs. Many suggestive questions of this line of research have been dis-

### THE ELEMENT OF HABIT IN GYNECIC DISEASE.

Read at the Seventh Annual Meeting of the American Association of Obstetricians and Gynecologists, at Toronto, Canada, Sept. 19, 20 and 21, 1894.

BY GEO. F. HULBERT, M.D.

ST. LOUIS, MO.

IN CHARGE OF DEPARTMENT OF GYNECOLOGY AND ABDOMINAL SURGERY, WOMAN'S HOSPITAL.

"The situation has never yet been occupied by man; That has not its duty; its ideal. Yes; here in this poor miserable actual, Wherein thou even now standest; here, or Nowhere is thine ideal. Work it out, therefore, and in the working Live, believe, be free."

#### THE ARGUMENT.

1. The national endowment and conditions.
2. Primitive type to standard type.
3. The law of conservation of energy operates for, and necessitates the operation of, the "element of habit."
4. The law of conservation of energy, operating in conjunction with original endowment, insures persistence of the "element of habit."
5. The operation of the law of continuity.
6. Variation in type, acquired by change in environment operating on primitive type.
7. The law of conservation and continuity necessitate the operation of the "element of habit" in the variation in type.
8. Application of the argument.
9. Report of cases illustrating the variation in type and the "element of habit."
10. Atavism the law of therapeutics.

In the evolution of truth accomplished by the finite mind it became necessary, from the very nature of things, that the beginning should be in the simple and often error-laden method of observing, collecting and arranging those incidents termed facts, and from these by various processes of proving and testing, arriving at the knowledge of the thing sought for.

In all this there has, and always will be, the personal equation; and our experience and knowledge of this element clearly demonstrates a positive variation in type in all conditions and circumstances so universal that one is forced, if he be a seeker after truth, to become skeptical and stand askance on presentation to the results attained. While it can be readily and easily established that this variation is obedient to a universal law and order, it is not always a matter easily demonstrated that to the personal equation in large degree, if not wholly, the variety in conclusion we seem to be so abundantly blessed with, and that, too, in relation to the same facts, methods and the et ceteras of our work, must we attribute much of our delay, undoing and contradictions. If we will eliminate this factor, to the extent of abolishing the conscious acquired ego, and permit the unconscious acquired capacity, evolved from hard honest work for truth to prevail in us, there is a law in the universe, the discovery of which was, has and will ever be the greatest of all ages, that of continu-

ity or uniformity, that will harmonize all confusion and lead hard and close to the truth. This has long since been recognized by the naturalist, physicist, mathematician, astronomer and real scientist, but the larger mass of the medical world, and many of the leaders, seem to have little conception of the great blessing at hand. What a brilliant, tragically earnest demonstration the discovery of the planet Neptune was of this thought, where the independent work of four men, who reasoned in accordance with this law, resulted in at last being able to turn the lense upon the very spot in space where the planet was fixed.

We do not wish to be understood as belittling in any sense the marvelous work and progress that has been made in the past in our profession, but simply call attention to a few truths which if fully and reasonably comprehended must necessarily lead to less waste of valuable time and energy, and brush away much unnecessary and seemingly incessant contradiction and confusion. In the consideration of our theme we shall, therefore, endeavor to so approach and consider it that this philosophy may be manifest; and at many places we all can find common ground of agreement and thereby insure profit in what may follow at your hands.

As a first evidence of this, we wish to call attention to the striking suggestiveness that words convey in the consideration of any subject; and always when rightly used point to truth. We are all familiar with the words, natural, normal and standard, and I dare say many of us use them more or less interchangeably, when in truth, while allied in meaning, they are and should be specific, and when so used lead to entirely different conceptions and enforce the truths contained in no uncertain way.

Natural, is derived from *natura*, meaning *born*, *produced*, as the adjective means pertaining to the constitution of a thing; belonging to native characteristics; essential; not assumed, put on or acquired. Normal, is derived from *norma*, rule; as the adjective means according to an established course, rule or principle; conformed to a type or regular form; acquired. Standard is derived from *extendere*; to spread out, extend; and is used in the sense of that which is established as a rule or model.

Now in the comprehension of the natural conditions and endowments of the human organism, to which horn of the problem are we at once led? Manifestly, not to the normal or standard complete human organism, but to the born, essential characteristic of this organism, if we wish to find common ground of agreement: for here all elements of confusion and error are most completely eliminated and at once do we deal with that which contains within itself, in the primitive type, every energy, function and structure that in larger and more complete expression we find in the acquired organism, the human

body. In short, we can, all of us, come together at the *natura* of the acquired organism, comprehend and appreciate in common the natural endowments and conditions; and from these rise into the larger, acquired, established rules and principles, and agree at last in the spread out and extended expression.

It is entirely unnecessary before this body of intelligent and skilled minds to review and present what is the natural endowment and condition of the mass of protoplasm, or the germinal cell, save to say that therein do we see in its primitive type every energy, function and structure that later we find in larger and more extended expression in the normal or standard type; but for our purpose it becomes necessary to trace the mode, method and causation of this; for therein is contained that to which we wish to refer and especially emphasize, namely, the element of habit in gynecic disease.

We affirm, and have elsewhere in a suggestive way, more elaborately presented, that the energy at work in the primitive type is chemical, and is a direct transmutation from the energy of heat, operating upon known forms of matter, under conditions that have passed from inorganic to organic. These conditions characterized by an independence or freedom under appreciable laws; these being the law of continuity conjoined with the law of conservation of energy. So that, given chemical energy under these conditions of freedom or independence, operating under these laws of continuity and conservation of energy, upon definite elements or forms of matter, the product is protoplasm. This is the causation.

The mode and method is evolution and its conditions, under law. This implies that in the product, protoplasm, the primitive type created by the cause assigned, we must have the germ of every form of energy or activity that may subsequently be manifest in the acquired normal or standard type. The law is the same as for causation; that is, continuity and conservation. Hence to the mode and method of evolution and its rules and principles, previously termed conditions, at work under the primary laws of continuity and conservation, in conjunction with chemic energy and its manifest and latent potentials under the same laws, must we assign the products, function and structure. The necessary product from the first, therefor, being protoplasm in primitive type, from this in conjunction with the second, we must have a still higher product, the germinal cell, and from this as the name implies, obedient to the operation of the same cause, mode and method and the persistent application of the laws of continuity and conservation must we find a product of larger and more complete expression, the differentiated cell, and from this the acquired, fully expanded and spread out expression, the human organism; with all of its contained activities, functions and structure. In short, the normal or standard type.

We affirm, therefor, that the natural endowment and conditions are formed and correctly appreciated only in the primitive type; that the normal and standard are an acquired extended expression and fullness of these; that causation, mode and method being under law and productive of the primitive type, so also on account of law must the normal and standard, the acquired and extended type be a product of this natural endowment and conditions and must be obedient in all activities, functions and structures to the same law and order.

From this we can, without further argument, state our second proposition: That from the primitive to the normal and standard type, the laws of continuity and conservation must hold true, and be ever present, and in conjunction with chemic energy, operating through evolution and its conditions, stand in the relation of causation mode and method, for every activity, function and structure that may find expression in the progression from one to the other.

The law of the conservation of energy briefly stated, declares that the sum of all the energy in a system remains constant and is unaltered by any transformations arising from the action of one part of the system upon another, and can only be increased or diminished by effects produced on the system by effects from external agents; in short, a question of quantity.

On account of the position taken, it is apparent that, as far as the primitive type is concerned, in the effect observed in relation to causation there is no change; it is still, in the progression to the normal and standard, chemical; and in all the transmutations as into heat sensation, assimilation, digestion, excretion or reproduction there is no change in the sum of either individual or collective energy; they are fixed and for its system unchanged. There is change in structure and this alone, but in each do we find the exact reproduction of the primitive type, and this, as before implied, is due to the rule and principle of evolution, but involves no change in the law of conservation. The product contains no more energy or sum and is not altered by any transmutation in it, and there are no added transmutations of energy except what were in the original; it is the exact pattern and type. Evolution calls this conformation to type; but evolution is the mode and method of the product; we are dealing with the causation and the product itself. It is the operation of the law of the conservation of energy, necessitating a mode and method in conformity to what preceded. Parent and progeny are and must be exact and alike in all details and generalities, continue and extend the process and under law every parent to every progeny will be alike indefinitely.

The word habit, comes from *habitus*, meaning state, dress. Do we violate any law of logic or reason when we identify the above progression from cause to effect, by saying that herein do we find the element of habit in relation to protoplasm. We think not; and state our third proposition, that the law of conservation of energy operates and necessitates the operation of the element of habit.

The law of continuity declares that nothing passes from one state to another without passing through all the intermediate states. Such being the case in the progression from the primitive type to the acquired normal or standard type, the law of the conservation of energy must pass to the normal and standard, and operating therein must necessitate the operation of the element of habit.

The element of habit we conceive, therefor, to be that state or dress of protoplasm manifest and observed in any and every stage of the progression from the primitive to the acquired type, as related to energy, function and structure; which insures the repetition or recurrence at any given point in the progression of the attained energy, function, and structure typical of the stage selected. In causation this is chemical in its varied potentials. In mode

and method it is the law of natural selection and, mark you, selection not simply in structure but also in energy and function.

Having traced causation mode and method in the natural endowment and conditions; identified them therein; shown their presence in and from the primitive to the standard type; stated the laws of conservation and continuity, and shown their operation and necessity therefor; identified the element of habit not only in the primitive, normal and standard types, but its necessary presence in each, and at every point in the progression from one to the other; and this necessity and operation being due to the influence of the laws of continuity and conservation; and shown that the element of habit is not only found in relation to causation, mode and method but necessarily passes to the product itself, protoplasm, and is found therein and in relation to energy, function and structure, obedient to the same law and order; the element of habit must therefor be persistent.

This leads to our fourth proposition, that the law of conservation of energy, operating in conjunction with the natural endowment and conditions, namely, evolution, insures persistence of the element of habit, due to the operation of the law of continuity; and not only must be found in and through the progression from the primitive to the standard type, but also in every and any variation that may occur.

From the foregoing, it is evident that in the further consideration of our theme we are confined to that position which considers disorders or disease, be it gynecic or otherwise as a variation in type, in relation to the natural normal or standard, and that this variation is not simply that of structure but also of energy and function. If we apply this to the standard organism or the so-called normal we do so with a certainty of plunging into complexities and confusions that are unending and lead to inconsistencies and contradictions. If we bear in mind the meaning of words, as natural, normal and standard we at once see that we must turn to the *natura*, the natural, in order to find common and sure footing in our conception of variation in type or disease. This may seem simple and unscientific, but certainly the *natura* is the thing itself; is omniscient and omnipresent, and we challenge the objection by saying that it was only when the medical mind evolved the departments of histology, microscopic pathology and bacteriology, that light was manifest and our knowledge of real utility.

Furthermore, we know that the only possible means that are capable of accomplishing a variation in type is that law of evolution termed "change in environment." If this is to be applied, either in theory or practice, to the normal and standard type, we are thrown back into the mysticism and empiricism of the "dark ages" of medicine and are compelled to comprehend cause and effect by symptoms; these may be real or counterfeit. Keeping in mind, therefore, that we are dealing with energy, function and structure as expressed in the primitive type, we state our fifth proposition, that disease is a variation in type acquired by change in environment operating on the primitive type, and that this variation and effect of change in environment is not simply in and on structure, but also in and on energy and function.

This leads to another concept, viz., that an absence of change in environment insures a persistence of the *natura*, or the acquired type, and necessitates a

persistence in progression of the type acquired through the stages of evolution to which the organism is or has become adjusted. We perceive, therefore, that the element of habit is and does become a potent factor, and that it is not only to be found in the *natura* in relation to the primitive type, but also in the acquired, be it normal or standard, and in relation to those conditions termed health or disease.

In the application of the foregoing we must keep in mind that it is in relation to energy and function, as well as structure, that our concept is to be utilized. This may seem an unnecessary refinement in diagnosis, yet without it we gain nothing in reconciliation of apparent contradictions and explanations of the enigmas of our experiences.

Who of us is not familiar with those general divisions of disease called functional and organic, and does not feel in the attempt to explain and point out differences that only a part of the phenomena are accounted for? Who of us has not witnessed those gradual modifications and alterations under the effect of some external or foreign agent in which structure or function may or may not be involved, and yet all the symptoms of the most intense organic change be manifest, and are sought and not found? and who of us has not done careful and effective work in removing evident causes for evident effects, and been non-plussed at the persistence of the phenomena we believed would disappear?

We believe the difficulty lies in the fact that we have been contemplating structure; that we have not comprehended the "trinity" of the human organism, energy, function and structure, and have not recognized the possibilities of a variation in type within the limits of the freedom or independence possessed by each in its relation to the others, as well as without. Take, for instance, the first, energy. This, we affirm, is chemical. Witness the lithemic condition; what mild or protean phenomena may be evolved from this chemic variation, and how long it may continue with only a variation in function. Witness the drugging (morphin, chloral, cocain, alcohol) the human organism has sustained, and how long continued this may be and structure remain intact. For function, witness the over-exertion, excessive changes in environment, abuses and excesses in all directions of function, and energy and structure remain typical and competent. For structure not so much can be allowed, but observe the hypertrophies, hyperplasias and atrophies, and not quantity but type and competency remain. And what part or locality in the human organism furnishes greater possibilities, or is richer in observed phenomena in any of these, than the gynecic?

Here better than elsewhere in the primitive, normal or standard type is observed continuity, conservation and evolution from the simple primitive undifferentiated, up to the completely expanded expression, working out the progression with a marvelous capacity and reserve, in all its adjustments; fulfilling law and order in its widest and most exacting demands, to the complex differentiated expression of the trinity; abiding for a season, thereby insuring persistency in law and order and type; thence back again; obedient through all to continuity, conservation and evolution. A poem in energy; a symphony in function; the culmination of a cosmos in structure. And yet there are men in the highways and byways in this day of light and possible liberty from error, whose

concept of gynecology is a speculum, a probe, absorbent cotton and iodine; a pessary; a knife; electricity; drugs; an idea or authority.

Further, in order that we may avoid misconception and confusion in considering the argument, the element of habit, from what has preceded is defined as the adjustment of any one or all the elements of the trinity—energy, function or structure, to the circumstances or conditions operating or quiescent at any given time. It is not the causation, mode or method, but is involved therein; is not the law of continuity, conservation or evolution, but a sequence thereof; being an adjustment in and due to the above, at any given time in circumstance or condition of protoplasm, either as primitive, normal or standard type, it remains in our application to show how this is manifest and accomplished. In this we do not consider it necessary to review what you all have observed and no doubt appreciate in that condition called health, and are acquainted with the variations in type within the limits of the condition, health; but to transfer this whole plan and argument into the domain of disease in every detail may not at first seem correct; yet this is precisely what we must do if we accept law and order in the universe, conceive disease to be a variation in type and believe continuity, conservation and evolution as laws in relation to causation mode and method necessarily passing to energy, function and structure. There must be analogy (we use the word with its specific meaning) or contradiction. If analogy, then truth; if contradiction, then error.

We have said that disease is variation in type; this implies change in environment. Look at bacteriology; here we have presented organisms analogous in all respects to the human organism as far as being a part of the same cosmos; with a natural endowment, obedient in causation, mode and method, energy, function and structure to the same general laws in which the culmination in expression is to a *natura* molded for and adjusted to the same objective point—self; but whose mold and adjustment is a variation in type in its trinity from that of the human organism. These, coming into relation with the *natura* of the human organism (and if we had continued observing the acquired normal standard type they would be still unknown), made possible by the analogy, there is accomplished a change in environment to the *natura* of the human organism, and this change in environment is not simply to the structure but to energy and function, and as a result of this change there is and must be a variation in type in the *natura* of the affected organism.

This variation may be confined to one, two or all of the elements of the trinity; when energy is simply modified there may or may not be any modification in function or structure. It may be transient or sustained, and may not pass beyond the confines of the capacity or reserve which needs nothing else to dispose of or tolerate the variation. In this variation we place the benign and some possibly pathogenic organisms, and find by this that our analogy carries us direct from health to disease. Passing from the pathogenic organisms that may at some time accomplish only variation in type in energy, to those that always do, and that in a degree beyond the freedom for individual variation in type, we fully enter the domain of disease and find the continuity of the progression unbroken, and the conservation in

energy absolute. Accomplish the change in environment as you may, either by direct contact of organisms, agents operating upon the acquired type through the mental, nervous, muscular, excretive, secretive, digestive, assimilative or reproductive tracts; or by agents chemical or physical, the modification is received and spent on and at the *natura*, and the effects accomplished may or may not be transient or sustained and the variation in type in energy can be likewise traced into and from the condition termed health into the condition termed disease, and not a break found in continuity and conservation, and not a single rule or principle of evolution violated. So, also, study function and structure, but time forbids. We think it correct, therefore, to say that change in environment produces variation in type. We see that disease is due to change in environment and that it invariably affects the *natura* of the human organism either in energy, function or structure or in all, and consequently is variation in type.

It is manifest, therefore, if we apply this variation to structure we have only organic disease comprehensible with always function and energy involved. This we know is not true if applied to the acquired normal or standard type; is true if applied to the *natura* or primitive type, but only in relation to each individual cell affected; for we know that structure may be seriously modified in the first, energy and function remaining typical and competent. Apply this to function, and we comprehend functional disease with or without variation in energy or structure. If applied in relation to the acquired type, we have no means of differentiating when energy and structure vary, and have no conception of the possibility of the disorder passing from the domain of the functional to the organic; applied to the primitive type this is readily appreciated. Apply the variation to energy at work in the *natura* and conceiving all the various activities of the acquired type as being transmutations from this, and much of the now incomprehensible functional domain becomes clear; immunities from and predispositions to disease are explained; acquired modifications protecting from or predisposing to variations once experienced are tangible; soil, diathesis, resistance are appreciable; the mysticism and ignorance involved in the neuroses is largely brushed away; slight ailments will obey attention; hysteria, neurasthenia, hypochondriasis, many forms of melancholia, and a host of disorders that the careless medical mind attributes to the "fool patient" will become realities; the possibility of a variation from the condition of health to that of disease, and that, too, without any appreciable cause from without will become manifest; and while we at this time can not give the variation in formulas and may not be able in all cases to correct the variation, we can, until this field has been better explored, in hearty accord with our German co-laborers, make a more correct diagnosis, and damn the therapeutics.

Appreciating disease as a variation in type, we present the last point in our argument, and that is, that the possibility always exists in disease as well as in health for the variation in type to become fixed or adjusted in its relation to the *natura* and its trinity to such a degree that it is more or less persistent. This necessarily implies a persistence if the change in environment is more or less perfect, and so long as this more or less perfect persistence of the change is operative there can be only more or less operation of

another principle of evolution, that of atavism or reversion to the original type, and consequently the disorder must be more or less persistent and appreciable.

The conclusion we reach from this is, that habit being the state or dress or adjustment attained in the *natura*, either in one, two or all of the elements of the trinity, it necessarily must pass to and be present in disease and be one of the elements in pathogenesis, pathology and pathisotherapie.

In illustration, and for the practical part of our paper we wish to present the following, the first of which is variation in type in relation to energy:

Miss A., aged 25, school teacher; five feet four inches; 115 pounds; menstruated at 13; always more or less trouble and for last six years sufferings severe; nostalgia more or less continuously; malaise and ready fatigue persistent; constipation; cephalalgia of top and back of head; vertigo at times; gastric disturbances slight, but explosive at times during menses; heavily coated tongue; skin flabby but not anemic in color; uterus in complete retroversion; density greatly modified, so much so that flexion can readily be produced in any direction; no evidence of any structural changes save slight enlargement of left ovary and moderate fixation of right; easily released; no history of any inflammatory attack at any time and no discharge save at menses; this is normal and good color. The dislocation is marked; uterus at first examination was found impacted between the utero-sacral ligaments, which was readily relieved; the patient declining operation a pessary was introduced, well fitted, gave no discomfort and apparently relieved the relaxation manifest at cervix. This patient has been under observation now for over a year, and only during the last four months has there been any evidence of improvement in the relaxation and persistent slopping of the uterine body over upper arm of pessary. Every means possible was utilized; all symptoms met; tonics and the et ceteras of the gynecologic armamentarium were exhausted and no appreciable benefits attained.

The environment was pernicious, monotonous, effective, and the variation in type was likewise persistent. It was not until we comprehended that this was in energy that we found the key to the situation; structure was certainly unchanged; function was to some extent, but when considered in relation to the *natura* it was not; the type was there but the *power* for active function through structure was not there. Considering, therefore, that the variation was in energy we could find nothing to fit the case unless it was that the chemic modification was that of lithemia. Acting upon this, and persisting for three months, we were rewarded by the first and only evidence of relief, that of general systemic well-being and decided improvement in the relaxation of the pelvic tissues, to the extent at this date of a more normal density of uterine tissue and the pessary now sustaining the uterus in position. But all along the reversion to the original type there was and is now a more or less constant tendency to return to the full expression of the variation. This, we consider, the element of habit. The adjustment of the *natura* to the variation had been so long in operation, so fixed, that in spite of the activities at work, by presentation of changes in environment within the lines of health toward this end, that it is continuously showing itself. The law of natural selection has passed from the limits of health to the domain of disease and is at work in the new adjustment; and we expect to have to contend with this element of habit until such time as the environment for health shall have been in operation so long and forcibly that the *natura* has been brought back entirely to the adjustment of the original type, and the element of habit for disease has become the element of habit for health.

Variation in type in relation to function in pure and simple expression is not frequent, but is usually met after variation in energy and structure has complicated the process, standing in relation of cause to the former and sequence to the latter.

The following case illustrates with a considerable degree of purity the type:

Miss A., age 27; single; brunette; five feet four inches; weight 115 pounds. Gives clean bill of health up to 21 years of age, at which time, following severe mental and physical strain, began to have leucorrhea, backaches, gastric reflexes, cephalalgia; pains the day before and first day of flow, gradually changing to three days before and the several days of the period. Save at the menses and the leucorrhea feels perfectly well, capable for her duties and enjoyments, and would to the casual observer be considered a healthy woman. Examination of the gynesia revealed nothing tangible or without the domain of health in relation to structure or energy. But at the menstrual epoch the picture was radically changed. There was hyperesthesia; decided enlargement of uterus and ovaries; mobility diminished and all the evidences of general pelvic stasis and hyperemia; in short, the type was congestive; here with energy typical and competent, structure unchanged, the action or function passed far beyond the type and we had all the phenomena of the first stage of an inflammation.

The variation in type had reached the point where energy was beginning to yield and this accomplished, structure would not belong in joining in the progression. Those who have had this type to deal with know full well the fixed character of the variation; how the tendency to recurrence is frequently exhibited and how slight changes in environment send the subject back again and again. Here do we see the element of habit.

As illustrating variation in type as related to structure, we point to the traumatisms, and lesions accomplished after long continued operation of variations in type of energy or function. Particularly is it observed in that class who have gone through long experiences of organic disturbance, in which evolution in structure has been accomplished, which in many instances remain more or less permanent. Even in those in which reversion to the original type has been most perfectly accomplished, do we see manifest repeated and persistently recurring attacks in which the type is again and again more or less fully expressed, and that too in the absence of the specific agent that at first produced the variation. This we consider the element of habit responding to the variation in structure. The new state, dress or adjustment is repeatedly showing itself on account of the persistent change in environment maintained by the variation in structure. We wish it understood that in this we do not lose sight of the active specific agents that in beginnings and for periods afterward, and possibly to the end, stand in the relation of cause to effect; but these die out, are disposed of and leave sequences. These sequences are the variations in type in structure which may or may not pass away that we note; and these in this type are the real factors that keep in operation the new adjustment and the element of habit.

For instance, look to the hypertrophies, atrophies, hyperplasias, adventitious and heterogeneous changes in structure, and study the element of habit therein. Who has not observed the aches and pains; the functional activities, the recurrences, the lapses from apparent states of health to disorder after more or less continued experiences of disorder, and after the removal of apparent causes and conditions for the same; the radical therapeutics of the day and in

most instances the gradual and final reversion to the original state and condition of health? How many sensations, aches and pains we meet; the persistence of the menstrual flow and menses, when we know beyond doubt that the agents for these activities have been absolutely done away with? How often we see the gynesia after prolonged diseases become restored to conditions that the skilled sense of touch knows are within the domain of the normal or standard type, when, with some reasonably sufficient cause the swing back into the domain of the previous experience is so sudden and aggravated that the observer is non-plussed? Who is not familiar with the phenomena of heredity and the climacteric? These are all kindred and can not be interpreted or comprehended save but by the element of habit; and in the progression of disease during the active stages, the host of experiences and evidences that are readily reconcilable and can be intelligently explained are many, and correctly appreciated lead to safe therapeutics. Appreciating the element of habit in health and its possibility and processes in gynecic disease, and comprehending the entity to be a variation in type either in relation to energy, function or structure, one, two or all, and these as related to the *natura* of the organism affected, obedient to continuity and conservation, we are led in the solution of the problems presented, to the rules and principles of *atavism* or reversion to the original type.

4270 Delmar Boulevard.

## SOME MEDICO-LEGAL FEATURES OF THE SCHNEIDER CASE.

Read before the Medical Society of the District of Columbia, Oct. 10, 1894.

BY IRVING C. ROSSE, A.M., M.D., F.R.G.S.

WASHINGTON, D. C.

With the softening influence of time, which modifies all things, our minds are prone to assume the blank state so necessary for calmness of thought and dispassionate consideration that should always be brought to bear on all questions of forensic medicine. It is in this frame of mind, I trust, that we now approach the consideration of a case that was attended by much public excitement.

On Jan. 28, 1893, I visited the district jail, in company with Dr. Godding, of Washington, to examine into the mental condition of a young man under sentence of death for the murder of his wife. Certain features of this celebrated case, but more especially the lunacy inquiry, came within the unfortunate category of those prejudged by public sentiment, regardless of calm consideration of the attendant facts. But the question of guilt or innocence being no concern of mine, judgment may be suspended on this point. Whatever a culprit may be from the special pleader's point of view, to the physician a patient is only a patient whether he be saint or sinner, and the judicial aspect of such cases in no way concerns us, unless the medical facts relate to the law or tend to promote the ends of justice.

As far as I could ascertain the prisoner's antecedents he had led an irregular eccentric life, was addicted to the abuse of alcohol and tobacco, and was unhappy in his domestic relations. A near blood relative had died of spinal disease, another was hemiplegic, another had nystagmus, and the father was a senile dement, being insane before and at the time his son was begotten. The prisoner had a poor common school education and his family were Lutherans.

From the jail attendants and the physician it was learned that the prisoner had undergone a marked change in conduct; from being neat in his personal appearance he had become slovenly and filthy; his manner of talking, from being quick and sprightly, had become slow and hesitating; when addressed he would be apparently forgetful and have difficulty in concentrating his mind upon matters as to which

he was interrogated, and before answering would repeat part of the question in a stupid way after the manner of echolalia. He refused food for fear of poisoning, suffered from prolonged insomnia, talked incoherently, especially about a wonderful electrical machine he had invented; frequently yelled in the night that persons were entering his cell, throwing acid upon him, and making attempts on his life.

I found on entering the cell a man of unkempt appearance with pallid complexion, long hair and beard and a morbidly suspicious manner. First inspection showed slender trunk and limbs and thin cigarette-stained fingers. He constantly and aimlessly picked and scratched his hands and wrists after the manner of many patients one sees in asylums. Palpation of the head gave no result, nor was there any marked peculiarity in its shape beyond a slight plagio-prosopia of the right side. There was a slight ptosis of the right eyelid, irregularity of the lower teeth, a narrow palate arch, and an extensive ranula. The superficial veins appeared healthy. There was a brown scar on the left of the glans penis. A quantity of urine passed in our presence showed a large excess of phosphates on analysis.

Various tests for the motility, sensibility, reflexes and special senses were applied. Exaggeration of the patellar tendon reflexes was present, and the prisoner either could not or would not distinguish colors. The circulation and respiration were weak. The pulse was 90 and irregular; the temperature under the tongue 99.5. Owing to the prisoner's stuporous condition and his morbid suspicion, it was a more difficult task to ascertain the limit of his ideas, imagination, will, and moral and affective sentiments. He complained of heat and pain in the back of his head and arms; of excessive itching of the skin; of inability to sleep because of the faces of dim green color on the walls, of whisperings and voices, and of the annoyance caused by persons throwing acid on him and having designs on his life. He also said that attempts were made to poison his food; he talked of the attempt to steal an electric invention, and accused his brother and mother of being inimical to him. When asked if there was anything he wanted he asked for medicine to make him sleep. Numerous questions put with a view to leading up to the prisoner's mental weak point failed to elicit much beyond the fact that his memory was apparently weakened, that he was suffering from phrenasthenia, and that he lacked the knowledge and shrewdness to dissimulate the systematized and fixed delusions which were ground out with hand-organ regularity at each visit. At one of these visits the prisoner showed not the slightest sign of emotion on the arrival of his mother, nor was there on several occasions any change in the beat or frequency of his pulse when suddenly asked about killing two people, one of whom was his wife, and that he was soon to be executed therefor.

With Dr. Godding and Dr. Brush, I did not think it possible for an ordinary ignorant man, even with special training in insanity, to feign successfully the symptoms observed. Malingering tests failed to lead the prisoner into any gross error, even after prolonged and varied conditions of examination.

In view of the foregoing facts and my wide experience with frauds and malingerers among thousands of soldiers, sailors, pensioners, and others, I felt satisfied that the prisoner bore the characters, physical and psycho-physical, of degeneration, of aberration, of constitutional abnormality sufficient for recognition, and I signified my willingness to go into court and testify as to the existence of paranoia. Besides, the symptoms observed were similar to the clinical picture of that affection as given by more than fifty authors whom I had previously consulted.

The inquiry accordingly came off before three judges, and on this occasion I had the honor to differ with my friend, Dr. Dana of New York, who was by far the most intelligent, conscientious and well informed of the experts employed by the adverse party.

The inquisitorial procedure conducted by the three judges was a long one; some twenty-nine witnesses being produced on either side, and the testimony was voluminous. To review it here at length would manifestly be out of place; but the legal procedure

adopted and the manner of getting medical evidence are open to damaging criticism, and do not strike the dispassionate observer as "being the wisest method of obtaining light upon the alleged insanity of the defendant."

At the outset of the inquiry, legal opposition suggestive of unfairness, was shown in the motion to exclude from the court the expert medical witnesses for the defense. After deliberation on the part of the judges, who were presumably without predilection and uninfluenced by the sentiment of the hour, this motion did not prevail. While the experts for the prosecution were given every opportunity and did cross-examine the experts for the defense, no such privilege of impeaching the skill and testing competency was allowed the defense, who submitted in writing eighty-four proposed questions which it was thought related to the facts in issue and tended to test the accuracy, veracity and credibility of a document alleged to give an enlightened report of the defendant's condition. Touching these questions, Chief Justice Bingham remarked, among his reasons for not permitting them to be asked: "It would seem to us that each and every one of them is in the nature of a critical, technical and rigorous cross-examination."

Not to comment at length upon the evidence adduced by the various witnesses, it was satisfactorily shown to many persons, among them members of the jury who tried the case in advance of the lunacy proceedings, that the weight of testimony bearing upon the prisoner's insanity was greatly on the side of the witnesses produced to prove the theory of his counsel; namely, "that the shock of the sentence of death, coming after the prolonged strain of the imprisonment for four months and the strain of the trial, acting upon a mind predisposed to disease, operated to dethrone his reason and render him insane, so that he is now unable to appreciate his present situation as a person condemned to death." Even the witnesses for the prosecution clearly established the existence of heredity, which is one of the only two factors that enter into the causation of all cases of insanity. In fact, the neurotic antecedents were so well shown as to remove any doubts as to the defendant's mental condition had there been such, and on being recalled, I testified substantially to this at the conclusion of the hearing of the inexpert testimony. So well indeed, do the best modern authorities recognize the complementary relations to each other of heredity and stress in the causation of insanity that it is now spoken of in mathematical terms as a function of two variables; and one may as well deny the fact that twice two make four as to doubt the two-fold causes of insanity. Notwithstanding this, and the further fact that a considerable part of the testimony for the prisoner was addressed to the mental condition of his father and to the erratic conduct and abnormal behavior in early youth of the son, Judge Hagner, in delivering the opinion of the court, pointedly disregarded these facts and characterized "these statements as comparatively unimportant."

In the course of the inquiry many questions, the purpose of which seemed irrelevant, were put by the prosecution in regard to the use of tobacco, and a sphygmographic tracing of the prisoner's pulse was introduced. The question of consumption of tobacco may be dismissed as immaterial and insignificant, since it was proved that the prisoner never used more than a quarter of a pound a week, and when the

supply was entirely cut off he improved in appearance and in the readiness with which he replied to questions. The inference to be drawn from such improvement is manifestly against the theory of feigning. A simulator would attempt to retain as far as possible the state which he had manifested during the medical examination and during his presence in court. While the nervous system of many persons is seriously affected by tobacco, many old and inveterate users have never been affected. A letter in my possession from a gentleman of 84 years, said to be one of the most inveterate users of the weed to be found in the whole State of Virginia, shows an absence of tremor and a clearness that would do credit to a school boy. While the examination was in progress I produced a sphygmographic tracing, and on asking one of the physicians employed to assist the court, whether the tracing in question was that of a man or some lower order of animal it elicited the reply: "I don't know." It was further asked: "Assuming the tracing to be that of a man's pulse, does he or does he not smoke or use tobacco?" To this the same reply was made, when I stated that the tracing was one of my own pulse and that I did not use tobacco. In defense it was testified that in the diagnosis of insanity the sphygmograph is of no absolute significance; that it is a mere scientific toy, and that any results obtainable from it may be ranked among the probabilities of science. Equally worthless was the testimony regarding the drawings, tracings, and the civil service examination papers introduced to show the work done and the employment of the defendant. As documentary evidence they showed a lower order of merit than is often found among idiots and insane, many of whom do creditable work as artists.

The inference to be drawn from civil service examination is, to say the least, extremely problematical. An instance has come to my knowledge in Washington of a contest in which among the applicants examined were a recent graduate of the United States Naval Academy and a person just from a lunatic asylum. On awarding the results of the examination the lunatic was recommended for the prize. As is usual in such cases, the presentation of the medical evidence proved unsatisfactory, more from the manner in which it was obtained than from the inherent difficulty of the case. Each counsel striving to make the testimony aid his own side thereby forcibly impressed upon it a blurred and distorted character, and each took just what suited his purpose. Concerning the report of the "three physicians of known eminence" employed to assist the court in the examination, a prominent member of the Washington bar, who was a disinterested spectator, on hearing it read remarked: "That document is more like a special pleader's brief than the expression of expert opinion." Since the makers of the report were presumably honest, though mistaken, I will not say that I share this sentiment as to its unilateral character, although some points of the report call for comment and criticism.

Among many irrelevant and immaterial statements, which could not be construed as evidence of either sound or unsound mind, independently of other matters connected with this case, the medical assessors, delegated by the judiciary, described quite truthfully the defendant's condition when they say that: "During our examinations he manifested a stuporous

apathetic condition and a vacuity of mind such as occurs in certain long standing insanities under other conditions." He "avoided the eye of the observer;" was "apparently oblivious to the presence of any one;" . . . "his general attitude one of suspicion;" . . . "his irrelevant and illogical (inconsistent) manner;" his "stupid behavior and far-away look." We are also told that they were not able to surprise the defendant in any way out of the constant expression of his delusive ideas; for the report indicates that on recovering from the effects of ether he "at once took up his complaint of alleged persecution and delusions;" "said he was being starved and called upon his mother to bring his food." The probative force of such facts go to show that the defendant could not keep up his feigning in such circumstances; but it requires greater acumen, on the part of any medical man who has ever seen a patient anesthetized, to see the significance or relevancy of the statements that "when he was given nitrous-oxid gas and ether he exerted an extreme amount of muscular vigor," that he "took ether evincing much cunning in holding his breath and suddenly turning his head." Further occasion may be taken to mention in terms of strongest condemnation this method of obtaining knowledge. The best authorities are against using alcohol, ether or any anesthetic or intoxicating drug for the purpose of obtaining an avowal from a supposed simulator. The expert has never the right, in order to insure his diagnosis, to impose suffering on any individual intrusted to his care or to put him in danger. By doing so he assumes the rôle of judge and inquisitor, instead of confining himself to his proper function. The well-equipped expert has enough means at his disposal to obtain exact knowledge without recourse to barbaric and dangerous proceedings which morality and contemporary science unite in condemning with the same severity as the conduct of a judge who would re-introduce the ancient procedures of the rack and thumb-screw.

If the use of anesthesia was of any probative value in this case, the proof furnished thereby was rather in favor of the defendant. A short time after the first test of this kind, I found him smelling strongly of ether; he had an excoriation on the end of his nose, and he showed a degree of exhilaration and rationality that I had not seen before. Like the improvement noted after withdrawing the prisoner's supply of tobacco, it is difficult to reconcile this fact with the theory of feigning.

We are further told in the report that the "fixed systematized delusions, which have been prominent here, are evolved out of preceding stages of insanity . . . requiring many months and years for development," and further, "we do not believe that from the manifestations testified to, a diagnosis of that form of insanity known as paranoia of Krafft-Ebing and his followers is possible." This statement utterly ignores all the prisoner's neurotic antecedents, the erratic conduct, abnormal behavior, and even insane conduct, which were testified to by numerous witnesses, among them several for the prosecution. To use the language of the court: "With one accord all these witnesses agree that from his earliest youth, preëminent over all his other vices was his addiction to falsehood; that his whole talk was a gasconade of impossible exploits and ridiculous lies."

Dr. Beatty testifies to the belief that the prisoner was crazy when he first saw him in jail, while Dr. Walsh, who had known him a long time, testified as to his general reputation for "being off and peculiar as a youth," and expressed belief in his mental unsoundness.

The family clergyman spoke of him as a person under "a long standing mental cloud;" another witness as a "dime novel hero;" another, of his impulsive and reckless actions and want of reflection; another, of his being different from other young men, an untutored child of nature, and of his moral depravity. One witness called him insane, a fool, an idiot and an arrant coward; another spoke of "grandeur and falseness as the general character of his talk;" while the jail matron testified to his extravagant statements as to the horses he owned, and to his electric invention, and excited manner.

Witness Paine said that the prisoner talked of his inventions and machine the first day in jail and frequently sat up all night. Witness Woodward, that the delusion as to the patent was noticed by him "along in the fall and last three months," and that a gradual change has come over the prisoner, who was torpid and sleepless. Russ, a prison attendant, that he noticed oddity in the prisoner before his wife died, also a change after conviction, and the persistency of the alleged insane manifestations. Peacock, that in July he talked quickly, that lately he talked slowly, etc., all of which manifestations show the forerunners of the prisoner's mental condition and make it quite possible to diagnosticate paranoia. Aside from the gradual development of the manifestations testified to, the medical advisers of the court totally ignored or were ignorant of the distinction of the best authorities between acute primary and chronic secondary paranoia, and they inadvertently spoke of this form of insanity as that of "Krafft-Ebing and his followers," when in reality some twenty-five authors before his time have written of this form of mental degeneration as far back as Vogel in 1764. Moreover, Westphal described the *acute* form as characterized by the sudden explosion of hallucinations, especially of hearing. In this case delusive transformations of hearing were one of the features; but as we cannot, except in an effective way, get into another person's brain to see his mind-stuff and hear what he does, it is scarcely possible to testify in a court with any degree of accuracy as to the existence or non-existence of such hallucinations. However, it is well known to persons skilled in penal matters that among convicts becoming insane, hallucinations of hearing and delirium of persecution are common forms of insane manifestation.

Another point in this case is that the emotional condition of the patient appears to have been ignored by the experts for the prosecution. It is contrary to all experience that a sane man, fully cognizant of his surroundings and of all that is going on about him, and who is feigning insanity, can control his emotional nature and prevent an increase of pulse under circumstances that would cause increase in any sane person. On this point the report says: "As to the importance attached to the condition of the pulse and the behavior of the individual when startling evidence is introduced in his presence, or when he was reminded of his position, we would say that we attach very little weight to variations in pulse as a test for the examination of feigned insanity, and

in making this statement we believe that we are in accord with all modern authorities."

In the first place this statement is inconsistent with the introduction into the court of a sphygmographic tracing to show the condition of the prisoner's pulse; then the pulsatile phenomena of different regions of the body have been known to furnish infallible indications since the time of Galen; and in the earlier days of American medicine, a resort to the state of the circulation was regarded so much of a crucial experiment in determining the proposition whether a man be or be not laboring under mental alienation, that of two men condemned to death in 1794, one of them alleged to be feigning was declared insane after medical inspection; the pulse test placing insanity beyond the possibility of a doubt on comparing the pulse of the insane victim with that of his sane comrade. On the strength of this representation by the medical commission the prisoner was respited and subsequently pardoned by General Washington.<sup>1</sup>

As to the third assertion of the court's advisers, that of their being in accord with all modern authorities, such is not the fact. On the contrary, after examining several hundred of the more modern authorities bearing on this subject, I find that scarcely any fact of modern clinical research is better established than the demonstrable changes in the pulse following transient changes in the central nervous system, such as that contributed by the play of mental or emotional activity, and that this motility of the state of muscular contraction of the arteries is so constant in persons of vigorous health that its absence is considered a sign of diagnostic value.<sup>2</sup>

The number of physical and psychical influences that can be clinically and experimentally shown to cause variation of the pulse could be mentioned at great length. Who has not experienced increased pulsation of his heart on meeting some familiar friend? Every practitioner knows that his presence hastens the pulse of his patients, especially that of women, children and nervous persons. Brain work, calculation, music and sensorial excitations generally accelerate the pulse, while different emotions give to it a vivacity sometimes very remarkable. After an excess of anger the pulse has been noticed to go up to 108. According to some authorities, pain makes it go up to 86 and 100 pulsations in a minute. A series of observations on medical students has obtained 120, 124, 128, 130, 134 beats a few minutes before examination. The influence of the generative function over the circulation, recognized by Galen, when he discovered by the pulse the malady of Justa, wife of the Consul Boëce, and who had a passion for Pylades, is just as potent to-day as it was a thousand years ago.

That the pulse varies in mental alienation according to the kind of insanity is therefore a well-established fact; and how three intelligent men could certify to a prisoner's being cognizant of all that was going on and listening to testimony the most damaging to his case without a momentary effect on his pulse is beyond all comprehension.

Other minor and irrelevant points touched upon by these "three physicians of known eminence" might be discussed at great length; but it suffices to notice that they report "no evidences of any external

structural alteration," and "nothing whatever abnormal was noted physically." Although they mention having found "the head small and an elevated palatal arch such as is frequently found in ordinary neurotic individuals and certain habitual criminals and the tongue pointed to the left side," yet we are not shown how such facts bear upon the correlation between anatomic structure and crime. In making this "exhaustive" examination bearing upon the organicity of crime, its anatomic nature, and degenerative source, why did they not find, or if they did why fail to report, a metopic cranium, facial asymmetry, ptosis of the right eyelid, an extensive ranula, irregularity of the inferior dental arch, dullness over the base of the right lung, and a scar on the penis?

In their general conclusions the report says: "There seem to have been no serious physical changes whatever in his condition;" "an absence of physical deterioration;" "no corresponding appearance of physical deterioration of any kind."

Let us see how the *post-mortem* corroborates the pathologic notions of the "three physicians of known eminence."

Shortly after the execution, the necropsy was conducted in Baltimore by a well-known Washington pathologist and myself. We found the usual cadaveric rigidity in a poorly developed body somewhat emaciated. There was no evidence of seminal emission that sometimes occurs after hanging. But little hemorrhage followed the incision. The brain on removal was dryer than usual, the pia was sticky, and there were minute patches of opacity on the left side. The veins were moderately full. The dura was not abnormally adherent. The right side showed the same stickiness with the minute patches. The left vertebral artery was double the size of the right, and both posterior communicating arteries were larger than usual. There was no sign of disease of the vessels, although the base of the brain was slightly soft. The right motor oculi nerve was narrower than its fellow. The spinal substance was quite soft, possibly a *post-mortem* result. The fluid in the ventricles was slightly tinged with blood, but the ventricles were apparently normal. There was some hardening about the membrane not adherent to the cortex with osteophytes in the dura.

The normal quantity of fluid was found in the thoracic cavity. The lungs, slightly hypostatic and emphysematous, showed numerous pleuritic scars and adhesions with a tubercular deposit in the upper part of the right; but there was no pulmonary apoplexy such as is common to asphyxia.

In the pericardium was an abnormal quantity of fluid. The cardiac cavities were moderately filled with blood and the valves appeared normal, except the tricuspid, which was increased in size to the extent of readily admitting the tips of the four fingers. The left ventricle was thinner than usual and the right heart was subnormal. The spleen was soft, with prominent Malpighian bodies and a smooth capsule. The kidneys contained more blood than usual. The capsules, not readily removed, were more adherent than normal. The cortex was normal in width and thickness. Urate deposits the size of a large pea were found in the apices of the pyramids. In the bladder was found a half ounce of turbid urine, but the walls showed no evidence of disease. On the left side of the glans penis was a brownish scar. The

<sup>1</sup> American Journal Medical Science, Vol. VIII. 1844.

<sup>2</sup> Arch. für Anat. und Phys. 1883. Supplement pp. 17-19.

intestines contained little more than gas. The mesenteric glands were extensively diseased, being enlarged, gray and softened, probably from a deposit of tubercle. The liver was normal.

Microscopic examination of the brain gave but negative results. The same may, however, be said of the brains of many patients who have died of general paresis, while many of the alleged pathologic findings of histologists have been equally observed in the brain of a calf.

During the progress of this lunacy inquiry, much was heard from various sources declaring the case to be an exceptional one. The public, who by the way were excluded from the court, were informed: "This is the first case on record that a man's mental condition has been inquired into because it was claimed that he became insane after the sentence of death had been pronounced upon him;" while Judge Hagner, who delivered the opinion of the court, in speaking of the weight to be given to the three experts who testified on behalf of the prisoner, says: "They all admit the case presented here is exceptional." Both assertions are absolutely contrary to fact and this is easily proved. It is a matter of record that in 1794 two men were sentenced to be hanged for treason, and one of them it was thought feigned insanity, whereupon a commission consisting of Dr. Shippen, Dr. Griffin and Dr. Earle, appointed by General Washington to inquire into the man's mental condition, reported him to be insane. The condemned man was respited and after the popular clamor for his death had subsided was pardoned. A notable feature of the case was the pulse test, which it was said placed the condition beyond the possibility of a doubt, on comparing the pulse of the insane victim with that of his sane comrade.

Another case almost the counterpart of Schneider's occurred a year previously in France. A man having killed two people, his condition became such as to call for a medico-legal report on his mental state. The inquiry showed that the prisoner's derangement was in no way connected with the commission of his crime. He was subject to alterations of memory, which would be lost and recovered some hours afterward. His mind was most of the time in a profound torpor. He had fixed ideas, delirium of poisoning, and refused food. Coupled with these symptoms was the circumstance of neurotic antecedents, which warranted the diagnosis of that form of delusional insanity known as paranoia. Instead of the sentence of death being carried out, the prisoner was sent to an asylum.<sup>3</sup>

Newspapers are not supposed to be scientifically accurate, and lawyers may be pardoned for distorting medical knowledge with which they are imperfectly acquainted, but when a learned judge from the bench delivers an opinion with the sanctity attaching to a judicial document abounding in *scientific* quotations from the Bible and the classics, and yet misstates a fact in forming his conclusion, what is the proper remedy?

As one of the experts who testified for the prisoner, I regret to say that Judge Hagner was utterly mistaken. I absolutely deny that I have ever admitted that the case herewith presented is "an exceptional one and out of the range of ordinary experience," and I challenge any one to read the typewritten copy of my testimony on the occasion named and find

even the slightest intimation of the case being "altogether exceptional."

To conclude this unhappy affair it may be asked, Was the medical examination of the court's advisers "exhaustive, thorough and complete," as they claim in their report and supplemental report? Did they fully weigh all the circumstances of the case? Was the method of procedure the best suited to promote an inquiry not influenced by predilection or sentiment of the hour? And was or was not the final result judicial murder? The answer to these questions I leave to the calm and disinterested intelligence of thinking persons, many of whom may see in this case a striking instance of the bungling application of medical knowledge to legal purposes.

## INTESTINAL INDIGESTION.

BY A. P. BUCHMAN, A.M., M.D.

PROFESSOR OF PHYSIOLOGY AND CLINICAL MEDICINE, FORT WAYNE  
COLLEGE OF MEDICINE.  
FORT WAYNE, IND.

To treat of intestinal indigestion separately from gastric indigestion would seem almost impossible, since it can not well be conceived how the former can exist without being a sequence of the latter, as gastric indigestion invariably precedes intestinal indigestion and is therefore always a factor which mingles its phenomena with all that which follows in its wake.

If proteolysis is not finished in the stomach and duodenum, the substances which have not run the gamut of complete proteolytic disintegration must pass the remaining intestinal length untouched, or undergo putrefactive changes at the instance of bacteria which provide the necessary elements, and hence, abnormal and deleterious substances arise which to a greater or less extent furnish fuel for general systematic disturbances. Intestinal putrefaction is then in its incipient stages, not due to a pathologic condition of the tube below the stomach and duodenum, but is dependent solely upon errors of gastric and pyloric digestive processes.

When any quantity, however small, of proteid substances escapes gastric digestion and also the action of the trypsin enzyme, they are at once attacked by certain bacteria which through putrefactive processes change them into aromatic bodies, viz., indol, skatol, skatol-carbonic acid and phenol. Excess of food ingested will universally induce such putrefactive processes which in infancy and childhood is exhibited in the bowel diseases of early life, and can, with reasonable certainty be differentiated from deflections by other causes, by the odor and appearance of the dejecta.

In adult life, the subjective symptoms are available and form a most interesting chapter of complaints which are mostly dismissed after being labeled with the hackneyed term, "biliousness," whatever that may mean. A coated tongue, a sluggish mind, a headache, a restless night, a treacherous memory, a hot, feverish, thirsty stomach, a bitter taste, a want of appetite, a fit of constipation, are symptoms which usually subject the liver, a very innocent but terribly abused organ, to a course of merciless therapeutic flagellation. In the light of our present knowledge of the functions of the liver it would be wise, I think, to float out our therapeutic craft in waters where deep sea soundings are more familiar. Its chemico-physiologic work is to a very great extent masked to us as yet, except as by infer-

ence when we analyze its by-product, the bile, and note the offices performed by its several constituents. This phase of intestinal indigestion which, as I have said, is due to the primary action of certain bacteria on albumen and albuminoid substances which have slipped past the duodenal gateway without receiving the vito-chemic touch necessary to render them innocuous is intermittent and transient, and of little consequence until by constant repetition it becomes a menace to the general organism. The toxic elements generated in this process sooner or later render glandular and cell environments of the intestinal tube altogether unhealthful. The air they breathe, the water they drink, and the food they eat, are charged with a miasm which absolutely forbids a healthy reaction, hence most complicated and decidedly serious pathologic conditions arise. The final or end products of primary bacterial action on the proteid substances are carbon dioxid, water, ammonia, nitrites, hydrogen and sulphuretted hydrogen. All taken together are really abnormal products in contact with tissues which will, for a time, resist their deleterious influence, but finally are compelled to succumb.

Another, and indeed the chief source of intestinal indigestion arises from the inability of the tube below the pylorus to successfully cope with the relatively enormous quantities of carbo-hydrates and hydrocarbons that are daily and continually ingested. The argument has been made from almost every conceivable view point except, as a matter of course, from the true and logical one, that man is or should be a vegetable and fruit eating animal. Just a little thought and attention will enable you to discover that every such argument is based on pure sentimentality. I venture the assertion that our evolution has not yet carried us to that point of ideal construction where we can live continuously on vegetable foods and fruits without placing our health in constant jeopardy. It will only be necessary for me to refer you to the arrangement of the teeth in the human subject and invite a comparison with vegetable and meat eating animals; then the fact that the stomach is almost wholly engaged in digesting lean meats, and similar substances, so utterly rules the whole controversy out of court as to render further reference to it wholly gratuitous. The structural arrangement of the small intestine from the pyloric to the ileo-cecal valve exhibits a degree of sameness, which is indicative of the fact that if the normal wants of the system were alone supplied, and the sense of taste was not intemperately gratified, its work would be relatively simple. The muscularis of the intestinal tube like the heart and all the involuntary muscle structures is of mesoblastic origin and is energized and controlled by the ganglionic nervous system, hence, when digestive errors become chronic and ensuing pathologic changes take place, similar structures throughout the whole organism suffer, first in sympathy, then after awhile take on a community of degenerative changes which are traceable to this single point of deflection. Perfectly normal intestinal digestion demands a perfectly normal anatomic apparatus with an unimpeded physiology. The downward peristaltic action must be continuous and just sufficient to keep the contents in constant motion. The *valvulae conniventes*, glands and villi, must be perfect in structure and arrangement so that they shall offer a normal resistance to the movement of

material through the tube. The normal stimulating substances within the tube will induce a flow of intestinal juice just sufficient to change and convert such substances into absorbable material; thus alternating periods of rest and activity which go together to make up a cycle of digestion will proceed absolutely without a sign or note to indicate the character of the labor being performed. In fact, a sensation other than the consciousness that the body is at ease and the mind is active, is a signal carrying with it a warning which, if intelligently interpreted would be efficient in avoiding a host of complicated diseased conditions.

Starches, fats, fruits, and sugars, do not excite fully, in fact only feebly, the flow of digestive juice in the stomach; the gastric fluid has no action whatever on this class of foods other than to assist in reducing them to a partial fluid. When the stomach contents have been made fluidic, the pyloric valve relaxes and the small intestine receives the material; it is stimulated and at once begins to pour out its secretion which becomes more and more abundant, increasing in amount up to the sixth or seventh hour of digestion. The whole mucous membrane becomes injected, and with the drops of mucus that are excreted we find an abundance of exudative epithelium. An abnormal amount and kind of intestinal fluid can be provoked by over-stimulation. Let there be constantly present an over-quantity of acetic acid and the result is an over-secretion of intestinal juice. This acid has the power to keep the mucous lining constantly injected and to keep the secreting cells working perpetually. This factor alone is sufficient to induce an intestinal catarrh. The acid is a fermentation product which in normal digestion is not present as an excess. This and other acid formations are in excess when the sodium carbonate, a constituent of the intestinal juice, is insufficient to completely neutralize them at the point when absorption is about to take place. While it is true that the contents of the small intestine are necessarily acid, it is nevertheless important that they shall not be excessively so. The pancreatic diastatic enzyme will form maltose, but is unable to further reduce this complex body. The burden is shifted to the maltose-converting enzyme of the intestinal wall, at which point failure to render it into the simpler monosaccharides, results in the formation of ethylic alcohol which by the action of mycoderma is converted into acetic acid. I have referred to this as one of the sources of excessive formation of acetic acid in the small intestine. Another very important source is when over-quantities of starchy foods are taken. Many of the starch granules pass into the small intestine with the cellulose covering intact. They attract to their interior a molecule or two of water which furnishes the full complement for chemic disintegration. The resulting products are alcohol, acetic acid, carbonic acid gas, and vinegar plant. Finally the carbonic acid gas bursts the covering membrane of the starch granule and sets free the contents. These act as irritants to the intestinal mucous membrane, keep it constantly over-supplied with blood, which by and by results in thickening of the mucous membrane, interstitial exudate deposits in the commencement of the lymphatics, paralysis of the intestinal villi, finally the submucous connective tissue structure is infiltrated and thickened, and the whole muscular structure undergoes vital changes. The inferior

ganglia of the solar plexus becomes paretic, hence a constant production of intestinal juice which is impoverished in the elements which possess digestive potency—it consists almost wholly of water and a viscid sticky mucus; and now we are in the presence of what, in my opinion may aptly be termed the completion of the first stage of chronic intestinal indigestion. When the villi are paralyzed in consequence of their constantly being bathed in carbonic acid gas, a product largely resulting from the destructive fermentation of both the carbo-hydrates and hydrocarbons, they lose their power to consciously select such food elements as have already been prepared for passage into the general circulation and readily accept everything that they happen to come in contact with, thus rapidly vitiating the general blood stream. The peristaltic movement is inhibited and after a time is completely paralyzed, when the constipation which is universally an accompaniment of this stage of intestinal indigestion ensues, bringing with it, its concomitant train of effects. This stage of the disease may and often does, last for many years, rendering the patient more or less an invalid all that time.

The second stage of intestinal indigestion presents quite a different, and altogether a much more serious pathologic picture. The whole lining membrane of the intestine is now thoroughly catarrhal, its epithelial investment is no longer capable of performing its allotted work with any sort of regularity and normality. The villi are practically paralyzed and entirely cease selective absorption; the whole glandular structure is undergoing degenerative and thickening processes, the ileo-cecal valve is paralyzed, the cecal end of the colon now fails in its peristaltic movements, the valvular opening to the appendix is permanently relaxed, admitting into the tube whatever may be in the vicinity of its mouth, hence the frequency of appendicitis. The colon becomes thickened throughout its entire structure, the colonic valves become lengthened and thickened. Alternating constipation and diarrhea are symptomatic conditions which to a greater or less extent are always present. The abdomen is now constantly tympanitic since digestion proper is greatly enfeebled and the abnormal fermentation processes have full sway. The spurts of diarrhea are characterized by large, yeasty, foamy, gaseous discharges, generally preceded by a sharp cutting pain. The diarrhea generally lasts for one, or at most two or three days, when it is again succeeded by a fit of constipation. The danger of stercoræmia is now past as it belongs to the constipation which is so prominent a factor in the second stage of the disease. Other and decidedly serious complications will arise during the second stage of intestinal indigestion which can only be here referred to in a general way; however, the tracing is clear and distinct and without a doubt the pathologic conditions which express themselves under many and divers names have their origin and etiology in the host of digestive errors which follow in the wake of this stage of the disease.

There is no way by which a distinct line can be drawn between the first and second stages of intestinal indigestion, as in many cases the conditions overlap each other. We find at times severe and obstinate constipation in company with well advanced pathologic expressions of the second stage, or again, we find easily provoked diarrheal attacks early in the first stage. The transmitted constitution and the en-

vironments will largely control the way in which the diseased conditions express themselves. Probably the most prominent disease which I believe, independent of heredity, depends upon wrong digestion and mal-assimilation, is consumption of the lungs. Through the vitiated blood stream all the organs of the body are badly nourished; the soil, so to speak, is prepared for tubercular and fibrous degeneration; a slight cold, over-fatigue, or any other depressing influence now acts as a precipitant, and the disease is established. Consumption of the kidneys, so-called Bright's disease, in its various forms depends upon an antecedent constitutional error. The nervous system is the chief sufferer, and very early in the course of the disease begins to resent its environments by phenomena which should be, in fact are, symptoms which very clearly point to the continuity of causation and uniformity of the general law which induces them. The diversities noted in disease of the nervous system are simply diversities of operation and when traced by the law of synthesis will as certainly lead up and back to the digestive system as the needle points to the pole. The much written of, but poorly understood condition that now masks under the appellation of neurasthenia, will yield up its scepter quite readily when attacked intelligently and persistently from the ground where digestive errors exist. I think it is indeed quite safe to assume that in every case of so-called neurasthenia, the stomach was the first to indicate a sense of systemic inharmony; following this in logical sequence came auto-infection which readily accounts for the mental and other phenomena which characterize neurasthenia. The ataxys, cord and brain sclerosis, of whatever peculiar type they may be, are to me logical outcomes from this stage of intestinal indigestion. Probably the most convincing proof of this statement lies in the fact that a thorough course of treatment directed to the relief and betterment of the digestive system will, if properly conducted, dispel many of the acute symptoms in a few months. In *tabes dorsalis*, the pains and girdle sensations disappear, as I have said, in a few months; in fact, I have seen the knee jerk restored, the patient could stand on one foot with eyes closed, could walk backward, and in short was so much improved that he could negate every classical test.

The third stage of intestinal indigestion is so vast and so far reaching as to make it altogether out of the question for me to do more at this time than to simply call attention to the fact that in truth there are these three general divisions. These may again be subdivided and classified, but I hold that the most simple classification is the best, as so much refinement in the grouping of symptoms and factor classifications will surely lead to confusion, and possibly to much harm; that many will be led to the treatment of symptoms and to the neglect of the potent force which is the active power in their production.

In the third stage we have a large grouping of diseases which, when studied from this view point arrange themselves in most orderly sequence around their cause. They mainly consist in such forms of pathologic action as result in speedy dissolution, as for instance, hasty consumption of the lungs, the forms of Bright's disease that run a rapid and fatal course, and consumption of the mesenteric glands. Many if not all, the rapidly fatal diseases of the nervous system belong to this grouping. Another

form of expression is the reduction of the general systemic resisting power which so often is exhibited in attacks of acute affections. We find these patients accepting acute diseases readily and frequently dying without presenting, objectively, an adequate cause.

I think it may be taken as a statement of fact, that if the whole digestive system was made a matter of careful consideration, its relation to every organ in the body intelligently worked out, its needs and normal wants alone administered to, the existence of disease could be minimized and such as did exist could be scientifically and intelligently treated.

I have purposely omitted in this paper, except a bare hint, all that pertains to the offices of the colon. In this, the field of possibilities is so extensive, there is so much to say, that any attempt to include it in a single paper would result in a dwarfing of the whole subject. I simply wish to add, in conclusion, that any form of treatment instituted for the relief and cure of intestinal indigestion must necessarily include a careful consideration of the stomach and colon; very little if any amelioration of symptoms will result unless they are both rationally included. The colon is within easy reach *via* the rectum, and it has been my experience that colonic baths properly medicated are immensely useful in the general treatment and care of patients suffering with intestinal indigestion.

### A CASE OF FRACTURE OF THE THYROID CARTILAGE—RECOVERY WITHOUT TRACHEOTOMY.

BY THOMAS B. EASTMAN, A.B., M.D.  
INDIANAPOLIS, IND.

Of the thirty cases of fracture of the thyroid cartilage reported by Durham, but ten of these recovered and most of them after a tracheotomy. Indeed, most authorities unqualifiedly condemn any delay in operating, Cohen saying: "Unless forestalled by precautionary tracheotomy and insertion of a tube, suffocative phenomena may intervene at any time from edema, displacement of fragments, or occlusion of the caliber of the air tube with blood clots."<sup>1</sup> He further says, "better far that an unnecessary tracheotomy should occasionally be performed without detriment to the patient than that a number of cases should be allowed to terminate fatally for the want of it."

Stimson says:<sup>2</sup> "It is not safe to wait until it (dyspnea) has become extreme, for its increase at the last is often so rapid and so sudden that death takes place before relief can be given. It is therefore the part of prudence to interfere early and before the interference is made actually necessary by the defective breathing."

Hunt<sup>3</sup> recommends tracheotomy when bloody expectoration or emphysema accompanies the other symptoms. Hamilton, however, counsels waiting until respiration is seriously interfered with. I desire to report a case of undoubted fracture of the thyroid cartilage recovering without tracheotomy, and thus add one case to the limited number which have recovered without operative interference.

At no time during the first few days was I certain that an operation would not prove necessary, yet I was determined not to interfere until it was demanded by symptoms graver than were at any time present. I believe that the result justifies my course.

On Dec. 14, 1894, Mr. K., aged 38, foreman in a foundry, was struck in the "throat" by a heavy piece of timber hurled from a buzz-saw at which he was working. The timber also cut a gash in his chin which had been sewed up previous to my first examination, some six hours after the accident, when I found him with a temperature of 99.6, pulse 86, respiration 24. There was almost complete aphonia, dyspnea and cough which gave the patient excruciating pain. At each paroxysm of coughing he ejected bloody mucus from the mouth. Dysphagia was complete, even an attempt at swallowing saliva giving him much pain. His face was livid. The skin was discolored and the tissues about the larynx much swollen. Inspection showed that the pomum Adami, rather prominent before the accident, was wellnigh obliterated, and that the thyroid cartilage was displaced to the right. Manipulation showed abnormal mobility and on pressure inward the patient made me understand that he felt something stick him. A diagnosis of fracture of the thyroid cartilage was made. As nearly as could be determined by manipulation, the line of fracture extended from the highest point of the upper margin of the right ala of the thyroid cartilage in an almost straight line downward to the crico-thyroid membrane. In spite of the other grave symptoms the respiratory function was fairly well maintained, and on the strength of this symptom I decided to await developments. No attempt was made to restore the normal relation of the parts. Antiphlogistic measures were resorted to, believing that if the inflammation was kept within bounds much would be accomplished. A Fothergill poultice was ordered placed over the seat of injury together with morphia sulphate gr.  $\frac{1}{2}$ , by the rectum, to be repeated as often as necessary to subdue the pain. On the morning of the second day he was able to take a little nourishment by throwing his head back and allowing broth to run down his gullet, but any exercise of the muscles of deglutition still caused him great pain. In this way he was fed for four days. For five days he was unable to speak above a whisper, and at this time (twenty-four days after the accident), his voice is still impaired and the larynx much displaced to the right. There is still abnormal mobility of the right ala of the cartilage.

Dr. G. V. Woolen, Professor of Rhinology and Laryngology, Central College of Physicians and Surgeons, of this city, saw the case on the seventh day after the accident, and I herewith append his report:

Dr. Thomas B. Eastman brought Mr. K. to my office for special laryngoscopic examination, with statement that patient had received a stroke from piece of flying wood across larynx, followed by violent inflammation, aphonia, hemoptysis, etc. There was yet remaining a distinct depression in a perpendicular direction across the right wing of the thyroid cartilage with mobility from pressure. Internally there was found considerable congestion of larynx, especially of region of right cord and ventricular band, both of which bulged into cavity of larynx and met opposite parts prematurely in efforts at phonation.

## A FEW REMARKS ON THE EARLY HISTORY OF RECTAL DISEASES.

Read before the Mississippi Valley Medical Society, Hot Springs, Ark.,  
Nov. 3, 1894.

BY S. G. GANT, M.D.  
KANSAS CITY, MO.

In the selection of historic medicine for my subject, I am well aware that I have chosen one that is rarely touched upon in medical societies and the current literature of the day. The study of the history and progress of medicine has ever been of great interest to me. I well remember, when holding down the benches at college, how the class used to enjoy a brief change from our routine lectures, when one of the professors would tell us about the heroes of medicine hundreds of years ago, and how such men as Hippocrates, Celsus, Galen, and others of the ancients, practiced the art and science of medicine; we listened attentively and marveled at their accuracy of diagnosis and the practical manner in which they effected a cure; this, too, with their meager knowledge of anatomy and physiology.

The science of medicine and surgery extends its inquiries over such a vast field, and comprehends such an enormous mass of facts and observations, that it would be impossible in a paper of this length to give more than a brief *resumé* of the history of one special department of medicine, which, I trust will be of some interest to this society, viz., that of rectal diseases.

I believe with that scholarly physician, William Bodenhamer, that there is no class of diseases within the whole range of medical literature which has a more ancient history, a more hoary antiquity, and a more conspicuous sacredness than some forms of rectal disease. In fact, the history of this class of diseases embraces all ages, including Hebraic, ancient and modern history. Medical men have, from the time of Adam down to the present day, devoted much time and study to these diseases. The first recorded mention of rectal diseases that we know of was made by Moses, the law-giver. This can be found in the fifth book of the old Bible. After explaining to the Jews the manner in which they would be rewarded if they strictly carried out the laws of God, he goes on to say: "And if thou wilt not hearken unto the voice of the Lord, and observe his commandment then all these curses shall come upon thee." He then records a number of curses; the only one of interest to us, however, is the following: "The Lord will smite thee with the botch of Egypt and with the emroids (hemorrhoids), whereof thou canst not be healed." Now, if we turn to 1. Samuel, v. 5, we find the following bit of interesting information: He tells us that the Philistines took the ark of the Lord from Ebenezer and brought it unto Ashdod, and forthwith the hand of the Lord was heavy against them, and He smote the men of the cities both small and great, and they had the emroids in their secret parts." Again, in Psalms LXXVIII, v. 66, we find recorded that He smote His enemies in the hinder parts. The ark of the Lord was then removed to Gath and Eckron with the hope that the plague, (emroids) would be removed, but such was not the case; on the contrary, these cities were alike afflicted. The people then began to seek a way in which they might rid themselves of their afflictions, and to this end they sought out the priests, and inquired what they must do to obtain relief. It is of interest to note the man-

ner in which the cure was effected. It appears that after consultation, the priests and divines told the people to return the ark of the Lord to the Israelites from whom they had taken it; but it must not be returned empty. They must make a trespass offering of five golden images of the "emroids," according to the number of the lords of the Philistines; "for one plague is on you all, and all your lords. Do this, and thou shalt be healed."

It is stated on good authority that the natives in the far East at the present time make images of their afflicted parts and offer them to their gods as a trespass offering, and believe that through them alone can they obtain relief, many of their places of worship being burdened with such offerings. From the fact that the Israelites were threatened with the plague previously referred to, some writers have argued that the Jews from then down to our time are more frequently afflicted with rectal diseases of a *hemorrhoidal* nature than any other race of people. They teach that this malady is inherited by the Israelites, and that it is entailed upon them and their posterity forever, because of spiritual disobedience. From my limited study of Hebraic and ancient history, together with my personal experience in the treatment of these diseases among all races, both in private and hospital practice, I have been unable to obtain any evidence to substantiate such a claim. On the contrary, I have had ample opportunity and have noted that the Jews are no more liable to be afflicted with rectal diseases than other people. Again, there is not a single instance in the Bible where it states that the Israelites ever had this threatened punishment inflicted upon them. On the other hand, there is abundant evidence to show that the plague with which the Jews were threatened was visited upon the Philistines some three hundred years thereafter, for stealing the ark. In view of the limited evidence at our command, I believe we are justified in concluding that the Jews are no more liable to be afflicted with any form of rectal disease as a result of divine punishment, than are the Gentiles. Unfortunately, we have no definite knowledge of the exact pathologic meaning of the Biblical term, "emroids," so frequently mentioned in the Scriptures. This is owing to the wide diversity of opinions of the Biblical commentators. Some took it to mean a disease similar to bleeding piles; others, that there was a prolapsus of the bowel which remained out until it became putrid and sloughed off; and others took it to be some form of dysentery, and not a few that it was of a fistulous nature. The Greeks, Hippocrates, Galen, and others, evidently thought it to be a diseased condition of the rectal veins, accompanied by hemorrhage, for they substituted the word hemorrhoids for the Scriptural one, "emroids." Ever since that time, hemorrhage from the rectum has been diagnosed as such. It would appear from the writings of the ancients that some thought the hemorrhage active; others, that it was passive. It seems that they never mentioned anything about swellings or protrusions. According to our more modern teaching, the term hemorrhoids is applied to almost any swelling about the anal region, no matter whether there be hemorrhage or not. It at once becomes evident then that this term, as used by the early writers, was a misnomer and did not express the exact pathologic condition present, only the most prominent symptom. Leaving the Hebraic

and turning to that of ancient history, we find frequent mention of certain forms of rectal diseases, also the plan of treatment adopted.

It is gratifying to note that in many instances the treatment suggested by the Greeks, Celsus, Hippocrates, Galen, and Rhazes and Abbas, the Arabian physicians and others of the ancients is practiced by the surgeons of our time with very slight modifications. This demonstrates the fact that they were not altogether wrong in their pathology though they were lacking in the knowledge of anatomy and physiology that we possess. I have neither the time or inclination to pay more than a passing glance at the treatment followed by the ancients in some of the more common forms of rectal diseases. Fissures were described as superficial erosions, cracks, or chaps, and, being slow to heal, the treatment consisted in converting them into recent ulcers by paring, scarifying, or incising them with the finger nail or scalpel when they were made to heal by topical applications. Hemorrhoids were ligated as to-day, except that the skin was not severed to prevent after-pain. Those who did not favor the ligature method used the cautery by puncturing the tumors, in addition to which various drugs were used locally. Fistula was accurately described by them and so far as I can find out their treatment consisted principally of setons and the local application of various drugs.

Many of the ancient writers believed that divine power must be enlisted in order that a cure might be effected in the various forms of rectal diseases. Others believed that an "amulet" was necessary; that to carry something in their pocket—a piece of metal, a precious stone, or a certain kind of nut or vegetable would cure them, and this practice is not abandoned to-day. For many of our own countrymen carry with them a buckeye or a horse-chestnut when suffering from piles or fistula, as an "amulet" for their relief or cure. Many patients have told me of remarkable cures effected in this way. The Irish potato comes next in favor to the buckeye, and it must be "dug out of the garden when the moon is right," put in the left trouser pocket, and is never to be removed under any circumstances. After a time they shrink up until they are no larger than a pigeon egg and are as hard as a rock. Then they will cure the worst case of piles. From the time of the Greek writers down to about the fifteenth century there is nothing recorded that would be of especial interest in this paper, but about this time or a century later, the writings about different diseases were very prolific and have continued so ever since. The reason given why the surgeons previous to this time said nothing about this class of diseases was because of the false delicacy in those who had them in not letting it be known. Again, in olden times most rectal diseases were considered incurable, and for a person to have an incurable disease was to have a disgraceful one; hence, these persons suffered on in silence lest they reveal their disgrace, and be ostracized by society. We find a very interesting instance of this in a treatise on "The Fistula of the Anus," originally written in Latin by John Astruc about 1715, the first individual work of the kind ever written, a copy of which I possess and value highly. He says, "of late years (about 1700) was a case of fistula scarce seen or heard of by the physicians of the last age. But when once Louis XIV., King of France, labored under this complaint it became fashionable,

and a vast multitude of these cases suddenly presented themselves, and after the King's example every one made an open and voluntary confession of this once secret disorder." He then records a parallel case, by Pliny, in the reign of Tiberius Cæsar; he says, "the cholic first showed itself, nor did one man in Rome ever complain of this disorder until the Emperor had been severely attacked by it." Fistula in ano has been immortalized by Shakespeare in his play "All's Well That Ends Well," based upon the King's having a fistula. This play is said to have been written in 1606. Again, the great historian, Hume, in writing of the death of King Henry V., who died about the year 1422, says he was seized with a fistula, a malady which the surgeons at that time had not the skill to cure. It is said that Louis XIV. deferred having an operation by the knife for many months though his attending surgeon, Monsieur Felix, insisted that such an operation was necessary if he anticipated a cure. As the laity became aware that their sovereign was suffering from a fistula many cures were suggested by physicians, priests, and others who claimed that they had effected many remarkable cures by their respective methods and who took this opportunity to gain His Majesty's favor. After deliberating he determined to give each one a chance to prove his assertions, but he was too long-headed to have the experiments tried on his own person. He set apart a wing in the palace and placed a number of his subjects in the various rooms who were suffering from fistula, and all of the various remedies suggested, together with a number of mineral waters said to always effect a cure in fistula cases, were given a trial. Not in a single instance was a cure effected. At last the King, to whom Monsieur Felix gave an account of the experiments, determined to have the operation performed. One morning when nothing of the kind was expected by the courtiers it was done, several incisions being made. This happened on Nov. 21, 1687. The cicatrization was well managed and the King perfectly cured. His Majesty royally recompensed Monsieur Felix and his assistants, the total amount of the fee being \$73,500. These were "royal days for surgeons," says a writer in the *Medical Chirurgical Review*. Immediately after the King's recovery this disease became fashionable and hundreds of people flocked to Monsieur Felix to be operated on for this complaint. It is even hinted that certain courtiers who previous to this time had concealed their afflictions, selected Versailles as the place to be operated on, for here the King would hear of their indisposition. One writer goes so far as to say that some of them did not have fistula at all, and were much put out when informed that an operation was not necessary.

My paper has now reached such a length that it would burden you, should I endeavor to even mention the various operations and methods of treatment that have been brought forward during the last four or five hundred years. The investigations of the various important diseases affecting the terminal portion of the colon, have during this time been prosecuted with very considerable ardor, and the advantages gained in consequence have been markedly progressive; for this knowledge we are indebted among others to such celebrated surgeons as Brodie, Allingham, Cooper, M. Boyer, Dupuyren, Van Buren, Bushe, Smith, Salmon, Curling, Ashton, Whitehead, Bodenhamer, Matthews, Kelsey, Cook and others, I was about to

omit the name of that ingenious surgeon, Calvert, whose tallow candle led to the idea of the treatment of stricture by bougies.

In concluding my paper, I wish to read a few verses from Erichsen's *Medical Rhymes* written by a patient while undergoing treatment for stricture. It is said he left them on his physician's desk just before taking his departure for Niagara Falls, "where the water runs down hill with nothing on earth to hinder it."

"When sorrow's cloud is cast athwart  
The sunshine of my mind,  
When I, with gloomy care distraught,  
No recreation find;  
When sighing o'er my helpless lot,  
And what I used to be,  
I'll seek some quiet, tranquil spot  
And pass a small bougie."

"Let strictures on my conduct pass:  
Unnoticed let them be;  
A stricture somewhere else, alas!  
Is more deplored by me.  
In hope this blight on manhood's bloom  
I yet effaced may see,  
I'll hie me to my quiet room  
And pass a small bougie."

In the preparation of this paper I have made frequent reference to the following works: Bodenhamer, on the Rectum and Anus, 1855. Anal Fissures, 1868, and Hemorrhoidal Diseases, 1884. Erichsen, on Medical Rhymes, 1884. Paul, of London, on Lower Bowel, 1869. John Astruc, on the Fistula of the Anus, in Latin originally, and translated into English by John Freke, F.R.S., London, in 1738.

## FIBROUS POLYPUS OF THE RECTUM.

Read before the Delaware County Medical Society.

BY G. W. H. KEMPER, M.D., AND HUGH A. COWING, M.D.  
MUNCIE, IND.

The specimen here presented is one of fibrous polypus recently removed from the rectum of a girl aged 6 years. At various times before the removal of the tumor, the child had passed slight quantities of bloody mucus, and the mother, at times, had noticed a fleshy mass presenting at the anal orifice. The father had applied to us for medicine for piles, but the exceeding rarity of hemorrhoids in children led us to suggest to him to bring her in for examination; and that it was probably a case of polypus. This was confirmed upon examination. The tumor was attached by a long slim pedicle to the rectal wall nearly an inch above the external sphincter. After the expulsion of a warm water enema the polypus came into full view, and its size and attachment determined. A ligature was thrown around it near its junction with the pedicle and the tumor was removed, there being but slight hemorrhage. The pedicle was restored to the rectum (without a ligature). Chloroform anesthesia was employed.

According to Parvin, polypus of the rectum is rare in the adult; still rarer in either adult or child is rectal fibrous polypus.

Gross refers to the uncommonness of polypi in the rectum, and divides them into two classes: "Gelatinous or adenoid, and fibrous"; the former being of far more frequent occurrence.

Allingham remarks that "polypi of the rectum are usually described as being of two kinds, the soft or follicular, and the hard or fibrous; the former being found in children and the latter in grown persons." He also states: "I quite concur in the statement that the soft polypus is the one always found in children, but I am of the opinion that the fibrous variety is rare, even in the adult." Subsequently he states that he does not remember meeting in his practice "with more than six distinctly fibrous polypi".

Dr. Parvin (Trans. Indiana State Medical Society,

1873, p. 113) in his interesting article on "Fibrous Polypus of the Rectum," gives the following history:

"Mrs. —, 42 years of age, a widow, states, that for nearly four years she has suffered from pain in the rectum, tenesmus, hemorrhages, and that for some months past the bowel has prolapsed whenever evacuated, requiring her to replace it. Besides—this is her narrative—the bowel comes forward into the vagina and presses against the urethra, causing frequent and sometimes difficult urination. Sitting for any length of time gives her great uneasiness while in a recumbent position she is comparatively comfortable. By medical advice she has used astrigent injections for the hemorrhage, which is supposed to result from piles. No examination, however, has been made. The patient lying on her back, with her limbs drawn up, digital examination of the vagina and then of the rectum determined the presence in the latter of a hard polypus, attached by a long thin pedicle to the anterior rectal wall, two inches above the anus. Immediately the tumor was brought outside of the rectum, a ligature applied to the pedicle and the latter divided below the point of ligation."

## A REPORT OF TWO CASES OF LEPROSY IN NATIVE-BORN CITIZENS OF OHIO.

BY J. G. McDOUGAL, M.D.

NEW LEXINGTON, OHIO.

On Dec. 19, 1894, there appeared before the New Lexington Board of Pension Examiners, Hannah M. Garey, an applicant for pension as a dependant child of George W. Garey, a deceased soldier of the One Hundred and Eighty-Seventh Regiment, Ohio Infantry. Examination disclosed that she was a victim of anesthetic leprosy, the following manifestations of which she presented: The left hand and distal third of fore-arm were swollen and rather firmly thickened, the hand and wrist being about twice the normal size. The distal phalanges of all the fingers were lost and the stumps healed. The thumb was slightly flexed, the nail deformed, thickened and discolored.

The hand was being amputated at the radio-carpal articulation by a narrow encircling ulcerative process and the work was so near completion that only the ulnar vessels and a few tendons attached the hand. Both surfaces were covered by granulations and bathed with extremely foul-smelling pus. The right hand and fingers were swollen and clubbed, the distal phalanges of all the fingers lost, and the thumb affected as the left.

Both feet were swollen to one and a half times normal size and the swelling also involved the lower third of legs. The first three toes of each foot were lost at middle of proximal phalanges and the little toes at distal joints. The remaining toes were clawed and the nails deformed. In the middle of left sole was a deep ulcer from which there was a very offensive discharge. All the affected members were decidedly anesthetic—the thermal anesthesia being especially marked. There was an anesthetic bleb, the size of a silver quarter, on outer side of right arm just above elbow. The tongue, lips and nose were scarred and somewhat deformed from ulcerations that had healed.

The subject of this description is 18 years of age and this malady began to manifest itself when she was fifteen months old. In two or three years the toes began to ulcerate and come off; and the hands became involved, the flesh ulcerating from the fingers leaving the blackened dry bones exposed and these she persistently drummed on the tables and chairs until her mother cut them off with shears. She menstruated regularly from the time she was 14 years of age until about one year ago when menses ceased. The drain from the amputating ulcer which

developed about eighteen months ago probably caused the cessation of the menstrual flow.

Learning that a sister 8 years of age had been similarly afflicted for three years I visited her, finding the following evidences of the same disease: Her feet are clubbed and legs stocky, and the skin covering them is thick and scaly and decidedly anesthetic. Two toes are lost from each foot. The hands are also thick and the skin covering them rough and anesthetic; the nails are growing deformed and dark.

The parents and grandparents of these leprous sisters were all natives of Ohio and belonged to long-lived families. The parents were married in 1866. There are eight children and all are healthy except Hannah M. the fourth born, and Hattie the last born.

The mother is 44 years old and healthy. The father was pensioned for sunstroke. He died from apoplexy March 10, 1893. The mother states that the only visible disease the father ever had was a skin eruption on end of nose and upper lip which gave off an offensive discharge. It developed a few years after their marriage and never healed. It must have been slight, as several acquaintances of whom I inquired had never noticed the affection. He had consulted physicians about it, however, who had called it eczema and had treated him for it.

The One Hundred and Eighty-Seventh Regiment, Ohio Infantry, of which the father was a member was stationed during the few months it was in service at Nashville, Tenn., Dalton, Kingston and Macon, Ga.

I am willing to submit without argument that the father was a leper, in whom the bacillus lepræ did not vigorously thrive; that leprosy was communicated to him while in the South during the war, and that he communicated the disease to two of his children.

## REFLEX IRRITATION AS A CAUSE OF DISEASE.

BY EDWIN WALKER, M.D.  
EVANSVILLE, IND.

Medicine has suffered from "fads" from time immemorial.

The authority of some great leader or teacher is enough to bolster up an error for a generation or more. In fact, much that is to-day taught is merely the dictum of some one who has never taken the pains to investigate the truth.

No error in modern times has held such tenacious hold on the professional mind as that of reflex irritation as a cause of nervous disease. To most of us the explanation of the occurrence of any nervous phenomenon or lesion is satisfactorily accounted for if some peripheral irritation is found; a long prepuce, some slight version, flexion or laceration of the uterus or other deviation from the picture in our charts, is sufficient to account for hysteria, epilepsy or other nervous disease. This, too, in spite of the fact that all these minor lesions are repeatedly met with unattended by any nervous manifestation, yes, even gross disease of genital or peripheral nerves is often if not generally unattended with serious nervous disease.

I have just had a patient, a lady of 35, who for four years has been attending to her household duties with an elongated, badly ulcerated cervix hanging between the thighs. She has no nervous symptoms whatever, and seeks relief from the trouble merely for the local inconvenience.

The theory has a few familiar conditions which seem to hold it up and are usually accepted as a full vindication—vomiting in pregnancy, and certain minor urinary difficulties from irritation from a long prepuce are some of these. A moment's reflection will show how little there is in these. They are merely slight exaggerations of physiologic reflexes and are not distinct nervous diseases. Because pregnancy causes vomiting in many cases, it does not in the least warrant the conclusion that continued irritation of the uterus will cause epilepsy, insanity or other definite nervous disease. On the contrary, a study of any of these will reveal deeper causes. We should always keep in mind that peripheral irritation does give rise to reflex symptoms, but that this does not prove that they cause definite systematic nervous diseases.

The reflex theory dates back many years. Early in this century, and perhaps still earlier, it was offered as an explanation for certain neurotic phenomena, but its prominence in the medical mind of to-day is due to the lectures of Brown-Sequard on the physiology and pathology of the nervous centers, delivered in London in 1858. In 1833 Stanley had written of urinary paraplegia (*Med. Chir. Trans.*, Vol. XVIII), but the prominence given to reflex irritation in these remarkable lectures gave it the impetus of authority which still sways the medical mind. If I had the time, I would like to read you some of the cases cited by the author, that you might see how far he went with this idea. For example, the extension of inflammation from one eye to the other, inflammation of the testicle due to passing calculi or ileo-sacral neuralgia, diseases of the urinary organs producing paraplegia, also paralysis from worms or other irritation of abdominal viscera are attributed to reflex irritation. He cites a case of peritonitis and death following operation on the cervix which he explains in the same way.

In most of these cases we know to-day better how to interpret the pathologic process, but at the same time the reflex theory was used as it now is to explain where our knowledge does not find anything better.

Following Brown-Sequard was I. Baker Brown with his work on "Curability of Certain Forms of Insanity, Epilepsy, Catalepsy and Hysteria in Females," 1866. In this work he claims that many cases of the diseases mentioned are due to irritation of the pudic nerve and especially to that branch distributed to the clitoris, and they were to be cured by excision of that organ. He reported eight cases of hysteria, seven of which were cured and one relieved by the operation.

In 1870, Sayre reported cases of urinary troubles of various kinds, as well as paralysis and other grave nervous diseases, due to adherent prepuce and these were promptly cured by breaking up adhesions or circumcision.

Otis, in 1874, published a paper in which he reports cases of paraplegia enuresis and vague nervous troubles cured by urethrotomy for stricture of the urethra. Since that time, although many of these claims have been proved fallacious, still we are constantly having contributions with reports of cures, all of the same vague and uncertain kind and by the removal often of slight peripheral lesions.

Two years ago, Robert T. Morris reported several similar cases cured by breaking adhesions of clitoris and prepuce. It is not necessary for me to remind

this audience of the uncertainty of conclusions drawn from the cure, or seeming cure, of any disease, but especially of neuroses. The chances for error and deception are familiar to all. Is there a physician here who has not encountered cases which he thought he had cured by some plan of treatment or operation, and later found that he was entirely mistaken and that the improvement was only transitory as is so common in all nervous diseases. For nearly twenty years I have thought much of this question, my attention being first called to it by the articles of Sayre. I followed his advice and did many circumcisions and later, mainly through the teachings of Emmet, did operations on the cervix and vagina, and have observed many cases of neuroses in women presenting various lesions of the genital tract, and I want to say here, that I have never seen a case of epilepsy, insanity, catalepsy, hysteria or grave neurasthenia, nor any organic disease of the nervous system, cured, or even permanently benefited by any operation on the genital tract, either done by myself or any one else. I have also noticed as I believe every one else has, that a large proportion of patients who consult us for diseases or injuries of the genital tract do not suffer from definite nervous disease, and on the other hand, that of patients who do consult us for nervous diseases, many and perhaps most of them are free from genital disease. It seems to me, therefore, that in a given case in which we find genital irritation and nervous disease, careful inquiry into the cause will develop other more potent causes. The same is true of irritation arising from abdominal viscera or other peripheral irritation. I have never, myself, had a case of nervous disease which I thought was due to peripheral irritation. In most of them other causes could be demonstrated. I want to be distinctly understood in this matter. I do not deny that lesions of the genital tract may not in some way derange the nervous system, but I do say that it does not do it by reflex action. For example, a woman has a bad laceration of the perineum, that interferes with her locomotion, it is difficult or painful for her to go about; her life becomes sedentary; she suffers with constipation, later dyspepsia from her inactivity; then her general system suffers from deficient nutrition as well as the want of healthful exercise. The nerves are not nourished and disease is engendered. Or a patient has some disease of the abdominal viscera, perhaps he has intestinal indigestion and nervous symptoms—a very common thing. Are we now to say that his nervous disease is reflected from the bowels? No, indeed. The lack of proper digestion and assimilation of food starves the system or by auto-infection poisons it. Here we will find the causes of more neuroses than all the peripheral irritation you can trump up. Auto-infection from poison generated in the intestinal canal or elsewhere, and starvation from mal-assimilation are the causes in most cases, and these should be looked into while repairing local lesions or injuries.

The repudiation of the widely accepted importance of reflex irritation, as a cause of disease, is by no means original with me nor is it new. Gull, in 1856, protested against it. (Med. Chir. Trans.) Jaccoud followed in the same vein in 1864. Romberg, Hussmann, Leyden, Weir-Mitchell and Goodell have pointed out some of its errors. Skene, in his work on "Gynecology," devotes a chapter to gynecology as related to insanity of women, that should be care-

fully read. Landon Carter Gray (Archives Anat. and Surg.) in 1882 published an able and comprehensive article on this error, and in his recent work devotes a chapter to it.

I have tried briefly to direct your attention to what I consider a great error, and I believe you will find in the future that in any case where you are inclined to attribute the cause of any disease to reflex irritation, a careful study will reveal other more important etiologic factors.

## ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 125.)

### CHAPTER III.

*Case 7.*—Yellow fever; severe case; jaundice; albumen in urine; recovery. Wm. Busse; age 25; native of Germany. Has been in New Orleans seven months, and came here from Red River. Seized with pain in the head and back and fever on Oct. 11, 1873, and entered Charity Hospital, Ward 24, October 13. At time of admission, complained of pain in head, back and knees. Tongue red at tip and edges and coated in the center. October 14, conjunctiva of eyes congested and yellow; surface of body yellow; nausea and vomiting; breath and odor of body foul; urine abundant and contains albumen and casts. On October 15 and 16, pulse intermittent, but the patient improving. On October 20, the patient was able to sit up and to be brought down to my clinical lecture in the amphitheater, and on October 22 was able to walk about the hospital. After the complete establishment of convalescence the patient was confined for several weeks by a painful abscess in the axilla. The following observations were made on the pulse, respiration and temperature:

Date.	Pulse.		Resp.		Temp.	
	M.	E.	M.	E.	M.	E.
1873						
Oct. 14	84	90	32	36	103.4°	103.8°
" 15	80	86	24	26	100.2°	102 °
" 16	82	84	26	24	100 °	100.2°
" 17	84	86	26	30	101 °	101.8°
" 18	82	78	26	24	99.6°	99.2°
" 19	80	82	22	24	99 °	100 °
" 20	84	84	26	24	98.6°	98 °
" 21	88	92	24	24	100 °	101 °
" 22	78	96	30	22	98.2°	99.8°
" 23	82	84	22	24	100.4°	100.4°
" 24	80	82	20	18	98.4°	99.3°
" 25	80	...	20	...	99.7°	...
" 26	80	...	26	...	98.8°	...

*Case 8.*—Yellow fever. Edward Ryan; age 42; native of Ireland; resident of United States twenty-five years, in New Orleans one year; laborer. Admitted to Charity Hospital, Ward 26, Oct. 8, 1873. Was sick since October 4. At time of entrance, high fever; red swollen gums; restless. On October 9 albumen and casts and bile appeared in the urine. On October 17, when the patient was convalescent, the urine contained but a small quantity of albumen. The following observations were begun on the sixth day of the disease and continued up to the nineteenth day and embraced the period of convalescence:

Date.	Pulse.		Resp.		Temp.	
	M.	E.	M.	E.	M.	E.
1873						
Oct. 11	75	70	31	36	100.7°	100.6°
" 12	68	72	30	36	98.6°	98.7°
" 13	60	61	34	36	98.6°	98.6°
" 14	60	66	36	30	98.9°	99.2°
" 15	58	56	32	32	99.2°	99.6°
" 16	58	60	26	26	99.4°	99.6°
" 17	52	62	30	36	99.4°	100.4°
" 18	60	58	30	30	100 °	100 °
" 19	58	60	28	26	99.3°	99.6°
" 20	60	62	28	28	98.2°	99.7°
" 21	80	80	28	28	99.7°	99.8°
" 22	80	70	28	26	99.2°	99.8°
" 23	86	68	26	28	100.3°	100 °

In the preceding case we observe that the lowest point in the action of the heart was reached on the seventeenth day of the disease, when the pulse was only 52, notwithstanding that the respiration was 30. It is also worthy of note that as in many other cases of yellow fever, both during convalescence and in the state of depression preceding death, the temperature fell below the normal standard. This, however, is not always so in fatal cases, which frequently terminate with high temperature.

*Case 9.*—Yellow fever followed by malarial fever. John Cloney; native of Liverpool; age 26. Entered Charity Hospital, Ward 26, Oct. 14, 1873. Patient had been working on rice plantation twenty-five miles above New Orleans. On October 1 was seized with chills and fever. Yellow fever appeared to have been engrafted on the paroxysmal fever. After producing its characteristic phenomenon, the malarial fever again appeared and was arrested by the free use of quinin.

Date.	Pulse.		Resp.		Temp.		REMARKS.
	M.	E.	M.	E.	M.	E.	
Oct. 14	100	118	20	28	100.8°	104.6°	Pain in head, epigastrium and back; perspiring freely; urine contains albumen, red color.
" 15	98	100	18	21	100.9°	101.5°	Perspiring; appetite gone; pains relieved; conjunctiva yellow and tongue slightly coated.
" 16	96	92	18	18	100.8°	100.4°	Improving; urine contains albumen
" 17	88	96	18	22	100.2°	100.5°	Improving; albumen in urine.
" 18	92	94	18	21	99.2°	100°	Continues to improve; pulse intermittent.
" 19	80	84	18	24	99.8°	99.6°	Improving.
" 20	84	86	22	22	99.8°	102°	Fever appeared in the day.
" 21	86	86	22	22	100.6°	102°	Fever.
" 22	84	86	20	22	99.5°	102.2°	No albumen in urine; fever; pulse irregular and patient very nervous.
" 23	86	100	16	14	99.7°	102.6°	Fever, very nervous; hands tremble.
" 24	80	82	14	12	99.7°	100°	Quinin freely administered; perspires; abatement of fever; patient very nervous; perspiring freely; respiration irregular and oppressed.
" 25	80	..	14	..	99.6°	..	Nervous; respiration irregular; twitching of muscles; no albumen in urine, and rested.
" 26	94	..	16	..	99.4°	..	Perspiration, rest and sleep during the night; hands and limbs very tremulous and nervous.
" 27	84	80	22	21	99.3°	100°	Improving.
" 28	80	..	18	..	100.2°	100.2°	Improving.
" 29	80	84	18	18	100.2°	100.7°	Improving.
" 30	..	..	..	..	100.6°	..	..

The diagnosis in this case presented some difficulty; with reference to the question whether the disease was yellow fever or remittent malarial fever. It is worthy of note that while the albumen was present in the urine of the yellow fever, it was absent during the subsequent attacks of malarial fever.

*Case 10.*—Yellow fever succeeded by intermittent fever; the latter disease arrested by quinin; recovery. H. M., age 22; native of Germany; butcher; has resided in New Orleans for four years. Says that he had fever four days before entering the hospital. Entered Charity Hospital, Ward 24, Oct. 3, 1873, with high fever, intense jaundice and capillary congestion. The fever intermittent October 8. The following record of temperature embraces the period of convalescence from yellow fever, and the appearance of the periodic malarial chills:

Date.	Pulse.		Resp.		Temp.		REMARKS.
	M.	E.	M.	E.	M.	E.	
1873.							
Oct. 9	96	100	26	28	100.2°	100.6°	Intense jaundice; capillary congestion.
" 10	94	90	24	24	99.8°	100.4°	Intense jaundice; capillary congestion.
" 11	98	88	25	23	100.7°	100.4°	Intense jaundice; capillary congestion.
" 12	82	80	22	24	100.6°	100°	Jaundice disappearing.
" 13	84	88	22	24	100.7°	100.8°	Improving; sitting up.
" 14	84	72	24	22	101.9°	99°	Intermittent pulse.
" 15	82	104	22	25	100.6°	104.6°	Chill during day, followed by fever.

\* Normal.

In this case the patient had had repeated chills and fever during the summer and fall, which continued up to the time of the attack of yellow fever. This latter disease induced its cycle of changes, and was of a continuous type. Six days after the subsidence of the yellow fever febrile stage, the malarial fever reappeared at stated intervals and manifested its characteristic paroxysmal phenomena.

*Case 11.*—Yellow fever; hemorrhage from mouth and tongue; jaundice; pulse reduced during convalescence to 42 per minute; treated with sulpho-carbolate of sodium; recovery. Telespert Brutet; age 20; native of Canada; laborer. Has resided in New Orleans two weeks. Entered Charity Hospital, Ward 13, October 28. Attack of fever began with a chill which lasted three hours and was followed by intense headache and pain in epigastrium, back and lower extremities. From the account given by the patient, he appears to have entered the hospital on the fourth day of the attack. The following is the record of the pulse, respiration and temperature:

Date.	Pulse.		Resp.		Temp.		REMARKS.
	M.	E.	M.	E.	M.	E.	
1873.							
Oct. 28	*	*	..	30	99.5°	102.2°	Conjunctiva yellow, face and chest with a tinge of yellow; tenderness of epigastrium; pain in head, back and lower extremities; nausea and vomiting; stomach irritable, retains nothing but fragments of food. Vomited matter streaked with blood; tongue coated in the center, very red at tip and edges; gums red; mucous membrane of mouth red and ecchymosed in places; conjunctiva injected; surface injected; pulse feeble and irregular, cannot be counted; patient very weak; urine loaded with albumen and casts; strong acid reaction.
"	72	76	20	18	99°	101°	Thirst and dryness of mouth continue; jaundice increases; action of heart very feeble; urine red and albuminous.
" 30	60	54	20	18	99.2°	99°	Slept for a few hours; appears to be better; vomiting almost entirely arrested; pulse slower but stronger.
" 31	44	44	18	16	97.6°	98.4°	Slept well during night; heart beats feeble; respiration slow but deep drawn; improving; gums and tongue bleeding; spits blood; urine albuminous.
Nov. 1	42	50	14	16	98.2°	101.8°	Hemorrhage from tongue and gums continues; heart actions feeble; urine albuminous; general symptoms improving; jaundice well marked.
" 2	50	54	20	23	98.2°	101.8°	Heart still beating feebly; hemorrhage from tongue and gums; otherwise improving.
" 3	54	44	18	18	98.6°	98°	Tongue moist and not so red; hemorrhage stopped; action of heart still very feeble.
" 4	44	..	17	..	98.6°	..	Improving.
" 5	44	..	16	..	98.8°	..	Improving.
" 6	46	42	20	20	90.4°	99.8°	Continues to improve.
" 7	48	..	20	..	98°	..	Convalescent.

\*Feeble, irregular.

This patient was treated from October 28 to November 2 with 20 grains of the sulpho-carb. of sodium every three hours.

In the preceding case, coupled with a small amount of black vomit and continuous hemorrhage from the mucous membrane of the mouth, there was depressed temperature, slow pulse and a very feeble action of the heart. Although the prognosis in this case was unfavorable for at least six days, the patient passed by slow stages to complete recovery.

The following cases of yellow fever treated in my wards of the Charity Hospital in the autumn of 1873, were all attended to a greater or less extent with jaundice and the observations upon the pulse, respiration and temperature relate to the period of convalescence:

*Case 1.*—E. S., age 27; attacked with yellow fever September 18. During convalescence, while the conjunctiva and skin were still yellow, the pulse ranged from 56 to 61, respiration from 17 to 22, and the temperature between 98.5 and 100 degrees.

*Case 2.*—J. J., age 21; laborer; native of Wales; contracted

fever in Memphis, Tenn., September 10; during convalescence while still jaundiced, pulse 68 to 97; respiration 22 to 28; temperature 99.5 to 102 degrees.

Case 3.—H. S., age 20; native of Germany; laborer; attacked Sept. 29, 1873. During convalescence, pulse 43 to 70; respiration 12 to 14; temperature 99 to 100 degrees.

Case 4.—H. A., age 40; native of Germany; attacked with pain in head and back, and fever Oct. 3, 1873; entered Charity Hospital, Ward 27, October 6. October 8, evening, pulse 79; respiration 28; temperature 102 degrees. October 9, morning, pulse 92; respiration 27; temperature 102.5 degrees; evening, pulse 94; respiration 27; temperature 102.5 degrees. October 10, morning, pulse 78; respiration 22; temperature 97.9 degrees; evening, pulse 75; respiration 22; temperature 99 degrees. October 11, morning, pulse 58; respiration 19; temperature 97 degrees; evening, pulse 63; respiration 21; temperature 98.7 degrees. October 12, morning, pulse 66; respiration 20; temperature 98; evening, pulse 56; respiration 20; temperature 98.5 degrees. October 13, pulse 64; temperature 97.5 degrees.

Case 5.—F. H., age 18; native of Kentucky; laborer; admitted to Charity Hospital, Ward 13, Oct. 3, 1873, second day of disease. October 8, convalescent, but still jaundiced; pulse 50; respiration 20; temperature 98.5 degrees. October 9, morning, pulse 54; respiration 20; temperature 97.4 degrees; evening, pulse 62; respiration 20; temperature 98.6 degrees. October 10, morning, pulse 56; respiration 18; temperature 97.8; evening, pulse 58; respiration 20; temperature 99.6. Discharged October 12.

Case 6.—G. O., age 35; native of Ireland; laborer. Entered Charity Hospital, Ward 25, on third day of disease. October 8, moderate fever; pain in head, back and epigastrium; evening pulse 93; respiration 23; temperature 101 degrees. October 9, morning, pulse 89; respiration 29; temperature 100 degrees. Conjunctiva and skin yellow; urine contains bile and albumen; evening, pulse 85; respiration 26; temperature 100 degrees. October 10, morning, pulse 85; respiration 23; temperature 99.5 degrees; evening, pulse 93; respiration 26; temperature 99.5 degrees. On the 9th the urine was suppressed; great capillary congestion of the extremities, face and neck; black vomit during the night of the 10th.

Post-mortem examination revealed the characteristic lesions of yellow fever. If the last case be compared with the four preceding cases, which terminated favorably, we observe that in them the pulse was not so accelerated as in the fatal case, with urinary suppression and black vomit.

Case 7.—Yellow fever; jaundice; recovered. L. K., age 19; native of France; taken sick on October 18, 1873 with a chill followed by fever which continued for five days, up to 8 p.m., on October 23. During the period of convalescence, extending from the fifth to the twelfth day of the disease, the temperature ranged from 102 on the fifth day to 97.5 degrees on the eighth day; the pulse ranged from 60 to 86 beats per minute, and the respiration from 20 to 30 per minute. The pulse descended gradually from 86 on the fifth day with a temperature of 102 degrees, to 60, with a temperature of 98.8 degrees, on the tenth day of the disease.

Case 8.—Yellow fever. Maurice Pierre; age 28; native of Switzerland; came down the Mississippi River from St. Louis, and in passing Memphis went ashore for a short time. After having been in New Orleans for five days, the patient was seized with a chill on October 19, which was followed by a fever of continued type and which did not abate until October 22. Entered the Charity Hospital evening of October 21 with a temperature of 103.5 degrees. From the fourth to the ninth day of the disease, the temperature ranged from 97.5 to 101.2 degrees; pulse from 56 to 78; respiration from 24 to 32. Both the respiration and the pulse were at times intermittent. The urine contained but small quantities of albumen and the jaundice was comparatively slight in this case; notwithstanding the apparent mildness of the fever, the pulse descended to 56 beats per minute and was intermittent and irregular.

Such facts indicate that the slow and intermittent action of the heart in yellow fever during convalescence and in fatal cases during the period of calm or depression following the active febrile stage, is not solely due to such matters as the bile in the blood, but rather to the structural alterations of the muscular fibers which I have fully described.

Case 9.—Yellow fever; jaundice; slow pulse; recovery.

Dennis Manning; age 28; native of Ireland. Has resided in New Orleans seven years. Entered Charity Hospital, Ward 24, November 4. Tongue red at tip and edges; gums congested, red and bleeding; intense thirst; vomiting; can retain nothing upon stomach; great capillary congestion; restless and sleepless; hiccup; urine loaded with albumen and casts. Ordered sulpho-carbolate of sodium, 20 grains every four hours; ice bag to epigastrium; ice-water injections to rectum; iced milk; fragments of ice in mouth.

November 7, pulse 66; respiration 20; temperature 100 degrees at 8 a.m.; November 8, at 8 p.m. 101 degrees; conjunctiva yellow and congested; surface of body yellow and congested; 8 a.m., pulse 60; respiration 20; temperature 98.5 degrees. At 8 p.m., temperature 99. Restless and prostrated; urine loaded with albumen and casts.

November 9, 8 a.m., pulse 66; respiration 16; temperature 99 degrees; 8 p.m., pulse 66; respiration 14; temperature 98 degrees. Tongue red at tip and furred, cracked and bleeding; gums congested and bleeding; great muscular prostration; action of heart slow—beats feeble. Treatment continued.

November 10, 8 a.m., pulse 60; respiration 20; temperature 98 degrees. 8 p.m., pulse 60; respiration 20; axilla 99 degrees.

November 11, tongue and gums red and bleeding; jaundice and great congestion of capillaries of surface and extremities which present a purplish mottled appearance; urine loaded with albumen; dizziness in head. At 8 a.m., pulse 52; respiration 20; temperature of axilla 97.6 degrees. At 8 p.m., pulse 68; respiration 20; temperature 100. Improving; bleeding from tongue and gums almost entirely arrested; dizziness in head still continues; pulse slow; but action of heart is feeble and patient incapable of any great exertion.

November 12, pulse 52; respiration 18; temperature 99.2 degrees. At 8 p.m., pulse 54; respiration 20; temperature 100 degrees.

November 13, 8 a.m., pulse 51; respiration 20; temperature 99 degrees. At 8 p.m., pulse 48; respiration 20; temperature 99 degrees.

November 14, 8 a.m., pulse 48; respiration 16; temperature 99.5 degrees. Continued to improve and was discharged in good health.

Case 10.—Yellow fever, engrafted on paroxysmal malarial fever and followed by remittent fever and phthisis pulmonalis. Charles Scott; age 32; native of New Brunswick; carpenter; resided in New Orleans for eight months. Admitted to Charity Hospital, Ward 13, Sept. 29, 1873. Says that three days before entering the hospital he was seized with a chill which lasted five minutes, and was followed by a fever of eight hours duration. The fever was again followed by chill and fever. After the relief of the paroxysmal fever by sulphate of quinia, a continuous fever with pain in head and back appeared on October 5. The following observations were recorded in this case, illustrating the superinvention of paroxysmal fever during convalescence:

Date.	Pulse.		Resp.		Temp.		REMARKS.		
1875	M.	E.	M.	E.	M.	E.			
Oct. 8	67		25		100	°	Patient has no fever but has pains in lumbar region.		
" 9	60	64	22	22	99.4°	100	°	Feels fairly well, but weak; albumen in urine.	
" 10	60	62	20	22	99.6°	101.3°		Appears to be improving; albumen in urine.	
" 11	52	59	25	24	100.4°	101.2°		Did not rest well during night; tongue furred and very dry; thirsty; drank ice water but vomited it up.	
" 12	52	52	22	22	100.2°	101	°	Conjunctiva and skin yellow; swollen; tongue red and apparently with spots of blood on it.	
" 13	51	56	24	28	99.5°	100.5°		Jaundice; heaviness; red gums and tongue; pain and heaviness in epigastrium.	
" 14	50	58	26	26	100.1°	100.5°		Severe pains in epigastrium; tongue red at tip and edges; gums red; jaundice.	
" 15	52	62	26	28	100	°	101.5°	Jaundice; urine abundant, albuminous.	
" 16	54	60	30	28	100	°	101.5°	Jaundice; urine abundant, albuminous; pain in epigastrium and lower extremities.	
" 17	48	58	28	26	100.5°	102.5°		Jaundice and great congestion of capillaries; urine abundant and contains albumen and casts; pains in epigastrium and lower extremities.	
" 18	54	52	30	30	101.2°	101.2°		Congestion of capillaries; jaundice.	
" 19	50	52	24	18	101	°	102	°	Fever in evening; patient very weak, cannot sit up in bed; nervous; pains in epigastrium.
" 20	70	56	28	26	101	°	102	°	Feeling of uneasiness in epigastrium; albumen in urine; jaundice diminishing.
" 21	72	80	28	28	101.1°	102.2°		Jaundice diminishing; patient feels stronger.	

" 22	78	80	26	26	101	102	Still very weak and exhausted by least motion.
" 23	58	58	20	20	100.5	101	Appears to be much better.
" 24	..	..	..	..	103	103	Paroxysm of fever.
" 25	..	..	..	..	103	101	Fever; quinin freely administered.
" 26	74	76	32	24	101	98	Fever subsided.
" 27	80	68	24	28	99	101.5	Convalescent.
" 28	80	..	26	..	101	..	Convalescent.

After the subsidence of the yellow fever, it was found that the temperature did not subside, but still kept up, and upon careful examination I found evidence of phthisis pulmonalis in both lungs. The following is the record of the pulse, temperature and respiration after the subsidence of the yellow fever:

Date.	Pulse.		Resp.		Temp.	
	M.	E.	M.	E.	M.	E.

" 16	90	..	36	..	102 °	..

Case 11.—Yellow fever. Charity Hospital, Ward 25; John Pflum; age 26; native of St. Louis; fever begun with a chill of half an hour's duration, followed by fever on October 7. The fever continued up to the time the patient entered the hospital, Oct. 20, 1873. Had been sick two days before entering the hospital.

## REMARKS.

October 20.—High fever; skin congested; conjunctiva of eyes very much congested and injected; tongue furred and red at edges; great pain in forehead and throat; passes urine only with great effort; ordered iced milk and ice fragments in mouth; gums congested.

October 21.—Passes urine with great effort; urine loaded with albumen; complete suppression of urine during night; grows restless and talks at random during the night.

October 22.—Ice cold injections ordered and repeated three times; after the third injection, passes quite a quantity of urine; when patient gets to sleep complains of nausea, when the sulpho carb. of sodium was ordered in 10 grain doses, repeated every two hours, which afforded relief to the symptoms and nausea.

October 23.—Patient slept well during night; has been able to drink a glass of milk and cup of beef tea; during the night, passes urine quite freely, loaded with albumen, and urine is greenish-yellow in color.

October 24.—Bowels moved; feels great relief and expresses himself as better; continue the sulpho carb. of sodium as above ordered; drinks milk and beef tea; urine passes pretty freely; albumen present in urine but decreasing in amount; complains of hunger; bowels moved.

October 26.—Tongue clearing off; skin begins to clear up; great hunger; urine returning to the normal standard; quantity of urine increasing.

October 27.—Patient sat up during the day.

October 28.—Goes about the ward, but watched; albumen disappears from urine.

October 29 and 30.—Patient goes about, is discharged and goes out cured.

Case 11.—Yellow fever. Adolph Kammer; age 21; native of Sweden, has been in America six years, in St. Louis, Mo. Admitted in the Charity Hospital, Ward 13, November 1, 8 P.M. Had been in New Orleans two weeks; sick two days previous to entrance.

## REMARKS.

November 2.—Skin hot and dry; slight jaundice; gums congested, tongue dry and swollen; kidneys acting imperfectly. Passed a small quantity of urine by catheter; urine loaded with albumen; ice water injection caused passage of urine during day and evening.

November 3.—Complains of stomach, but relieved by ice sprays to epigastrium. Has been treated with sulpho carb. of sodium, 5ij divided into 6 powders, one powder (20 grains) every four or six hours; milk punch, brandy and beef tea, and small lumps of ice in mouth. At night slight hemorrhage from the gums; passed urine quite freely towards the morning of November 4; urine dark colored and loaded with albumen and bile.

November 4.—Very quiet during the day; perspires freely and seems to be in better condition; passes urine freely. Continue sulpho carb. of sodium in the same doses. Milk punch, beef tea and ice. Wash the face and hands with tincture of camphor and water; this seems to refresh him greatly. Bowels have been moved.

November 5.—Passed a good night, had some sleep, begins to look more cheerful and desires to sit up.

November 6.—Passed a very comfortable night; jaundice disappearing; urine freely passed; urine still contains albumen, but the quantity is diminished.

November 7.—Doing well, sits up; all pain disappeared, although quite weak; eats and sleeps well; jaundice disappearing.

November 8.—Patient still improves; albumen disappeared from urine; walks around.

November 9, 10, 11 and 12.—Rapidly improves; jaundice disappearing rapidly; slight traces of yellow in eyes.

November 13.—Discharged from observation and leaves, November 17, quite well.

(To be continued.)

THE IDENTIFICATION CARDS OF THE  
U. S. ARMY.

BY MAJOR CHARLES SMART, U. S. A.

Every recruit enlisted in the U. S. Army, besides being examined as to his physical qualifications to undertake military duty, is subjected to a careful scrutiny for scars, moles, tattooings and other permanent marks on his person by which his identification may at any time be determined. These are recorded in their proper locality on a card bearing a front and back view, in outline, of the human figure. The card of each recruit, as soon as completed, is forwarded to the Surgeon-General's Office, where it is compared with the cards of the deserters, ex-military convicts and other undesirable men that have been filed in the office during the past six years. Should the result of this comparison be favorable to the man, his card is then placed in an alphabetical file and there continues until the honorable termination of his service. The office of the Surgeon-General thus contains an identification card for every enlisted man now in the military service. Should any of these men desert or be convicted of some military crime involving dishonorable discharge, his card would immediately be transferred to the file of "undesirable men."

For convenience of reference and comparison, the cards of the undesirable files are arranged systematically, the first division in accordance with location of scars, those cards showing a scar on the right forehead being in one file box or drawer, on the left forehead in another, and so for fifty-eight anatomic locations or divisions of the surface of the body. Each of these files is subdivided by height into seventeen sections beginning with "64 inches and under" and proceeding by half-inch gradations to

"72 inches and over;" and each of these sections is, if need be, separated into two groups by color of eyes, blue or brown. To permit of accuracy in the determination of color, the Surgeon-General has issued to medical and recruiting officers chromolithographed standard eye colors, by which the various shades may be indicated with precision, as Blue, No. 1; Brown, No. 4, etc., on the identification card. The cards of all undesirable men having the same height and color of eyes, with scars similarly situated on the body, are thus brought together and used with facility for purposes of comparison.

The second division of the files is arranged in accordance with location of birth marks, including moles, and these are subdivided as in the case of scars by height and color of eyes. These two divisions give 3,944 final groups— $2 \times 58 \times 17 \times 2 = 3,944$ . Up to this time some of the sub-files have not required division by height or eye colors, on account of the small accumulation of cards of that particular kind.

The third division provides for the cards of men who have suffered amputations, as of part of the ear, toes or fingers. These give twenty-three sub-files without division by height or eye colors. The fourth division consists of tattoo markings which are separated into "distinctive" and "common." The first includes letters and initials, words, phrases, numbers and common tattoos in unusual locations; the second consists of hearts, crosses, anchors, sunbursts, flags, coats of arms, ballet girls, etc. The latter are grouped by location.

Separate files are kept for white and for colored men. The negroes are not subdivided by eye colors; but a sub-file is kept for those colored men who have blue eyes, this color in itself being a distinctive mark for these cases. This system of filing gives a total of 337 divisions, with 7,033 subdivisions, and it has the merit of being susceptible of expansion or contraction to meet the requirements of the service in which it is engaged. It may be contracted by omitting to subdivide by the eye colors, by making fewer subdivisions for height and by increasing the size and lessening the number of the surface locations, and it may be expanded by subdividing those anatomic locations which call for such treatment by a large accumulation of cards.

If an undesirable man has several notable scars on his person a card is made to be filed under the location of each of the scars, to insure his detection. A man having a prominent scar on the right forehead and another on the left shin has a copy of his identification card filed under both of these locations. In examining the files a margin of one inch below and half an inch above the recorded height is assumed to be needful on account of inaccuracy in taking measurements. The card of a recruit said to be 66 inches tall is compared with the cards of deserters from 65 to 66.5 inches. This suffices to cover the limits of inaccuracy in ordinary cases.

This system has proved most efficient in the Army. The Bertillon system of measurements is merely an index by which the card or record of an individual may be discovered in a mass of others; his identity is determined subsequently by reference to personal marks and other data. An error in any one of the various measurements will throw the investigator off the track of the required individual. In the U. S. Army system the personal marks themselves consti-

tute the index and there is no liability to get off the track except in the case of height which is specially guarded as above mentioned.

## SOCIETY PROCEEDINGS.

### Louisville Academy of Medicine.

The regular meeting of the Academy was held in their rooms Monday evening, January 21, Dr. F. C. Simpson, Vice-President, in the chair. Dr. J. M. Ray exhibited a case of double empyema of the antrum, in which different operations had been done on the two sides. The first operation had been done in July last; with the aid of a dental surgeon the second molar tooth was drawn, an opening drilled through and a gold tube introduced, the cavity being washed out through this opening. The operation on the other side had been done in September, 1894, the opening being made through the canine fossa, and a Miles antrum soft rubber drainage tube introduced; of the two the latter operation seemed the most effectual as the drainage was better through the opening in the canine fossa. The case was exhibited with the drainage tubes *in situ*. The transillumination test in this case had not been satisfactory, owing to the double trouble.

DR. T. C. EVANS stated that in his experience the light test was very unsatisfactory, the diagnosis being made more from the other symptoms.

DR. DABNEY stated that in his experience the lamp test had proved very satisfactory. The points to be observed in its application which may often cause it to be unsuccessful, were: 1, have the room totally dark; and 2, always ask if patient has a plate in the mouth.

DR. VANCE exhibited a case of double inguinal hernia which has been reported in detail in *Mathews Medical Quarterly*, Vol. 1, page 225, and in whom the hernia has not descended for eight months, the cure being almost entirely complete from the mechanical effect of the truss described in the article above referred to.

DR. RODMAN showed a case who had been kicked by a horse, over a truss, which was worn over an irreducible hernia. A week later he was operated on, an incision was made and fecal matter with pus escaped, and continued to pass through the opening for a week. The case was undoubtedly a rupture of an irreducible hernia with spontaneous reduction and a radical cure resulting from the inflammatory action. He also reported and exhibited six other cases in whom an operation for the radical cure of hernia had been done, the length of time elapsing being from a few months to eighteen months without a relapse. In one of these cases while tying off the sac he had included the appendix and amputated it, having considerable hemorrhage from the artery. Kocher's method of operating was used.

DR. W. H. WATHEN reported a case of double intra-ligamentous cyst, the two cysts being on the same side but entirely separate and distinct; the largest perhaps originated in the hylum of the ovary, the other perhaps in the parovarium. The patient is now convalescing, and the cyst is being washed out, first with peroxid of hydrogen, followed by sulphurous acid 1 to 10, which kills offensive odors most excellently. Dr. Rodman then showed a specimen of acute necrosis of the bones of the leg following acute osteomyelitis. Ten weeks ago, the patient, a boy of 14, fell under a horse, his leg being caught under it; there was no wound, no fracture, but great pain occurred in the tibia some little time afterward. There was hectic, temperature 103 degrees, pulse 130. When first seen sinuses riddled the leg throughout. A preliminary operation was done, and no sound bone was found. An amputation was immediately done as he took chloroform poorly. Examination of the leg afterward found two spontaneous fractures at the epiphyses and the bone necrotic throughout, the process extending to the soft tissue.

The papers of the evening were then read, Dr. Vance reading Dr. Bullitt's paper in his absence on the "Truss Treatment of Hernia," and the one on the "Operative Treatment of Hernia," was read by Dr. Rodman.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, FEBRUARY 2, 1895.

SYPHILIS IN THE ETIOLOGY OF NERVOUS DISEASES.

Within a few years there has been a great change in views regarding the importance of syphilis in the causation of nervous diseases especially tabes dorsalis and parietic dementia. For several years after the publication of ERB's tables on tabes there was a contest, between those who regarded syphilis as the chief cause and those who denied its etiologic importance. Gradually the doubters have been silenced, and it is now admitted that a large majority of all cases of parietic dementia and tabes present a syphilitic history. Of late, however, we note a tendency to carry this view too far. A recent writer asserts that parietic dementia is only a late stage of syphilis of the brain.

Another writer argues that all cases of tabes are to be regarded as of syphilitic origin, for he says the proportion of cases claimed to be non-syphilitic has been steadily diminishing for a number of years, and if the present rate is maintained they will soon disappear from published tables. Apparently the lameness of this deduction does not occur to the writer but we are forcibly reminded of the humorous logic of MARK TWAIN regarding the shortening of the Mississippi River. This stream he said, owing to straightening of the channel, becomes shorter every year, and from known data he estimated that at the end of a few centuries it will be only four miles in length. It is only necessary to project the figures a little further to find a time when the stream shall have disappeared.

We admit that syphilis plays a most important rôle in the production of tabes and paresis. Probably 80 per cent. are of luetic origin, but to argue

from this fact that they necessarily all are is not only a lame deduction, but it is fraught with most serious consequences. Not only may the innocent be branded with a loathsome disorder, but the medico-legal relations of such a doctrine must not be lost sight of. Almost all insurance applications have a reference to this disorder and the statements made by applicants are warranties on which the policies are issued.

We think that medical science is quite as much in need of logicians as it is of experimenters and observers.

MEDICAL TEMPERANCE ASSOCIATION.

This society formed at Washington in 1891, and composed of members of the AMERICAN MEDICAL ASSOCIATION, appears to be growing into prominence in many unexpected ways. Already its influence has been noted in many recent papers on the alcoholic problem, and several foreign journals have referred to a similar English society, and this Association, as the pioneers of this new field of research. They have both been very highly commended as scientific efforts to reach some intelligent conceptions of the underlying forces which explain the rôle of alcohol in medicine and as a beverage. Both of these societies are composed of members of the British Medical and AMERICAN MEDICAL ASSOCIATIONS, and both are led by eminent men. SIR BENJAMIN RICHARDSON is President of the English society and DR. N. S. DAVIS of the American society. Each society publishes a journal which presents papers and researches concerning alcohol, in a calm dispassionate way, particularly addressed to physicians.

Studies of alcohol, especially from its scientific side, have increased very rapidly within the past few years, and persons who have not followed up this topic will be surprised to find that a bibliography by no means complete, covers several thousand books, pamphlets and articles, of exclusive scientific studies. This does not include the half moral, half scientific dogmatic papers and lectures which fill the lay and medical press. The defenders of the various theories of old text-books of medicine frequently find themselves belated and need to become acquainted with the results of modern study before they can speak authoritatively.

A significant movement, outside of medical circles, to investigate the alcoholic problem has begun by a large number of teachers and college presidents and others of eminence in various parts of the country. While it is unusual to find so many very influential and really strong men united to investigate problems of this character, the work of the committees on the physiologic and pathologic aspect of the subject as projected, gives a strong impression of a very limited knowledge of both the subject and the proper

methods of study. The personal opinions of vast numbers of good men on such a topic are open to so many sources of error as to be practically worthless. If this inquiry was made of the sixty thousand physicians in this country, who have both practical and theoretical knowledge of alcohol and its effects, some facts of comparative value would be found.

The question of personal opinions on this topic would seem to be a very primitive way of ascertaining facts. It is the conclusion of all students that the alcoholic problem is scientific, and one of exact study, not of morals or ethics, and all efforts on the social and moral side will only deepen the confusion and obscurity of the topic. The Medical Temperance Association is a movement on the line of exact study, and a protest against theories of any kind that are not sustained by careful investigation and study of all the facts. To assume that this or that theory is true, because antiquity and the fathers believed it is not the spirit of modern science nor of modern medicine. If any present theories concerning alcohol are true, the evidence is demanded and tested, and if there is no reliable evidence that will bear critical examination, the theory can not be held as true, no matter how widely it has been accepted by all persons. However much the new truths may conflict with our previous conceptions or customs of life, they can not be kept down or suppressed. The alcoholic problem demands a new study from a wider point of view, and the Medical Temperance Association has the floor. If the medical profession had taken up this subject above the currents of prejudice and popular delusions no committee of non-sectarians would ever have had occasion to investigate this problem.

The coming meeting of the AMERICAN MEDICAL ASSOCIATION at Baltimore will also bring the fourth anniversary of the Medical Temperance Association, mostly composed of members of our ASSOCIATION, which meets at the same time and place. It would seem that the profession should take up this subject more actively and help on the study and work of investigation from every standpoint, so that some facts may be ascertained which all can agree upon as closely approximating the final truths of alcohol and its use.

#### SECTION OF NEUROLOGY AND JURISPRUDENCE.

While the promise of great activity and numerous excellent papers and studies are noted in all the Sections at the coming meeting at Baltimore in May, the Neurological Section is making an effort to give an exhaustive review of certain special topics that will be of unusual interest.

One of these will be epilepsy, medically, surgically and therapeutically considered. The other, hypnotism, its medical, therapeutic and medico-legal rela-

tions. This will cover the new realm of mental therapeutics in crime relations, and the novel applications of so-called new laws of mind over matter. The third topic will be the therapeutic relations of electricity in nervous diseases. This will bring out some of the recent resources that have been the subject of some comment. The plan of having several distinct symposiums on topics of unusual interest, will be highly appreciated and has become a popular feature of the British Medical Association. It brings to the hearer a study of the subject that is very pleasing and suggestive.

The officers of the Section, DR. D. R. BROWER, of Chicago, Ill., as chairman, and DR. T. D. CROTHERS, of Hartford, Conn., as secretary, especially desire to call attention to these studies, and invite correspondence with persons who may desire to read papers on these topics, or discuss them from any point of view.

#### NEW MEDICAL PRACTICE ACT.

The State of West Virginia is apparently to have a new Medical Practice Act, the House bill for that purpose having been favorably reported by the Judiciary Committee of that body.

The bill provides that the State Board of Health shall at such times as a majority shall deem proper, hold examinations for the licensing of practitioners of medicine. The bill provides for both written and oral examinations "covering all the essential branches of the sciences of medicine and surgery and the examination shall be a thorough and decisive test of the knowledge and ability of the applicants."

Should any applicant profess a desire to practice according to the "homeopathic" school, then the Board "shall call to their assistance a homeopathic physician duly licensed to practice medicine in this State."

The bill is in the right direction, but in our opinion the words, "practice of medicine" should be clearly defined, so that when cases arise under it there may be no quibble as to the meaning of the statute.

#### CORRESPONDENCE.

##### Treatment of Typhoid Fever.

KALAMAZOO, MICH., Jan. 25, 1895.

To the Editor:—By following the suggestions made in an article in the JOURNAL of December 4, by W. S. Caldwell, M.D., soliciting correspondence as to the antiseptic treatment of typhoid fever as advocated by Dr. John Eliot Woodbridge, I would give a brief outline of the treatment of two cases as stated in a paper which I read before the Kalamazoo Academy of Medicine, Oct. 15, 1894, on "The Abortive Treatment of Typhoid Fever." Sept. 19, 1894, I was called to see a lad about 10 years of age who lived in the celery region in a low and marshy part of the city; he had been complaining for four or five days previous with headache, backache and general languor. I found him with a brownish-gray tongue,

tympanitis, diarrhea and fever, his temperature ranging from 102 degrees F. in the forenoon to 104 degrees F. in the afternoon. I first gave him large doses of quinin for two days, which did not relieve his condition, but satisfied me that it was not malarial but genuine typhoid fever. I began the antiseptic treatment, as recommended by Dr. Woodbridge, September 21, the third day after first seeing him; the medicine was given in small doses every thirty minutes. I also gave a large dose of turpentine occasionally and used it externally when necessary. September 21, when beginning the treatment the morning temperature was 102 degrees F. and the evening temperature 104 degrees F. September 22, morning temperature 102 degrees F.; evening temperature 103 degrees F.; September 23, morning temperature 103½; September 24, evening temperature 104 degrees F.; September 25, morning temperature 102 degrees F.; September 26, evening temperature 103 degrees F.; September 27, morning temperature 102 degrees F.; September 28, I did not see him; September 29, morning temperature 101 degrees F.; September 30, evening temperature 101; October 1, evening temperature was 101½ degrees F.; October 3, temperature 100 degrees F. In this case the temperature began to vary, gradually, a little for two or three days, and then diminish a little each day after beginning the treatment, and on the eleventh or twelfth day temperature was so near normal and other symptoms so favorable that I considered it safe to dismiss him. I saw him about a week after, when he was around the house and had no fever.

My next patient was a man about 33 years of age who called at my office in the evening and I found his temperature 104 degrees F. He had been feeling quite badly for a few days previous, and said that he was taken with a chill. He was suffering from headache, backache and a dull heavy languid feeling. I called at the house the next day and treated him symptomatically for a few days, giving large doses of quinin, calomel, etc., but soon found that it did not diminish the fever and that his temperature assumed a regular typhoidal character. I began the antiseptic treatment September 21, at the same time that I did my other case, and dismissed him on the same day, October 3. After beginning the medicine, the temperature went through about the same degree of decline that it did in the first patient, with the exception that it was normal October 3, when dismissed.

Two or three cases may not be sufficient to establish positive evidence that this treatment is correct, but I can say that it worked better with me in these cases than any plan of treatment which I have followed in typhoid cases, since beginning the practice of medicine about twelve years ago. I hope to hear from other members of the profession who have tried this treatment.

Very respectfully,

FRANK C. MYERS, M.D.

### The Bill for the Re-organization of the Personnel of the Navy.

To the Editor:—Under the pretence of increasing the efficiency of the Navy, this bill seeks to humiliate and degrade the staff corps. To counteract the enormous increase of pay required for 16 rear admirals (major generals) and 234 commanding officers (to command fifty vessels in commission), it proposes to take away from the staff corps some of their pay to help meet these remarkable line changes. Why should a doctor's pay be diminished because of any change in the line? His value does not depend upon the line. The market value of doctors does not depend upon the supply of ensigns. They come from civil life and their pay should be fixed at what good men of their profession are worth. They have educated themselves and no staff officer can ever reach the ultimate high pay of the line, or hope for the re-

markable promotion provided for the line, by this bill. A writer in the *Brooklyn Eagle* forcibly states the case:

"This bill degrades the staff officers and makes the servants of a selected part of the line. No such firebrand has been cast at the Navy since 1855. It is a mistake to think it is wanted by the service at large. It is opposed by 90 per cent. of the line above the grade of lieutenant commander and by every member of the Medical, Pay and Engineer Corps. These corps are absolutely essential to the efficiency of the Naval Service. Can this bill increase the efficiency of the personnel of the Navy if it makes it impossible to secure a competent medical department and places the lives of officers and men in peace and war at the mercy of incompetent men? Can it promote naval efficiency to deride the authority of the engineer officer over his men in the management and care of the complicated and powerful engines of our new ships? Can it promote naval efficiency to place a medical officer so that he can not conduct properly a hospital in which he has line officers, staff officers and enlisted men as patients? With one accord all the staff officers repudiate the ghost of positive rank offered by this bill. There is, indeed, no positive rank conferred, for it is offered in one section and taken away in others. Why should not a medical officer have military command in a naval hospital or in his own department on a ship? Why should not an engineer officer have military command over men around the boilers and engines of a ship? Why should not medical, pay and engineer officers have military command in their own departments at all times and exercise it under the commanding officer, whatever may be his rank, as do all other officers, even the youngest ensign in charge of a gun? How are they to control the men under them if they have no authority by virtue of their orders and commissions? Can a bill which denies this authority and which makes the staff officer regard the words on his commission as satirical, promote efficiency in the Navy? It is a mistake to suppose that this bill is in the interests of harmony and good feeling in the service or that it will definitely settle the controversies which now exist. So far from it, it is a bill productive of discord, discontent and bad feeling. It will, with its reserve list and treatment of the staff corps, cause numbers of dissatisfied officers, and in place of harmony and efficiency it will cause more discord and trouble than the Navy has ever known. It is a mistake to think that staff officers want military rank for any general command. They want military command in their own departments only and under the commanding officer as are all other officers. A similar provision has existed many years in the Army, where discipline is jealously guarded. The staff corps desire simply the Army law, and that is all they ask for. They are commissioned officers and are not any more insubordinate and unworthy of trust than other commissioned officers.

"Aside from this, the other main features of this bill affecting the staff corps are most unjust and seem to reflect the same desire to destroy their efficiency. There are five grades now in each of the three staff corps mentioned. This bill makes six and thus divides each corps into smaller fragments. It thus fixes a smaller number of men who can have any given rank at the same time. The middle grade in each corps is divided, the upper fragment only being given the higher rank. This whole grade once had the higher rank, but now has two ranks owing to stagnation in the line. For some years now the rank of the majority of the members of the Medical, Pay, and Engineer Corps has depended upon promotion in the line, each of these staff officers taking his rank within grades in accordance with a certain line officer with whom he has had to keep pace. Stagnation in the line has made stagnation of rank in the staff, and now this bill rapidly advances the one and holds back the other. It does this not only by dividing the staff corps into a greater number of grades, but now that they would be benefited in rank by the rapid line promotion provided for in this bill if the present system were retained, a new system is most conveniently adopted under which the relation in rank between line and staff now existing is abolished, and the staff corps made to retain much of the damage in rank they have sustained. The division of the staff corps into a greater number of grades is one of the most unjust things in this bill. It is designed for the purpose of depriving forever the staff corps of the rank they once had, and which should be restored to them by this bill—a bill which examination clearly shows is designed to exalt simply the younger portion of the line and to pull down, humiliate and make servants of most of the other commissioned officers of the service.

"A further examination only makes this spirit still more apparent. It has been shown that this bill provides 234 commanding officers for less than fifty ships of war. No ship can have more than one commanding officer, but many must have more than one doctor and one engineer. A ship having a complement of 300, 400 or 500 men goes into battle with one commanding officer. If he falls the next line officer takes his place. It would be inhuman and absurd to send such a vessel to sea in peace or war with one surgeon or one engineer. Even in peace the sickness or death of such men would find no one to take their place. Epidemics on board at sea would find men dying for want of assistance. In war a recent experience has shown how many wounded a few minutes' light at sea produces. Can one surgeon give the necessary aid? Why, everybody knows that many common surgical operations are never undertaken without several assistants. Can one surgeon do what humanity requires? And suppose the surgeon falls in battle, who is to take his place? No one can, if he is acting alone. It is absurd to say that he can not fall in battle, that he is down below safe from shot and shell. In the recent naval battle between the Japanese and Chinese the former lost ten commissioned officers, killed outright, and two of these were doctors—20 per cent. It is absurd to call any man a non-combatant in these days on a ship of war. Most of our ships being of the cruiser class are easily pierced, and perhaps no men occupy a more dangerous position in battle than the engineer force. What would a shot into a boiler or steam pipe mean? Death from scalding to a number of men—who like men in reserve are liable to suffer at any time and yet are not in the heat of the fight. This was the history of our war, and this will be the history that will be repeated. Beside, who is to be depended upon when the whole ship itself is to be used as a projectile, and her steel prow pushed into the hull of her adversary? Is not this making the Engineer Corps combatants, and should not the engineer officer have military command over his men at such a time? Who holds the throttle and who gives the ship her speed through the water and are most liable to suffer from the shock? It is absurd to think of only one engineer for the many complicated engines on a modern man-of-war. Now make the comparison in this bill between the number in line and staff. Two hundred and thirty-four line officers to command fifty or sixty ships with one commanding officer to each ship! How many doctors? One hundred and sixty-five, when two or more are required on many ships and the hospitals on shore require staffs. How many engineers? One hundred and ninety, when several are required on nearly every ship. How many paymasters? Ninety-six for all purposes. Does not this comparison show the line strength in this bill, in which in spite of a number of commanding officers now that can

not be utilized, there is an increase of 30, nearly as many as there are ships, and the medical corps is reduced five numbers—from 170 to 165. Two hundred and thirty-four commanding officers and 165 doctors, 190 engineers and 96 paymasters. Is not this an absurdity? Is not this a line bill and a malicious expensive one at that?

"Examine still other provisions and the unfairness of this bill becomes yet more apparent. In Section 12 it is arranged that there shall be at least twenty numbers made each year in all grades below lieutenant commander. Now as there are seventy-five lieutenants of the junior grade provided, an officer must pass through that grade at the most in a little over three and a half years, and will do so in less time. Now examine the staff corps. A man in any one of these corps must of course wait for vacancies above him in his own corps before he can be promoted. In the Medical Corps, there are forty lieutenants of the junior grade provided in a corps with 165 members, nearly one-fourth of the whole corps. As, during the last twelve years, there have been four numbers made each year, it will take a medical officer ten years to pass through this grade. Less than three and a half years in the line and ten years in the Medical Corps. This is, indeed, a line bill with a vengeance! In the Engineer Corps it will take five or six years to pass through this grade and in the Pay Corps seven years. The unfairness of this is very apparent. The result of this will be that young men in the line will have great rank, while in the staff a man will carry his gray hairs around, even in the lower grades.

"Even in this treatment of the staff corps mentioned there is a curious lack of consistency. In Section 25 it will be seen that in the Medical Corps of 165 members, 30 are allowed with the rank of lieutenant commander. In Section 33 it will be seen that in the Pay Corps of ninety-six members the same number of lieutenant commanders is allowed. In one case less than a fifth, and in the other nearly a third. A strange and curious inconsistency. The number of this rank in the Medical Corps should for every reason be fifty. That is the number of the surgeon's grade now for which the title, staff surgeon is substituted. They were all with the relative rank of lieutenant commander a few years ago, but are now divided in rank simply by line stagnation, and will be forever divided by this bill.

"Furthermore, this bill provides for a criminal result so far as the Medical Corps is concerned. The Medical Corps gets competent men now with great difficulty, and from lack of inducements offered has not had its complement since 1865. What will be the state of that corps under this bill? Every diminution in inducement means a lowering of standard for admission, and under the inducements offered by this bill this standard will necessarily have to be placed so low that the lives of officers and men will be placed in the hands of incompetent persons. Equalization of the rank and pay of the Medical Corps of the Navy should not be made with the line of the Navy, but rather with the Medical Corps of the Army. The market value of a doctor does not depend upon the supply of ensigns and has no relation to the Naval Academy. It depends upon the condition in civil life and upon inducements offered by the other public services, such as the Army and Marine-Hospital service. Vacancies in those services for which there are not suitable men is unknown. In the Army, assistant surgeons have the rank, pay and emoluments of a first lieutenant of cavalry for the first five years' service—pay alone \$1,600—and the rank, pay and emoluments of the grade of captain after five years' service—pay alone \$2,600 (Section 4, act June 23, 1874).

"At the upper end of the corps is one brigadier general. Colonels in the Medical Corps receive \$4,500 on the active list and \$3,375 on the retired list. This bill proposes for the Navy that an assistant surgeon shall enter with the rank of second lieutenant (Army), with his highest pay \$1,200. He will be behind the Army man in his promotion and at the end, after many years, his highest shore duty pay will be \$3,500. The Army ranks are generally full, but the rewards of service are none too great, and there is not much struggling for appointment. It is, therefore, a great mistake to suppose that competent assistant surgeons can be obtained for the Navy at \$1,200 at sea and the rank of ensign. The result will be an incompetent corps. The efficiency of the Navy can not be promoted by destroying or weakening its medical service.

"From every direction the truth of the proposition becomes evident that Congress may improve the pay and position of the line officer, but it can not do so at the expense of the staff without injustice. This injustice would lower the efficiency of the service and make discord and discontent.—AN OFFICER OF THE NAVY.

### Castration for Prostatic Hypertrophy.

Dr. Ricketts to Prof. J. William White.

CINCINNATI, OHIO, Jan. 23, 1895.

*My Very Dear Doctor:*—I received your letter recently concerning the removal of testes for hypertrophied prostate. Since that time I have kept informed upon all things pertaining to this new work, so far as I have been able.

The following communication was just received from the physician who has charge of the patient whose testes I removed on Oct. 26, 1894:

Jan. 22, 1895.

"*Dear Doctor:*—The patient whose testes you removed on Oct. 26, 1894, for hypertrophied prostate, has no obstruction, straining, or severe pain, which he formerly had while urinating. He passes water still too freely, and complains of burning and itching after micturition.

"I would say that he is well and doing nicely.

Very fraternally, L. M. GREEN."

Thus you see that the results in this case verify those of the others that have been reported.

I am thoroughly satisfied that this operation is one that, sooner or later, will become generally adopted for the relief of hypertrophied prostate.

I am also satisfied that to you belongs the credit for first suggesting it; surely for doing the experimental work necessary to establish the facts concerning it.

You may use this letter in any way you deem proper.

I am, very truly, MERRILL RICKETTS, M.D.

Dr. J. Wm. White, Philadelphia.

### BOOK NOTICES.

**Laboratory Guide for the Bacteriologist.** By LANGDON FROTHINGHAM, M.D.V. Illustrated. Philadelphia: W. B. Saunders. 1895. Price 75 cents.

This is an excellent companion for the laboratory table. Several methods of bacteriologic examination are mentioned here that are not in common use, and some of them will save much time over former methods.

**Syllabus of Gynecology;** based on the American Text-Book of Gynecology. By J. W. LONG, M.D. Philadelphia: W. B. Saunders. 1894. Price, \$1.

This syllabus seems to be a complete syllabus of the topics set forth in the "American Text-Book of Gynecology"; it is intended also to be used as lecture notes. The work is of the same style as Senn's "Syllabus of Surgery."

**The Twelfth Annual Report of the State Board of Health of Indiana for the Year 1893.**

This report, besides giving an official account of the sanitary work of the year, describes in detail the progress of the smallpox epidemic at Muncie and the measures taken to prevent its spread. Cuts and descriptions of the hospitals built for the reception of smallpox patients are given, and the volume concludes with a list of the physicians of the State.

**The Retrospect of Medicine; a Half-yearly Journal** containing a Retrospective View of every Discovery and practical Improvement in Medical Science. Edited by JAMES BRAITHWAITE, M.D. Lond. Vol. cx. July-December, 1894. (Issued January, 1895.) London: Simpkin, Marshall, Hamilton, Kent & Co. Ltd. Pp. 438. Cloth.

The title sets forth fully what Dr. Braithwaite assumes to accomplish. While the work is a valuable one, for the abstracts it gives are always interesting and instructive, it is far from complete, nor could a work give a complete abstract of the discoveries and improvements in medical science within the limits of 400 pages, and it is painfully apparent that the venerable editor draws from an extremely limited exchange list for a journal with such ambitious professions.

**Notes on the Newer Remedies; Their Therapeutic Applications and Modes of Administration.** By DAVID CERNA, M.D., Ph.D. Second Edition, Enlarged and Revised. Pp. 253. Cl. Philadelphia: W. B. Saunders. 1895. Price, \$1.25.

This little book, which is dedicated to Prof. Horatio C. Wood, of Philadelphia, has a great field of usefulness. The newer remedies are described by the medical press as they are reported, from time to time, and occasionally mentioned in case reports, but the author has here gathered them together in one volume, and briefly given a definition, an account of the physical properties, solubility, physiologic action, therapeutic application and dosage of each. We are pleased to note that the decimal system of dosage has been employed. In most cases both the British and the metric dose is given. The volume is a useful one and should have a large distribution.

**Medico-Chirurgical Transactions.** Published by the Royal Medical and Chirurgical Society of London. Vol. LXXVII. London: Longmans, Green & Co. 1884.

This volume, one of the most interesting of its series, contains besides the usual lists, and proceedings, twenty papers as follows:

1, Diseases of many Joints probably of Syphilitic Origin,

by Anthony Bowlby; ii, A Case of "False" Disseminated Sclerosis due to Measles, with Remarks on the Occurrence of certain widespread Nervous Disorders after This and other Infectious Diseases, by Dawson Williams; iii, On Disseminated Fibrosis of the Kidney, by W. Ainslie Hollis; iv, Arthrectomy of Elbow and Ankle, by H. H. Clutton; v, On Albuminuric Ulceration of the Bowels, by Howship Dickinson; vi, Abdominal Section for Intestinal Obstruction due to Hydatids, by J. Hutchinson; vii, On the So-called Spontaneous Disappearance of Solid Abdominal Tumors, Three Cases, by J. Greig Smith; viii, Nerve Stretching and Splitting, by Kenneth McLeod; ix, Two Cases of Intussusception of Large Intestine reduced by Introduction of the Hand into the Rectum, by Thomas Bryant; x, Case of Pleurisy caused by Pneumococcus, by J. W. Washbourne; xi, Ruptured Gastric Ulcer, Laparotomy, Recovery, by Thomas H. Morse; xii, Case of Resection and Immediate Suture of Intestine which had been Strangulated Eighty-one Hours, Recovery, by C. B. Lockwood; xiii, Persistence of the Thyreoglossal Duct, . . . by H. E. Durham; xiv, Case of Extra-peritoneal Vesical Hernia, by Ernst Michels; xv, An Operation for the Cure of Cleft of hard and soft Palate, by N. Davies-Colley; xvi, Case of extreme Prolapse of Female Urethra in a Child aged 6, by Thomas Bryant; xvii, Two Cases of Uretero-lithotomy, by Edward Cotterell; xviii, Influence of different Soils on the Comma and Typhoid Organisms, by R. Dempster; xix, Review of Cases manifesting Pain at the Heart or morbid Acceleration of Heart's Contraction subsequent to Influenza, by A. E. Lanson; xx, Case of Acanthosis Nigricans, by Malcolm Morris. Rarely has any volume of transactions contained so interesting a series of papers.

## SELECTIONS.

**Sublimophenol.**—By bringing together equal molecules of mercuric chlorid and potassium carbolate and gently heating the solution, a brick-red precipitate, which passes through yellow to white, forms, consisting of a mixed chlorid and carbolate of mercury. This has been termed sublimophenol. Washed, dried, and dissolved in boiling alcohol it forms, on cooling, colorless crystals.—*Western Druggist*.

**Delicate Reaction for Morphin.**—Lama describes (*Apoth. Zeit.*) the following reaction as detecting 0.000005 gram of morphin: A few drops of the solution are placed in a porcelain capsule, with an equal quantity of uranium acetate solution (0.03 gram uranium acetate and 0.02 gram sodium acetate in 10 cc.). A brilliant red color results at once. Oxymorphin gives the reaction as well as morphin.—*Western Druggist*.

**Toluol-Iron Mixture for Diphtheria.**—Loeffler reports brilliant results (*Deut. Med. Woch.*) from the topical application in diphtheria of ferric chlorid and toluol. He publishes the following formulas: 1, dissolve 10.0 g. of menthol in sufficient toluol to make 36.0 cc. then add 60.0 cc. of absolute alcohol and 4.0 cc. of solution of ferric chlorid; 2, menthol 10.0 g., toluol to make 36.0 cc., absolute alcohol 62.0 cc., creolin 2.0 cc. The second formula is a substitute for the iron mixture. Menthol is added to reduce the pain. A small wad of cotton is saturated with the mixture and pressed firmly against the membranous plaques, repeating every three or four hours. The false membranes begin to soften and will soon separate in large patches.—*Western Druggist*.

**Tellurium in Bismuth Salts.**—P. Janzen calls attention (*Apoth. Zeit.*) to the frequent presence of tellurium in bismuth salts, which, with Bettendorff's test for arsenic, may lead to erroneous conclusions. While the possible presence of tellurium or selenium is well understood, yet not one Pharma-

copœia has introduced tests for their detection. Commenting on Perleberg's communication the *Pharmaceutische Rundschau* reminds its readers that the alliaceous bismuth-breath is referred to, and ascribed to arsenic or tellurium by Hansen in Liebig and Woehler's "Annalen" for 1853, by Woehler and Gmelin before that date, in Blyth's "Chemistry" of 1879, by Squibb in "Ephemeris" for 1883, and others. While it is not known that the presence of minimal quantities of tellurium is injurious, the writer of this knows from experience that it is decidedly unpleasant, since for years he has been accused by acquaintances of having indulged in the strong-flavored garlic every time he had taken bismuth subnitrate for longer than one day.—*Western Druggist*.

## PUBLIC HEALTH.

**New York City Board of Health.**—A New York paper, the *Sun*, calls attention to the peculiar formation of the Board of Health of that city—peculiar in that, unlike the other municipal departments, three of the four Commissioners are chosen, not as Commissioners solely of the Board which they help to compose, but because they also hold other positions. The Board consists of four members; one, a civilian, the President, is appointed as other municipal Commissioners are, by the Mayor. The first of his colleagues is the Health Officer of the Port, who is appointed by the Governor of the State, with the assent of the State Senate. The next of his associates is the President of the Board of Police Commissioners. In his case the appointive power is the Police Board. Thus one of the Commissioners takes his appointment from the Mayor, one from the Governor, and the third from the Police Board. There is still a fourth member of the Board of Health appointed by the Mayor, but subject to the limitation that he must be a practicing physician. In effect, there are two physicians and two laymen in the Board. Another peculiarity about the Board of Health is the fact that only two of its four members receive any salary as such, and that the two who are paid get different salaries, one (the civilian) receiving \$5,000, the other (the physician) getting \$4,000.

**Does Disinfection Disinfect?**—After a series of experiments with a 2 per cent. solution of the mercuric chlorid, M. Laveran concludes that disinfection by spraying, as frequently performed, does not suffice to destroy infectious germs. In presenting the results of his experiments to the Paris Academy of Medicine he urged that the walls of an infected room should be treated as a surgeon treats his hands before an operation. That is to say, they must first be washed with soap and then with an antiseptic solution, and he recommends the successive use of a 5 per cent. solution of carbolic acid and a 2 per 1,000 solution of sublimate. In order to make this form of disinfection practicable, all rooms exposed to frequent infection—hospitals, barracks, hotels, asylums and workshops—should be made with impermeable walls. M. Dujardin-Beaumetz replied to M. Laveran by recalling the very reassuring fact that during the two years in which the public service of disinfection had been working in Paris, local house epidemics have all been promptly checked. This practical test is sustained by the experience of sanitarians in this country where the methods of disinfection in the large cities are substantially the same as in Paris and where results are obtained which are certainly, as Dujardin-Beaumetz says, "very reassuring."

**The Typhoid Oyster.**—That veteran sanitarian, Secretary Lindsley, of the Connecticut State Board of Health, must derive no little amusement from the promptness with which his discovery of an etiologic relation between typhoid

fever and the oyster has been followed up by his British colleagues in public hygiene. Sir William Broadbent, Sir Peter Eade and a host of others of lesser note are flooding the English journals with instances of oyster-typhoid, suggestions of remedy and of protection of "our succulent friend from deleterious contamination," etc. And now comes Sir Charles A. Cameron, Medical Officer of Health for Dublin, with a claim of priority of discovery. It appears that some fifteen years ago Sir Charles read a paper on "Typhoid from Oysters," which "seemed to amuse but not to instruct" his hearers; since then, he says, the "possibility of the *materies morbi* of enteric fever and of other diseases gaining access to oysters has frequently been discussed, and I have published the cases of a large number of persons who were undoubtedly subjected to severe gastro-enteritis as the result of eating oysters which were undoubtedly fresh." At best, however, Sir Charles and the other titled and untitled gentlemen have only shown that, because oysters were found in sewage and sewage in oysters, and because the typhoid poison is sometimes found in sewage, therefore the oyster might be the vehicle for conveying the poison to the small intestines of its host. But they have failed to show that what might happen really did happen in any specific instance. It remained for our own Dr. Lindsley to demonstrate such an occurrence in the case of the Wesleyan College students.

**Contagious Diseases.**—The general death rate for the month just closed has been swollen by the mortality from phthisis, pneumonia and bronchitis, the usual seasonal prevalence and mortality of which have been materially increased by the remarkable and sudden variations of temperature which have occurred in almost all sections of the country. Aside from this the general morbidity of the month presents no unusual features. The incidence of the contagious diseases remains about stationary, except as to smallpox, which, considered as an epidemic, seems to have passed its culmination. The largest number of cases of this disease is reported in Chicago, where there were 183 new cases up to the 30th ult., and a total of 268 treated—including 84 remaining in hospital at midnight Dec. 31, 1894. Of this number 98 were discharged, recovered, 42 died, 127 remaining; mortality rate 15.6 per cent. In the State at large Dr. J. W. Scott, Secretary of the Illinois State Board of Health, reports cases at and near Byron, Ogle County, at Sycamore, DeKalb County, at Harper, Ogle County and at Desplaines and Kirkland, Cook County. Dr. Wingate, Secretary of the Wisconsin State Board of Health, reports, for the week ended January 26, six cases, no deaths, at Appleton (confined to two houses and under control); two cases, one death at Two Rivers; five cases, one death in Gibson Township; five five cases, two deaths at Mishicot; one case, no death at Manitowoc Rapids; one case, no death in Franklin Tp.; six cases, five deaths in Milwaukee. Total number of cases on hand in Milwaukee, fifty-four; in hospitals, sixteen, in homes, thirty-eight. The JOURNAL is unable to learn the exact status of the disease in Detroit. A newspaper dispatch of the 26th ult., reports some sixty cases on hand, two-thirds being treated at homes. It was also stated that Dr. McLeod, the Health Commissioner, has tendered his resignation to take effect on the 15th prox.; that the position had been tendered to Dr. G. W. Stoner, U. S. M. H. S., who had declined, whereupon it was offered to Dr. W. H. Hutton, U. S. M. H. S., who had accepted, subject to the approval of the Supervising Surgeon-General of the Service. Influenza is slowly increasing the area of its invasion, but, except in New York City, has thus far exerted no marked effect upon the death rate except as it may have increased the mortality from pneumonia when it occurs as a complication of this latter disease. There have been, however, a number of "sudden deaths—cause not rated" among middle-aged and elderly persons who were afflicted with the disease two or three years ago.

## SOCIETY NEWS.

**King County (Seattle, Wash.) Medical Society** has elected the following officers for the coming year: President, L. R. Dawson; Vice-President, W. T. Sloan; Secretary, F. B. Whiting; Treasurer, Geo. M. Horton.

**Hampden District Medical Society.**—The quarterly meeting of the Hampden District Medical Society was held in Springfield, Mass., January 15.

**Brainard District Medical Society.**—The quarterly meeting of the Brainard District Medical Society was held in Jacksonville, Ill., January 24.

**How It Looks to the Lay Press.**—At the meeting of the Tri-State Medical Association, at Atlanta, last October, Dr. B. read a very interesting and instructive paper, and he received requests from six of the leading medical journals of the United States to publish the same. The request was granted to the *International Journal of Surgery*, of New York, and he was complimented with 250 copies of a reprint, which is an unusual distinction accorded physicians. The article appears in the December number of the above journal.—*Chattanooga Times*, Jan. 20, 1895.

**Cleveland Medical Society.**—The Cleveland Medical Society held its annual election at its quarters in the Chamber of Commerce rooms on Friday evening, Jan. 11, 1895. The following officers were elected; President, Wm. E. Wirt; First Vice-President, Aug. F. House; Second Vice-President, H. S. Upson; Recording Secretary, W. F. Brokaw; Corresponding Secretary, F. S. Clark; Treasurer, N. Stone Scott; Librarian, Wm. E. Bruner; Censors, M. Rosenwasser, H. S. Straight, L. B. Tuckerman, A. J. Cook, W. J. Scott; Pathologist, A. P. Ohlmacher; Trustees, H. G. Sherman, Chas. Gentsch, C. F. Dutton.

Immediately after the election the Society adjourned to the Hollenden Hotel where the annual banquet was held. The retiring President, Dr. W. H. Humiston, stated in his address that the Society has 291 members; that the average attendance for the year was 135, being in this regard second to no society of its kind in the United States, as shown by reports he had received from other societies. The Society meets every two weeks.

## NECROLOGY.

ALFRED L. LOOMIS, M.D., of New York, Jan. 23, 1895. Professor Loomis had been ill since Sunday with acute pneumonia. Was born in Bennington, Vt., 63 years ago, and was graduated from Union College in 1851 and from the College of Physicians and Surgeons in 1853. After his final graduation he served for two years as a member of the medical staff of the Ward's and Blackwell Islands hospitals. Then he engaged in private practice and soon became a recognized authority on pulmonary diseases. He became the visiting surgeon at several hospitals and public institutions. From 1862 to 1865, inclusive, he was a lecturer in the College of Physicians and Surgeons, after which he was made Professor in Medicine of the University of the City of New York. In 1867 he was made a Professor of Pathology of the same institution. Through an admirer he was placed in charge of a fund of \$100,000 with which to build a laboratory in the same university, to be named after himself.

Dr. Loomis became a member of many medical societies and associations, and at his death he held a number of honorary degrees which had been conferred upon him. He was the author of a number of medical works, and may be said to have been one of the most popular physicians in the great city.

Dr. Loomis was twice married. Two children and a widow survive him. The funeral was held at the Church of the Incarnation at Madison Avenue and 35th Street, on Saturday, January 26.

JOHN YOUNG MCGAY, M.D., died Oct. 12, 1894, aged 40 years. He was a native of New York City, the son of Mr.

Robert T. McGay. He was educated in that city, taking his medical diploma in 1880, at the Medical Department of the New York University. At the time of his decease he was temporarily residing at Lisbon Centre, St. Lawrence County, N. Y. His fatal malady was chronic nephritis.

FOUNTAIN N. TALIAFERRO, M.D., of Hicksville, Long Island died January 16, aged 34 years. His death took place at Aiken, S. C., to which place he had gone several weeks ago for the benefit of his shattered health. Dr. Taliaferro was a native of Virginia, but he had been a resident of New York since the time of his graduation in medicine, which was from the University of New York, in the class of 1889. He was health officer of his township for one term, and had built up a very desirable practice.

E. F. SHORB, M.D., of Laurel, Md., January 15, aged 69.—Wm. Wood, M.D., of Grand Rapids, Mich., January 14, aged 56.—G. W. Topping, M.D., of De Witt, Mich., January 14, aged 67.—J. W. Hicks, M.D., of Orlando, Fla., January 14.—Mary W. Noxin, of New York, January 16, aged 40.—W. A. McCully, of Independence, Kansas, January 22.—Francis C. Neale, of New York, formerly of Baltimore, Md., January 17, aged 60.—John Powell, M.D., of Pennsylvania, in Zacatecas, Mexico, January 28.—Robt. Lee Long, M.D., Mexia, Texas, January 20.—Henry A. Archer, M.D., at Meriden, Conn., January 20, aged 74.—W. O. Kulp, M.D., Davenport, Iowa, January 12, aged 59.—J. E. White, M.D., Toronto, aged 47.—Geo. C. Pease, M.D., Kalamazoo, Mich., January 25, aged 50.—Jas. Strong, M.D., Cleveland, January 29.—M. T. Trovinger, M.D., Hornelltown, Ohio, January 23, aged 35.

## MISCELLANY.

**Wisconsin State Board of Health.**—At the annual meeting of the Wisconsin State Board of Health, Dr. J. W. Hancock, of Ellsworth, was elected President for the ensuing year.

**Dr. E. E. Hegg,** of North Yakima, Wash., has been appointed a member of the Washington State Board of Health and Bureau of Vital Statistics.

**Dr. R. S. Bragg,** of New Whatcom, Wash., died January 21 from rheumatism of the heart. He was one of the leading physicians of his county, an ex-President of the County Medical Society, prominent in Masonic and Odd Fellow circles, and a director in one of the city banks.

**Can Not be Sent by Mail.**—Bacteriologists and pathologists should take notice that by the new postal regulations, "disease germs and matters from diseased persons" are unmailable matter, and can not in the United States be sent by post.

**Charbon in Sicily and Sardinia.**—The malignant pustule rages with persistence in Sicily and Sardinia. From January to October, 1894, there were sixty-six cases of charbon in the province of Palermo. Experiments are being made in Italy to popularize anti-charbonous vaccinations and vaccinations on a large scale in the contaminated countries.—*Gazette Médicale de Liège*.

**The Quarter Century Medical Club,** for social, biographical and historical purposes, was organized in Detroit, Mich., January 15. The qualifications for membership are twenty-five years' practice in Detroit and good standing in the profession. The following officers were elected: President, Peter Klein, M.D.; Vice-President, E. W. Jenks; Treasurer, Hamilton E. Jmth; Secretary, J. J. Mulheron.

**A Bengalese Superstition.**—A paper, read before the Anthropological Society of Bombay, contains a long list of senseless superstitions that thrive in the Hindoo mind. There is one of them that has sufficient interest to quote before a medical audience, namely: "Do not wake up a sleeping

physician." Comment is hardly necessary, but the saying will inevitably call to mind the Anglo-Saxon adage about "letting the sleeping dog lie." The parallelism does not speak well for the popular esteem of the native Hindoo physician.

**Cologne Tippling.**—According to *L'Union Médicale* this habit is increasing. Alcoholics, especially women, begin by taking a few drops of *eau de cologne* and finally drink it by the glass. The writer seems to think this form of alcoholism may replace or cure the cocain and morphin habits. The habit is exceedingly injurious, for in addition to the poorly rectified alcohols are the natural or artificial essential oils which are equally toxic. The practice is found among the upper classes principally.

**Extirpation of the Stomach of a Cat.**—At a recent meeting of the Paris Biological Society reported in the *Gazette Médicale de Paris*, M. M. Parchon and Carvallo exhibited a cat from which they had removed the stomach, and they detailed the results of the operation. The general nutrition was normal, the three species of foods—albuminoids, carbo-hydrate and fats were well digested; the digestion of milk, however, was faulty. The animal thrived best on a pap of milk, rice flour and yolk of an egg. Croked meat was perfectly digested, raw meat imperfectly. Professor Dasht observed that we know the gastric juice produces changes in meat similar to those from cooking.

**Dr. Daniel Lewis.**—Dr. Daniel Lewis, of New York City, has been nominated by Governor Morton to be a member of the State Board of Health. Dr. Lewis was born in Allegany County, New York, Jan. 17, 1846. He studied at the Alfred University, after serving in the Navy throughout the Civil War. Graduating in 1869, he studied medicine in the New York College of Physicians and Surgeons, taking his degree in 1871. When the New York Skin and Cancer Hospital was established, Dr. Lewis was appointed to a junior position on its staff of which he is now the head. He also occupies the chair of Special Surgery in the Post Graduate Medical School. Dr. Lewis was elected President of the County Medical Society in 1884 and reelected a year later. He was elected President of the State Medical Society in 1889.

**May Give Opinions as to Cause of Disease.**—The rule is well established that an expert witness, in giving his opinion, must first state all the facts upon which he bases his opinion. But after a physician has testified fully as to examinations he has made of a patient, the condition in which he found the latter, detailing also to the jury what he learned from the patient, the Appellate Court of Indiana, in *Louisville, N. A. & C. R'y Co. v. Holsapple*, a case decided Nov. 22, 1894, holds that the witness may give his opinion of the cause of the patient's maladies, as for example what caused an unnatural growth in her womb. So also does the court hold that where a medical expert has testified fully as to the examinations made by him, he may state whether, in his opinion, the injuries as he found them are temporary or permanent.

**Treatment of Gonorrhea.**—Dr. H. M. Christian (*Therapeutic Gazette*) claims that irrigation of the urethra with potassium permanganate, 1 to 4,000, doubled in strength the second week, is the best remedy for simple non-infectious urethritis. The irrigations are made daily with about one quart of a warm—not hot—solution, the patient standing and the reservoir at a height of six feet. A cure can be effected in from ten to twelve days. This can not be solely relied on for a specific urethritis, but to a certain point he considers irrigation the proper treatment—relieving *ardor urinae* and chordee promptly and largely preventing such complications as total urethritis and epididymitis.

**Prophylaxis of Malaria.**—A commission of the Therapeutic Society of Paris, consisting of Mm. Adrian, Bardet, Berlioz and Boymond, appointed for the purpose, have reported on the best forms of quinine to administer for the prophylaxis of malaria. As a general rule: Solutions of the salts of quinia should be reserved for active attacks; compressed preparations are condensed. Preference is given to pills made up with a soluble extract or to *perles* provided with a gelatinous envelope. The basic hydrochlorate is pronounced the best prophylactic salt—richest in alkaloid; sufficiently soluble; less irritant to the stomach than the sulphate. The hydrobromate may be substituted where there is intolerance of the hydrochlorate. Doses of 15 centigrams, night and morning, suffice to maintain the prophylactic effect during exposure to malaria.

**Charlatanism in Bavaria.**—From recent official statistics furnished by the Bavarian government in 1893, *L'Union Medicale* has compiled the following data: There were 1,152 persons in that country practicing medicine illegally—832 men and 320 women. In 1892 the number was 1,184, the diminution being in the men alone. As regards nationality, 1,097 were natives, 32 from other parts of Germany; 19 were Austrians, 2 Americans, 1 Italian, and 1 Swiss. Their previous occupations had been—pharmacists, 322; medical students, 2; widows of physicians, 2; bath assistants, 4; day laborers or peasants, 219; clerks, 12; salaried officials, 57; ecclesiastics, 22; religious, 2; workmen, 188; merchants, 49; professors, 6; writers, 6; masseurs, 10; annuitants, 44; widows of veterinary surgeons, 2; ditchers, 2; of unknown occupations, 52; the rest scattering. The branches of the healing art to which these individuals applied themselves were medicine generally, 333; sale of drugs, 207; intestinal worms, 6; surgery, 70; diseases of women and children, 21; electro-therapeutics, 14; fractures and dislocations, 21; secret remedies, 118; jaundice, 1; obstetrics, 43; massage, 4; homeopathy, 87; hydropathy, 13; magnetism, 6; internal medicine, 71; "natural" medicine, 10; diseases of the eye and ear, 9; uroscopy, 5; hernia, 1; wounds and ulcers, 34; dentistry, 10, etc.

**Disinfection of Catheters.**—Dr. John Ward Cousins in the *British Medical Journal*, Jan. 19, 1895, recommends a steam apparatus for the disinfection of metallic and other catheters. It is well known that boiling is not a good way to cleanse soft catheters, and that the insides of metallic catheters can not be satisfactorily cleaned by the ordinary method. Dr. Cousins' apparatus consists of a boiler having a capacity of about three pints and capable of bearing a pressure of eighty pounds to the square inch. It can be heated by a spirit or gas jet in about fifteen minutes. The steam pipe is connected with a circular tube fitted with projecting terminals, and these are adapted to hold a complete set of catheters. An old-fashioned spray apparatus can have the circular tube attached to them if required. After the steaming a polishing stilette is introduced and the instrument carefully dried.

**Tricresol as an Intestinal Antiseptic.**—M. Hiller, of Breslau, claims for tricresol a powerful microbicidal action, destroying promptly the bacilli of cholera, typhoid fever, etc. While more potent than carbolic acid it is relatively but slightly poisonous. Thus M. Hiller found it feasible to give  $1\frac{1}{2}$  or 2 grams for several days in succession, encased in gelatin capsules, containing each 10 centigrams of tricresol. M. Koelsch, of Newstadt, reports a series of twelve cases of typhoid fever treated with tricresol, to the exclusion of everything else, even baths. The patients took the remedy three times a day, half an hour or an hour after their milk or bouillon, according to the following plan: Three capsules the first day, 6 for the three following days, 9 for the next three days and 12 for the next three; from the eleventh day on, the daily quantity of capsules was gradually diminished in an inverse ratio. Koelsch claims that

the patients treated in this way showed less tympanism and sensitiveness of the abdomen, and there was a total absence of complications and relapses. The six patients who were treated by this method from the beginning of the complaint—that is to say, from the third to the seventh day—reached a convalescent state in about the same length of time for the whole number of cases, a period that only varied between thirteen and seventeen days. It is reported that in these cases the favorable effect of the tricresol was most evident; this appeared generally as soon as six capsules a day were administered, though sometimes not until twelve were given and its chief sign was a gradual lowering of the temperature until it fell to the normal.

**Thumbs Bring \$2,000.**—The case of Kitchell v. Brooklyn Heights Railroad Company, was instituted to recover damages for the loss of services caused by the amputation of the thumb of a 7-year-old daughter of the plaintiff. Liability therefore was charged to the company sued on account of its negligence causing the injury which resulted so disastrously. A verdict for \$2,000 was returned, and the general term of the city court of Brooklyn holds, Nov. 27, 1894, that, considering the importance of the thumb as a member of the hand, and how necessary its presence is to make the hand available for use in nearly all ordinary vocations, this is not excessive, a bill of \$100 for medical treatment having also been incurred.

**Limit to Liability for Injuries Resulting in Miscarriage.**—The courts are experiencing considerable difficulty in keeping questions of sentimental damages out of personal injury cases. In Tunncliffe v. Bay Cities Consolidated Railway Company, decided Dec. 7, 1894, the Supreme Court of Michigan holds that while in such an action, brought for the recovery of personal injuries sustained by a married woman resulting in her miscarriage, the jury is allowed to consider the case with all its facts, and to take into account, for the purpose of a consideration, not only the physical pain, but also mental suffering, in determining the award of damages and while, of necessity, this involves to some extent a consideration of the nature of the injury, and can not exclude from the consideration of the jury the fact that the physical and mental suffering of the mother by reason of such an injury would be more intense than in the case of an ordinary fracture of a limb, yet beyond this it would not be competent for the jury to go, and to attempt to compensate for the sorrow and grieving of the mother. This seems to be the general conclusion of all the courts.

**Decision on New York's Pharmacy Law.**—In 1893, at the same session of the New York Legislature, there were two acts passed—one on March 31, and the other May 9. The first (Chapter 250, Laws of 1893) provided, in substance, that where a person was entitled to a license under the provisions of the act of 1884, but who had failed within ninety days to apply to the board of pharmacy for a license, he might, upon giving not less than eight days' notice to the secretary of the board of pharmacy, apply to the Supreme Court for an order directing the board to issue said license, and granting the court power to grant such order upon proof of good and sufficient cause shown for the neglect to apply for such license in due time. The other (Chapter 661 of Laws of 1893) made provision for a State Board of Pharmacy, and for the licensing of pharmacists. Under it there are two classes of persons who are entitled to a license to practice pharmacy,—those who have had four years' experience in the practice of pharmacy, prior to Jan. 1, 1893; and those who hold certificates of designation as pharmacists by examination from any board of pharmacy legally created under the laws of the State. The Supreme Court of New York, special term, Albany County, holds (*In re Ward*), Oct. 30, 1894, that this latter act was evidently intended to take the place of all statutes theretofore passed in relation to those matters, and by it Chapter 361 of the Laws of 1884 was expressly repealed; and, the whole of said act being repealed Chapter 250 of the Laws of 1893, being an amendment to a single section thereof, fell with it.

	An amiable family.
65	Universal respect.
	Consciousness of a virtuous life.
	Perfection of earthly happiness.
70	Preparation for eternity.

The foregoing was the plan of Sir William Jones for the life of an English gentleman. With some variations it may be taken for any gentleman of another profession than that of law.

**Skin Diseases in the German Army.**—In one year, according to Antony (*Arch. Med. Milit.*) there were 89,845 cases of skin disease in the German Army—or 214.5 per 1,000 of total strength; 2,000 of these were scabies. In November, when the new recruits arrive, the cases of scabies increase markedly. The use of corrosive sublimate solution often causes the appearance of eczema. At Wiesbaden a case of general psoriasis was observed as the sequel of scarlatina. The use of one-tenth chrysarobin ointment is an excellent remedy for psoriasis, but symptoms of intoxication sometimes follow; these symptoms are usually gastric catarrh, rapid emaciation, ocular catarrh and coloring the hair white or red. A total of 23,565 men were treated for phlegmons and excoeriations and 31,029 for furuncles. The treatment of furuncles with interstitial injections of carbolic solution—1 to 100—gave very variable results; as the result of numerous obser-

vations it is found that this mode of treatment is indicated when the furuncle has fully developed, but before pus has formed; unfortunately, the injection is extremely painful. Whitlow afflicted 10,387 soldiers, and two cases of pyemia and one of abscess of the thigh resulted.

**Strontium Salicylate.**—Dr. H. C. Wood, in common, as he supposes, with most practitioners, has for many years been trying to find some way of getting the general action of salicylic acid without the gastric disturbance which so often follows the exhibition of its salts of sodium and potassium. In the current number of the *University Medical Magazine* he describes a salicylate of strontium which he has had prepared and employed in a large number of cases in quantities of from 15 to 120 grains a day. In doses of 5 to 10 grains, given after meals, the salt very commonly improves digestion and in the dose of 5 grains an hour after meals in flatulent dyspepsia and various conditions of tendency to fermentative changes in the alimentary canal, it is a useful intestinal antiseptic, seeming to him to give better results than do salol, naphthol or other of the older antiseptic remedies. It has not yet been tested in acute articular rheumatism and Dr. Wood thinks it would probably be less efficacious in this disease than the ammonium salicylate; but in muscular or subacute rheumatism with a tendency to digestive disturbance he has found it a very valuable remedy, exerting the action of the salicylates upon the diathesis and improving instead of injuring the digestion. It may be given in solution, but is best administered in 5 grain capsules. In his preliminary experiments on the lower animals, undertaken to determine the influence of this salt on the circulation, Dr. Wood found that the dose of the strontium salicylate necessary to lower arterial pressure was nearly twice that of the sodium salicylate and distinctly more than that of the ammonium salicylate.

**Life-Maintaining Dietary in Central Africa.**—Lieutenant Lemaire, an officer of the Congo Free State, has written in the *Independence Belge*, on the improved health of foreigners dwelling above Stanley Pool, that has followed the larger use of the fresh vegetable products of the country. These vegetables are sufficiently varied, but they are so different from the accustomed food of Europeans and Americans that they do not at once find a welcome to their table. But they are soon found to be much more conducive to health than the imported canned goods, that can seldom be made to "keep" properly under the African tropics. M. Lemaire remarks upon the low rate of mortality among the whites upon the Upper River, as it is called; he seeks to explain the good health of certain of the missionaries as due in part to a plentiful amount of physical exercise, and in part to their adopting the food supplies that are native to the region. He says: "We have never seen an excess of manual labor bring on fever or any sort of indisposition. During my stay at the equator, from December, 1890, to June 19, 1893, not one of the white personnel of the station died, save a Danish mechanic who came to us only to take his bed. The best illustration that I can give is that of the American Protestant Mission carried on by the Rev. Charles Blair Banks and his wife, who have lived there seven years, and have had three children born there who are surprisingly healthy. The result is due to the fact that Mr. Banks, having built a charming cottage in the midst of a real park, has used the resources of the country for the larger part of his food supply—fresh vegetables from his garden, instead of canned peas, and, in general, fresh poultry and mutton instead of preserved meats—fresh goat and sheep milk instead of condensed milk, and the abundant fruits of the country instead of canned preserves."

**Uniformity in Medico-Military Statistics.**—The International Commission of Military-Medical Officers for uniform sanitary statistics which met at Buda-Pesth in September last, Dr. John S. Billings, U. S. Army, chairman, came to an agreement as to the character of the statistics to be published for comparative purposes by each of the countries participating

in the convention. The Secretary of the Commission, Dr Myrdacz, of Vienna, has been informed by certain members of the Commission of the continuation of their status as members by authority of their respective war departments. These include Drs. Pillsbury, of the U. S. Army; Notter, of the British Service; Griesheim, of Berlin; Dziewonski, of Paris; Von Harten, of Copenhagen; Van der Straten, of Brussels; Sforza, of Florence; Hermann, of Ingolstadt; and Myrdacz of Vienna. A series of ten international statistical tables have been issued for the consideration of the various military medical departments and for adoption by them, if approved. These have been submitted to Surgeon-General Sternberg and it is probable that in his next annual report will be embodied the first issue of the international statistics. Table 1, provides for the data gathered by the recruiting service; 2, and 3, for the sickness and mortality in the various military departments; 4, sickness as prevalent in the various corps and arms of the service, and by months; 5, sickness as distributed among the larger garrisons; 6, and 7, specification of the prevalence of the most important diseases in absolute numbers and in rates per thousand; 8, distribution of the important diseases among the different corps and arms of the service; 9, monthly prevalence of the important diseases; and 10, deaths from disease, suicide and accidents or injuries according to years of service and age. The important diseases of the international nosological table comprise thirty-three titles which include most of the specific febrile and acute infectious diseases with alcoholism, gonorrhea, hernia, sunstroke, scurvy, syphilis, trachoma, tuberculosis of lungs and of other organs, and diseases of the eye, ear, mind, heart, skin and genito-urinary system.

**Barrack Room Floors to be kept Dry.**—A few years ago it was the custom in the Army to scrub the floors of all barrack rooms every Saturday afternoon, preparatory to Sunday morning inspection when every man and all his belongings and intimate surroundings were expected to be at their cleanest and best. Saturday thus became a day of discomfort in quarters at all times and of danger to health in inclement seasons. The men detailed for the duty of scrubbing, scrubbed no doubt efficiently to remove stains when present, but as these were not usually allowed to disfigure the floor from one day to another the weekly cleaning up became often a perfunctory flushing with water and the removal of the wash water by the readiest possible way. The use of wax and turpentine, paraffin and benzin and other methods of filling up the pores of the wood and rendering the floors impermeable to water began in the wards of the post hospitals and has gradually been extended to other barrack rooms. The reports of the Surgeon-General called attention to this point in domestic sanitation some time ago and General Miles appreciating the suggestion has directed its adoption by post-commanders in the Department of the East in General Orders No. 5 Jan. 19, 1895, which read as follows:

"In cleaning the floors of barracks, dormitories, dining halls and other occupied rooms, post commanders will see that action is taken in accordance with the following recommendation of the Surgeon-General of the Army:

"Some medical officers in their reports call attention to the practice of flushing the floors of quarters, dormitories, dining halls, and other occupied rooms. At many posts this method of cleaning up is regarded as an indispensable preliminary to inspection of quarters. It has long since been given up in the Navy on the sanitary principle that a damp ship is an unhealthy one. The same principle applies to barrack rooms. It is important that the soil beneath the flooring should be kept as dry as possible, and this can not be effected if water is flushed on the floors and permitted to run through open seams or broomed into knot holes or auger holes, specially bored to permit of this method of disposing of the wash water. One medical officer, in view of such practices, felt called upon to report to his commanding officer that:

"The barracks having been for the most part newly floored during the month, I recommend that positive orders be given that no auger holes be bored through these floors for the purpose of allowing water that has been used for cleaning purposes to escape beneath them."

"Another medical officer states that he has served at posts where the men had the alternative of staying in quarters with a thoroughly wet floor, or going out of doors with two feet of snow on the ground and the thermometer at zero. As catarrhal and rheumatic affections are prone to be developed by flushing, commanding officers should prohibit the practice. Floors when lightly stained and waxed can be kept clean, dry and wholesome."

### Hospital Notes.

**NEW HOSPITAL FOR THE INSANE.**—The Sisters of Mercy have decided upon the erection of a new hospital for the insane at Asbury, Iowa.

**PRESBYTERIAN HOSPITAL.**—The Presbyterian Hospital, at Milwaukee has been incorporated with a capital of \$8,000.

**EYE, EAR AND THROAT CHARITY HOSPITAL.**—The annual report of the Eye, Ear and Throat Charity Hospital of Baltimore, Md., shows that 11,750 were treated during the past year.

**A MATERNITY HOSPITAL** will be erected in Syracuse, N. Y., on the site of the building destroyed by fire over a year ago.

**WOMEN'S AND CHILDREN'S HOSPITAL ASSOCIATION.**—The Women's and Children's Hospital Association have applied for a loan of \$13,000 to begin the work.

**AURORA (ILL.) HOSPITAL.**—The annual report of the Aurora (Ill.) Hospital shows that 1,000 patients have been treated during the year.

**LYING-IN HOSPITAL.**—The new Lying-in Hospital of the City of New York was formally opened January 16.

**NEW YORK POST-GRADUATE MEDICAL SCHOOL.**—The directors of the New York Post-Graduate Medical School and Hospital met January 17, and elected the following officers: President, D. B. St. John Roosa; Vice-President, George Henry Fox; Secretary, James L. Skillin.

**DR. PERCY BRYAN** has been appointed first assistant physician in the Buffalo State Hospital.

### Louisville Notes.

**MORTALITY REPORT.**—There was a total of seventy-eight deaths during the past week. There were fifteen deaths from pneumonia, and ten stillbirths in the number.

**FOR THE STATE SENATE.**—Dr. A. D. James, a Muhlenberg county physician, recently announced himself as a candidate for State Senator from the District composed of Butler, Ohio and Muhlenberg. The candidacy of Dr. C. J. Walton for State Auditor was recently announced through these columns.

**CITY HOSPITAL.**—Once more the hospital is in the hands of an "Investigation Committee" from the City Council. The present investigation seems to have arisen because of a personal difficulty between a member of the council and one of the contractors whose bill has not yet been paid for work done during the renovation of the hospital. The original estimate of the cost of repairing the hospital was far less than the total cost, which has amounted to \$114,963.98, and already an investigation has been made because of this. It is not apparent what good can be done by the present investigation when the claims for the work done have been approved and the bills paid, except a balance for \$800, due the contractor above referred to. It is certainly to be regretted that the money spent in repairing the old hospital had not been spent for a new building which would have done credit to the city.

**A FAMOUS KENTUCKY SURGEON.**—Dr. D. W. Yandell in his presidential address before the American Surgical Association, paid a tribute to the work of Dr. Charles McCreery, stating that it was to be regretted that more was not known of his personal and professional character. The following

## ORIGINAL ARTICLES.

### A CASE OF INFANTILE SCORBUTUS, IN MONTANA.

BY P. RALPH EGAN.

ASSISTANT SURGEON UNITED STATES ARMY.

Infantile scorbutus was first definitely described by Dr. Cheadle in 1878. This description he further supplemented by cases published in 1879 and 1882. Prior to that time these cases had been recorded as acute rickets, especially by German observers. In 1883, Dr. Barlow first established by two post-mortem examinations that the disease was true scurvy. In this country, Dr. Northrup confirmed Dr. Barlow's observations by a post-mortem made on a child dying from an indetermined disease at the New York Foundling Asylum in 1889. Since that date various post-mortem and clinical cases have placed the correctness of these views beyond dispute.

This disease is, however, comparatively rare. It occurred but once in over two thousand cases of children seen at the out-door department of Bellevue Hospital (Neubans) and not once in a thousand cases at the same department of St. Mary's Free Hospital for Children (Carr). It is, however, less commonly observed in hospitals than in private practice. In 1891, Dr. Northrup was able to collect only 11 cases; while but twelve months since, 106 cases were reported at the New York Academy of Medicine. The frequent refusal of mothers to nurse their children and the almost universal use of proprietary foods are said to account for this increasing frequency of the disease.

These proprietary foods mixed with water or condensed milk are the most common causes of the disease. Condensed milk alone, and fresh milk unduly diluted have also produced some cases. Prolonged sterilization of milk so far destroys its nutritive power as to give rise to scorbutus. It is more common among the children of wealthy parents than among those of the poorer classes. The latter are unable to procure proprietary foods, and give their children antiscorbutics from their table at an earlier age than scurvy generally develops. Hence its rarity in hospital practice.

The principal lesions occur in the femora, tibiae, scapulae, ribs and cranium. Those found on post-mortem examination by Dr. Barlow (Medico-Chirurgical Transactions 1883, Bradshaw lecture 1894) were due to extravasation of blood. This occurred between the periosteum and the shaft of the thighs. Fractures between the lower epiphysis and the shaft were found in marked cases; the periosteum was very vascular but there was no inflammatory effusion. In the interior of the bone was found evidences of rickets, and hemorrhage into the medullary canal. There was also extravasation of blood round the tibia,

which was fractured at the line of junction of the epiphysis and the shaft. The ossifying centers showed evidence of rickets. There were large extravasations of blood into the deep muscular layers of both the leg and thigh. The periosteum of the fibula was congested but only slightly detached. Extravasations surrounded the entire scapula. Anteriorly it was so marked as to produce a tumor recognizable during life; posteriorly the raised periosteum had produced a thin layer of bone. The periosteum was found detached from the ribs with a chocolate colored detritus of broken-down blood clot intervening. The ribs were quite bare and separated from their costal cartilages at the line of junction; they were found to be mere shells filled with extensive indosteal hemorrhage. The cranium showed thin extravasations in the vicinity of the petrous bone on both parietals. There were also found a subperiosteal extravasation into the eye-ball. Hemorrhages have been found in the lungs, and under the capsule of the spleen. Blood-stained serum existed in the pleurae. Hemorrhages have been noted in the mucous membrane of the stomach and intestinal canal, and rarely slight ulceration. The dark spongy, hemorrhagic condition of the gums of children with teeth is characteristic of the disease. Now that the general practitioner is becoming familiarized with its symptoms, autopsies will be exceedingly rare. Fortunately the hypodermic needle may be used to draw off some of the effused blood from around the femora in doubtful cases. Few people will risk making extensive incision and burning out the blood clots, as did Mr. Page, of St. Mary's Hospital, London.

The following case developing during the summer on the plains of Montana, amid hygienic surroundings, illustrates nearly all the clinical features of the disease:

N. F., a female born July, 1891; has nursed until 3 months old. She was then fed on Mellin's Food and condensed milk. On this diet she seemed to thrive for about nine months. At 5 months her teeth began to appear; during the next two months she cut eight, then no more showed until she was 16 months. Her meals when 9 months consisted of the following: Two tablespoonsful of Mellin's Food to one of condensed milk in one half-pint of water every three hours. She never learned to creep on all fours but when about 7 months old she used to pull herself about the floor in a sitting position, and to stand on her feet. The first indication of her illness was that she refused to move in this way, or to stand when supported. It was not noticed that she was fretful but she grew more delicate, seemed tired all the time, and unable to move her limbs. Her favorite position was with her head resting on her nurse's arm and her legs drawn up. When she was about a year old her parents went a visit to the Yellowstone National Park. While there it was noticed that her gums

were dark and swollen. The doctor in attendance did not in any way connect this swelling with her inability to move her limbs. It was considered a vascular outgrowth, which was accordingly removed and cauterized. Notwithstanding this treatment the gums continued to enlarge and bleed on pressure.

At about the same time it was noticed that her left leg was painful and that she cried when it was handled or when her shoes were put on. Soon after her right leg became similarly affected. These were considered rheumatic symptoms, and she was treated accordingly. During this time her head perspired freely and needed to be dried quite frequently. She also suffered from diarrhea throughout the summer. Her discharges were generally green and slimy; blood was passed with some of the motions, so as to give rise to the suspicion of "bleeding piles." No fever was observed at any time during her illness; neither was any change observed in the color of her urine. When the lower limb became painful the doctor did not think, from comparing it with the other, that there was any increase in size. At no period of her illness were her parents or attending physician able to note any swelling, but no accurate measurements were taken. One of the five doctors under whose observation she now passed made an attempt to change her diet to cow's milk. It was found to disagree, causing nausea and constipation, so the attempt was abandoned. The parents state that they did not understand this change to be at all essential, but simply an experiment. When she was about 16 months old I first saw her in consultation. The patient was anemic but fairly developed; the muscles, however, were soft and flabby, the hair was sparse and the head moistened with perspiration; there was no cranial tabes. The chest was well formed but there seemed to be slight beading of the ribs. The abdomen was not prominent. The legs lay helpless, were not moved, and were exceedingly tender to the touch. The thighs appeared slightly infiltrated between the knee and the hip, but were smaller in size. The arms were freely moved. There was no enlargement of any of the epiphyses and in fact no symptoms of rachitis, save slightly "beaded" ribs, and marked perspiration about the head. There were no petechiae present and no fever. The gums notwithstanding frequent cauterization, were so enlarged as almost to cover the teeth, of a dark purple color, and bled on the slightest application. The breath was foul, and the bowels relaxed.

The diagnosis of infantile scorbutus was made from the pseudo-paralysis and excessive tenderness of the lower limbs, but more especially from the condition of the gums, which was characteristic. It was apparent from the symptoms that there was little if any extravasation around the femora and tibiae. This is a condition that has been noted on post-mortem examination by both Drs. Cheadle and Sutherland. However, during convalescence and while the patient was under my immediate observation, a large subcutaneous hemorrhage was found on the thigh without known cause. Others probably occurred at an earlier date. The diarrhea—in this case complicated with blood—to which Dr. Carr has called attention was quite prominent. The "beaded" ribs and the head perspiration led me to believe that the scorbutus was complicated with a mild degree of rachitis.

The child was put on fresh milk and a rational diet suited to her age. The attending physician gave

a little lime water and cod liver oil for the rachitis. Later, when she came under my immediate care, Thompson's solution was given for the same purpose. She steadily improved and would now make a splendid picture for an advertisement, setting forth the fact that proprietary foods are always useless, and frequently dangerous.

As in the present case, infantile scurvy is usually mistaken for rheumatism. Less frequently it has been confounded with hemophilia or congenital syphilis. Even at the present time some writers, like Dr. Ashby (*Practitioner*, December, 1894) refuse to admit the existence of true scorbutus in children, and contend that it is only acute rickets complicated with anemia which gives rise to a tendency to bleed. The same hemorrhagic condition he asserts to be present in tuberculosis. Fresh vegetables are looked upon as a preventative of scurvy, but with regard to fresh food, such as meat and milk, there is, he believes, no such agreement. However, the failure of observers like Dr. Northrup to find evidence of rachitis, even in the post-mortem examination of the case which formed the base of our knowledge of the disease in this country, the rapid recovery of cases when given antiscorbutic diet and the occurrence of the subperiosteal and other hemorrhages characteristic of scurvy, as it affects the adult, will induce most observers to hold with Drs. Cheadle and Barlow that the disease as seen in children is no other than true scorbutus.

## NERVOUS DISEASE IN EARLY SYPHILIS.

Read before the Chicago Academy of Medicine, October, 1895.

BY G. FRANK LYDSTON, M.D.

Professor of the Surgical Diseases of the Genito-Urinary Organs and Syphilology in Chicago College of Physicians and Surgeons; Surgeon in charge of the Masonic Hospital of Chicago; Fellow of the Chicago Academy of Medicine; Lecturer on Criminal Anthropology in the Kent Law School; Fellow of the American Academy of Social and Political Science, etc.

Involvement of the nervous system in late syphilis is so common that all practitioners of experience have met with syphilitic nerve phenomena of varying types. Nervous disturbances occurring as a part of the clinical picture presented by the secondary or active period of the disease are much less frequent—so much so that such cases are often overlooked and even discredited as syphilitic possibilities by physicians in large practice.

Surgeons of large experience in the treatment of syphilis, with better opportunities for the study and systematic management of the disease have, on the other hand, come to regard early nerve disease in syphilis as sufficiently frequent to merit special consideration. Hutchinson and Fournier, in particular, have expatiated upon this point, the former having described some beautifully typical examples of nervous disease occurring within the first year or two of syphilis. In one of his earlier communications, Fournier described a very peculiar form of anesthesia or analgesia, occurring coincidentally with the roseola. That instrument of diagnostic precision, the ophthalmoscope, has demonstrated beyond peradventure of doubt, the occasional occurrence of syphilitic retinitis within or shortly after the first year of the disease.

Some of Hutchinson's cases, are by no means indubitably syphilitic; others, however, are so marked as to be beyond controversy. Apropos of the clinical reports of this confessedly great authority, almost

any conservative diagnostician will, I think, agree with me in the assertion that he displays a tendency to take a great deal for granted. Some of the cases of nervous syphilis which he reports are substantiated by the authoritative weight of an eminent opinion, rather by clinical data. Laying such cases aside, however, enough clearly cut cases remain to demonstrate the accuracy of his conclusions upon the general question of the early occurrence of nervous syphilis.

It has been the fortune of the author of the present paper to meet with a number of cases of varying types of nervous phenomena occurring in the early months of syphilis. Some of the manifestations observed are quite common and would deserve no attention were it not for the fact that their neuropathic origin is not generally understood. I will not attempt to present cases of this kind, inasmuch as the phenomena presented are a matter of common and daily observation. These simpler and more common phenomena constitute a part of the so-called syphilitic fever, and embrace slight neuralgias in different situations, varying degrees of cephalalgia, extreme mental depression, so-called rheumatic pains in different parts of the body. I will also present as neuropathic in character, several other lesions which at first sight would seem far removed from nerve disorder.

The illustrative cases presented do not embrace all of those observed, nor have they been taken at random, but have been selected because of the clearness of their history and clinical evidences of syphilis and their distinctness of type.

*Case 1.—Obstinate and Severe Cephalalgia Occurring Coincidentally with the Syphilitic Roseola.* The patient, a woman about 22 years of age, was brought to me by her lover, who was under my treatment for secondary syphilis, his chancre, which was typically Hunterian, being still present. The history of this woman was one of the most classical that it has ever been my fortune to follow; the case was also a most lamentable one in its results, as I afterwards treated her little daughter for syphilis imparted by the mother in some unknown manner, no chancre being discoverable. In the course of the sixth week after her chancre was discovered, the woman presented herself with a well marked roseola complaining at the same time of the most severe headache. Iritis developed within three months, the headache becoming still more severe. To make matters worse, mercury was badly tolerated. Free inunction having been resorted to, the symptoms were finally brought under control, with the exception of the headache, which persisted with diminishing severity for at least a month after the other symptoms had disappeared. The headache in this case was diurnal, as well as nocturnal with, however, somewhat typical exacerbations. There was at no time such tenderness of the cranial bones as is likely to exist in cases of bone involvement. A source of embarrassment in this case was the necessity for the prolonged administration of morphia, other sedatives having no apparent effect. There was in this case, no previous history of nerve disorder. Pronounced mental depression from worry over her condition and fear of detection, was the only determining cause of the cephalalgia as far as I was able to judge. As might be imagined, the free use of mercurials rather enhanced this condition.

I will again allude to the element of mental disquiet in this case in my analysis of cases.

*Case 2.—Severe and Protracted Cephalalgia occurring in the Fourth Month of Syphilis.*—This case was that of a woman 30 years of age, who gave a very clear history of syphilis. At the time of my first examination alopecia, small mucous patches, faucial engorgement, adenopathy, and a fading roseola were still visible. Spasmodic efforts at mercurial treatment had been made, the remission having been the fault of the patient and not of her physician—a most capable man. Headache came on about two weeks before I saw the case, but had become severe only within a few days. In spite of

active treatment the cephalalgia persisted until I was entirely out of patience with my anti-syphilitic therapeutics. There was a history of previous mild attacks of headache, and an obscure history of rheumatism. I grasped at the latter straw, and although the headache was typically nocturnal, salicylate of soda was given, without result, save that of increasing the patient's anemia. Opiates now became the main feature of the treatment. It so happened that I was experimenting just then with the salicylate of iron. This was one of the few remedies that had not been tried, and I therefore prescribed it, with the gratifying result of effecting a complete cure within a few weeks.

Of the two cases of cephalalgia above outlined, I have been able to follow the subsequent history of but one. Case 1 is at present under observation, and after eight years remains apparently well.

*Case 3.—Severe Intercostal Neuralgia with Symptoms Simulating Pleuro-Pneumonia, occurring coincidentally with the Roseola.* A man, 35 years of age, who was under my treatment for an initial sore, developed in the fourth week a well marked chill followed by fever, attended by cough, decidedly rusty sputa and bilateral râles, painful respiration, dyspnea, and the most severe intercostal neuralgia I have ever observed. The symptoms were verified by two gentlemen who were serving as my assistants. The temperature was only 100 degrees F. and the patient appeared by no means as ill as his symptoms seemed to warrant. I confess, however, that the possible diagnosis of an impending syphilitic eruption which I made, was a very long shot. I must acknowledge moreover, that I ensconced myself behind the possibility of a complicating pneumonia. I prescribed a warm bath and a hypodermic of morphia and on the following morning found the patient perfectly comfortable but covered with a pronounced and well generalized roseola.

The subsequent history was that of the usual tractable case of syphilis.

*Case 4.—Severe Lumbo-Abdominal Neuralgia as the Initial Symptoms of Secondary Syphilis.* A man 40 years of age, consulted me regarding what were apparently soft chancres. These sores healed kindly, but I gave the patient fair warning of the possibility of a mixed infection. After about two weeks following the healing of the non-infecting local difficulty, the patient consulted me regarding a transformation of the cicatrix into a typical initial lesion of syphilis. The new difficulty proved resistant to treatment, and my patient went the way of all disgruntled patients and changed surgeons. The new attendant took pains to tell him I was mistaken and his anxiety was greatly relieved thereby. Several weeks later, however, the patient developed what his doctor styled lumbago; the new symptoms proving refractory, the patient again changed doctors and sent for me. I found him suffering from a most agonizing lumbo-abdominal neuralgia with nocturnal exacerbations. On removing his clothing I found a well marked and extensive syphilitic roseola. This was attended by a temperature of 101 degrees. Under active mercurial treatment this case progressed quite satisfactorily with the exception of the neuralgic manifestations, which lasted nearly a month. Dry cupping and counter irritation were necessary in addition to internal remedies.

This patient stated that he was slightly rheumatic, and on inquiry related a strain which had affected his back some years before his syphilis was contracted. He had never had lumbago and asserted that his back had given him very little annoyance since the old injury.

*Case 5.—Hemianesthesia occurring during the early part of the Second Year of Syphilis.* The patient was a man 35 years of age with an extremely neurotic heredity. He has been a hard worker in his commercial life and at the same time was a high liver and quite intemperate at times. He had been comparatively well, however, until he contracted syphilis about fourteen months before I first saw him. His treatment had consisted of several more or less spasmodic mercurial and iodid courses at the Hot Springs. His symptoms while classical had at no time been prominent, mucous patches and moderate but typical alopecia being the most prominent symptoms. Ptyalism had several times been induced, a fact which should be duly considered in connection with the subsequent neurotic disturbances. At the time I first saw the case no special symptoms were present. The patient was hypochondriacal and neurasthenic, but presented no

pronounced evidence of nervous disease. The treatment prescribed was of a simple tonic character. Here, I think, was an error, and yet I believe that my reasoning was sound enough, as I suspected over-enthusiastic dosing in the previous course of the case. I will say in passing, that I often ignore the syphilis and prescribe for the patient, generally with the best results. Improvement in the patient's general condition was quite rapid. About a month after beginning treatment, however, he fell from grace and made a night of it, wine and women being equally prominent factors in his escapade. The second morning thereafter, I was sent for and found a badly scared and penitent patient with pronounced right hemianesthesia. There was slight impairment of muscular power and marked diminution of the reflexes. The patient stated that his trouble had evidently come on during sleep, as he had noticed nothing abnormal until he awoke in the morning. He said he could walk when he awoke, but that the numbness in his hand and arm was quite distressing, these members feeling as though they belonged to some one else.

The late Dr. Jewell saw this case in counsel and verified the diagnosis of syphilitic disease affecting the region of the internal capsule, without expressing any definite idea of the character of the pathologic process, of which more anon.

Complete recovery ensued under large doses of the iodids associated with liberal inunctions of mercury. This treatment was followed by two years of tonic specific treatment in conjunction with the double chlorid of gold and sodium. The patient is to-day married, has healthy children and is enjoying the best of health.

*Case 6.—Severe Generalized Neurolgia and Spinal Pain Associated with the Roseola—Paraplegia in the same Patient within Eighteen Months.* A man 55 years of age was referred to me by my friend, Dr. Thackery, with what was apparently a soft chancre. This proved refractory in healing but finally cicatrized without induration up to the time when the patient passed from under my observation. Some six weeks after the healing of the sore, the patient again consulted me for what had been termed a lumbago. A few days after leaving me he had developed a severe attack of la grippe from which he was slowly recovering when the so-called lumbago came on. Experience had made me suspicious of lumbago following genital sores, hence I immediately directed the patient to strip. As I anticipated, a pronounced roseola was present. The pain in the back extended until the entire spine was involved, radiating into the abdominal region, thighs and arms; so severe was the pain that the patient was unable to move and could not rest comfortably in any position. Sleep was for a time an unknown quantity. The reflexes were exaggerated and there was no paresis. My friend, Prof. H. N. Moyer, saw the case with me and concurred in the diagnosis of syphilitic involvement of the cord, but I believe that he, like myself, was unable to precisely define the condition. Spinal hyperemia was as definite as anything in my own mind. I fancy that Dr. Moyer rather leaned to the opposite view, but I am by no means positive on this point. Neither of us felt justified in pronouncing the case one of spinal meningitis—a rather plausible diagnosis.

The predisposing influence of grippe received its due meed of consideration. The case proved very stubborn, and the most radical anti-syphilitic measures associated with counter irritation, electricity and massage were for a time almost ineffectual. Inunction to the verge of pyralism finally caused the case to yield, but recovery was very slow. A very important point for consideration in this case was the fact which I afterward discovered, that the woman from whom the patient contracted the disease was with him almost constantly during his six weeks' confinement in bed. This association was by no means platonic, as both parties duly appreciated the fact that they had been quite efficiently vaccinated.

Eighteen months after his apparent recovery, the patient reappeared with paraplegia, treatment having been neglected during the interim. I gave the

patient some suggestions as to treatment, but declined to again take the case. He has apparently recovered, judging by his gait as he walks about the streets. The development of paraplegia within a few months after the original spinal pain is worthy of note.

*Case 7.—Facial Hemiatrophy Associated with Unilateral Deafness Developing in the Early Part of the Second Year of Syphilis.* A man of 30 years presented himself with syphilitic nodes upon the tibiae and a single small tubercle upon the forehead. Syphilis had developed two years previously. About nine months before I first saw him, the patient developed what appeared to be a severe facial neuralgia. This lasted some weeks and as it was subsiding the patient noticed that the cheek upon the affected side was becoming somewhat hollow. The wasting continued for several months but had evidently stopped when he consulted me for the other symptoms. At this time the left side of the face presented a very peculiar appearance, all of the muscles being more or less affected by the atrophic process. The patient stated that for a time he was compelled to masticate entirely upon the right side, but this trouble had disappeared. Thorough treatment with mercury and the chlorid of gold and sodium apparently cured this patient's syphilis, but the facial hemiatrophy remained unchanged. At about the time the facial neuralgia developed, deafness of the corresponding ear was noticed. This increased until the loss of hearing was complete. Like the facial difficulty, the deafness remained unchanged by the treatment.

A very similar case came under my observation several years ago in which, however, the facial trouble did not develop for several years after the primary sore and was unattended by deafness.

Professor Moyer saw this case with me. As in the preceding case, treatment was of no avail.

*Case 8.—Right Hemiplegia in the Third Month of Syphilis.* This case is one of the most interesting of the series. I was called to see a young man of 20 years of age whose friends were evenly divided upon the question of paralysis and acute alcoholism. As the young man was attacked quite suddenly while taking a few social drinks, and was unable to articulate on his arrival home, the variance of opinion was by no means surprising.

On examination I found almost complete right hemiplegia with associated aphasia. According to the statements of his friends, the patient had always been in perfect health. He drank some, but had not been previously known to indulge to excess.

On directing the patient to open his mouth and protrude his tongue—a feat which he found difficult of accomplishment—I detected several mucous patches on the tongue and lips. There was marked mental sluggishness. On stripping the patient I found a well-marked maculo-papular syphilide, comprising a fading roseola and recently erupted papules. Examination of the genitals revealed a typical initial sore with enormous induration, which had been present about twelve weeks. Adenopathy, both general and local was well marked.

This patient recovered completely under inunctions followed by the internal administration of mixed treatment and the protidid in alternation. At present, four years later, he remains well.

*Case 9. Left Hemiplegia Developing Eight Months after the Initial Lesion.*—A young man 20 years of age, was referred to me for partial hemiplegia one week after its onset. On inquiry I found that he had been treated for syphilis in a spasmodic fashion for about eight months. The history was a typical one, mucous patches being still present. No other signs of syphilis save general adenopathy were present.

Recovery in this case was slow but satisfactory. There has been no relapse up to date—three years and a half since I first saw the case.

*Case 10.—Left Hemiplegia Ten Months after the Initial Lesion.* A man 40 years of age consulted me two months after the onset of left hemiplegia. The paralysis had at first been complete, but sufficient improvement had occurred to enable him to get about with the aid of a cane. A clear history of syphilis was obtained, the chancre having appeared about one year before the patient came under my observation.

Treatment had not been systematic. Sterno-clavicular periostitis on the right side and a characteristic thickening of the tibial periosteum were noted.

No other symptoms of syphilis were present. Under vigorous treatment the paralysis improved somewhat, but not to a satisfactory extent. The other symptoms were rapidly relieved. At the present time, nearly five years since he first came under my care, the patient is free from symptoms of syphilis, but is still hemiplegic, the upper extremity being especially disabled.

*Case 11.—Facial Paralysis Developing at About the end of the First Year of Syphilis.* A medical man whom I had previously treated for syphilis, consulted me regarding left facial paralysis, which he believed to be due to syphilis. I confess that there were no definite data for such an opinion, but in view of the history and most rapid improvement after anti-syphilitic treatment was begun, the diagnosis of syphilitic paralysis seemed a fair one despite the possibility of other and more common causes. The patient has been under observation only a few months, but seems quite well at the present time.

*Case 12.—Symptoms Simulating Tabes in the Third Month of Syphilis. True Tabes Developing in the Same Case Six Years Later.* It is by no means frequently that we are enabled to secure as definite data on the relation of syphilis to tabes as in this case. Even in this case moreover there are so many sources of fallacy that the syphilitic etiology of the final ataxic manifestations is by no means proved beyond question. Personally, I am inclined to the view that the late cord disease was of syphilitic origin. Respecting the preliminary attack of spinal trouble, there can be little doubt as to its syphilitic character. The patient was a man of 30 years of age, who had been intemperate and sexually excessive, but quite healthy until he contracted a chancre. This ran a typical course and was followed in the sixth week by a pronounced roseola and a severe type of so-called syphilitic fever, necessitating confinement to bed. Within a few days he complained of rheumatoid pains in his limbs, to which I am free to say, I attributed very little attention at the time. At the end of a week, he attempted to get up and found considerable difficulty in walking. On examination I found the gait of a distinctly ataxic character. There was some loss of sensation and almost complete abolition of the knee reflex. The pupils were normal. The condition did not progress and proved of short duration, a month of vigorous treatment bringing about recovery. For some months, however, the patient complained of a trifling unsteadiness of gait when he had been exposed to overwork or worry. This finally passed away and for some years he remained well.

Six years and a half after the original chancre, the patient again presented himself with symptoms of incipient tabes dating back about six months. The symptoms slowly progressed until quite typical tabes had developed although vigorous treatment had been persevered in. The patient finally passed from under my observation but I afterward heard that he died some three years later as a result of his tabes.

I have met with numerous other cases illustrative of the early nerve disorders of syphilis, but they were either of trifling importance or the data were insufficient to warrant my presenting them to as scientific a body as this Academy.

In several cases I especially regret the lack of data. One such, which I will briefly mention, was that of a young man of 33 years of age, who developed hemiplegia in the second year of syphilis. Following the paralysis which was never perfectly cured, epileptiform convulsions came on. Treatment was of little avail and the patient eventually became insane. Certain property complications made this a *cas celebre* thus enabling me to follow the case after a fashion, long after it passed from my care.

It has been my aim to avoid cases in which the evidence was chiefly hearsay; this may enhance the value of the clinical report. It is perhaps to be regretted that my cases have not been minutely stud-

ied by the neurologic expert, but it will at once be recognized that the neurologist is most likely to meet with the later and more obstinate types of syphilitic nerve disease. A report based upon observations made from the standpoint of the syphilographer, may be of especial value to the general practitioner in the recognition and study of the early nerve phenomena of syphilis.

#### GENERAL CONSIDERATIONS.

The various forms of nerve and brain disease of syphilis, have received attention chiefly as phenomena of late syphilis, and even in the late cases it has been considered sufficient to classify them as nervous lesions, without any attempt at a critical study of the varying conditions underlying them. The terms, diffuse and circumscribed gummy infiltration, have covered a multitude of pathologic conditions of widely varying types. There is to be sure, more uniformity in the pathogenesis of late nerve disease than in the forms, yet in a general way, what I have to say of the precocious forms, will apply in a certain degree to the more systematic later types. There is often in the later forms a very important plus factor in the etiology due to excessive drugging and the syphilitic cachexia. This factor may exist in early cases, but it is exceptional. The prognosis in all forms of nerve syphilis is fairly good, if we except the debatable cases of tabes and general paresis. With early treatment the prognosis is much more favorable than is usually believed even in the late types.

It is worthy of note that the more typical the lesion in late syphilis, the better the prognosis; thus, a definite gummatous deposit may always be expected to yield to judicious treatment. Symptoms which do not yield, are due to lesions which may be termed post-syphilitic in the true sense of the term, or to nutritional disturbances produced, not by the action of syphilitic poison *in loco*, but by the pressure and irritation of products which have usually long since lost their infectious properties. I believe that all tertiary changes are essentially post-syphilitic and certainly can not regard tabes and parietic dementia in any other light, where we have reason to accept them as syphilitic in origin.

The prognosis as regards recurrence is excellent, in well treated late cases of gummatous nerve disease. This is apparently not so true of the early cases. It may be that the necessity for vigorous treatment is not so well appreciated in the earlier periods, but be that as it may, the occurrence of neuropathic disturbances in early syphilis, is likely to be a premonition of future and more serious nerve trouble.

In the writer's opinion, a clear understanding of the principles of pathogenesis underlying the early nervous phenomena of syphilis can only be obtained by regarding the disease as microbial. Independently of the question of the known or unknown character of the germ, analogic reasoning alone should convince the intelligent observer of the logic of this position.

Having accepted this premise, another point is to be considered, viz., the *modus operandi* of the germ. In a general way it may be stated that the germ of syphilis follows a very regular and systematic evolution or life history. As with all pathogenic microbes therefore, we must take into consideration the soil,

the action of the germ *per se* and the action of certain toxins which it produces: 1, by its own excretory functions; 2, by the morbid changes which it excites in the tissues in which it operates.

The action of the germ may be said to be in brief, the excitation of morbid impulses and new properties in certain anatomic tissue elements. These new properties are: 1, a tendency to rapid proliferation; 2, a tendency to fatty degeneration; 3, infectiousness. In time, as the life history of the germ is completed, the property of infectiousness is lost, but the other evil properties remain as long as the least trace of the syphilitic impress exists. The effect of the toxins may still remain but no new ones are formed, save by the cell changes themselves,—metabolic toxins. The tissues know the germ toxins no longer, save perhaps, by their effects. The action of the early toxins may lay the foundation for cell changes which occur long after the germ has fulfilled its mission and disappeared.

The relation of such debatable diseases as tabes and parietic dementia to early intoxication of the brain and cord is yet to be shown, but I feel justified in asserting that such early nerve intoxication may have much to do with these late phenomena. What Hutchinson terms "vulnerability," may thus be rationally explained.

I desire in passing, to state that most physicians regard syphilis in the light of a tissue destroyer, the syphilitic poison being supposed to roam about like the traditional lion, seeking innocent cells and fibers to consume. This is a serious error, and has been responsible for much wild pathology and still wilder therapeutics. Syphilis is a builder of tissue—such as it is,—and destroys, not by corrosion but largely by pressure innutrition. Perhaps some of the severe lupoid, necrotic and phagedenic lesions of tertiary syphilis may be quoted in contradiction, but it would be easy to show their fallacy. As a matter of fact, the disease is only apparently destructive and even its apparent destructiveness is generally manifested after the germ has probably disappeared. With reference to prognosis, there is this to be said, viz., if the syphilized cells constituting syphilitic neoplasia—whether situated in the nervous system or elsewhere—be removed before pressure innutrition and absorption of the tissue elements have occurred, perfect recovery ensues. The more delicate the structure, the more quickly must the removal be accomplished. The practitioner must beware of delay in those obscure cases of sudden deafness, certain cases of disseminate or patchy choroiditis and neuro-retinitis occurring in syphilitics. These affections when neglected in the slightest degree, and often *ab-initio* in *neuro-retinitis*, rank with tabes and general paresis, with respect to their curability.

The practitioner should remember that his remedies may effectually remove syphilis, but may fail to remove the ruins produced by it. Let us examine a scar left by subcutaneous resolution and absorption of a syphilide and then imagine a similar scarring, if you please, of nerve tissue and we can readily understand some obscure points in syphilitic neuropathology and therapeutics. Apropos of this proposition, my position regarding the administration of mercury and iodine as a crucial diagnostic test in some forms of nerve syphilis may be readily surmised. The failure of mercury and the iodids in tabes and parietic dementia, has often been used as

the chief argument of those who deny the specific origin of these diseases. As well say that a long standing case of paraplegia or hemiplegia can not possibly be of specific origin, because forsooth, mercury and iodine will not cure them. Another point: Mercury and iodine may remove the adventitious deposit very quickly, yet fail to impress the new connective tissue which has been thrown out as a consequence of the irritation induced by the syphilitic neoplasia. To the neurologists present there may be nothing novel in this view, yet how few practitioners understand it.

As is readily apparent from what has already been said, I am inclined to place toxins in a very prominent position in the etiology of early syphilitic nerve disease. I also believe in their more remote relation to some of the later types of nerve phenomena. It now remains to consider how the toxins act. As I have observed what I assume to be their effects, I believe that syphilitic toxins act in several ways, viz.:

- |  |  |
|--|--|
| A. By direct intoxication of nerve tissue.   | <ol style="list-style-type: none"> <li>1. Central.</li> <li>2. Ganglionic.</li> <li>3. Peripheral.</li> </ol>  |
| B. By the induction of vasomotor changes via the sympathetic ganglia or the so-called monarchical vasomotor center in the medulla. | <ol style="list-style-type: none"> <li>1. Of the vessels of the central nerve system.</li> <li>2. Of peripheral vessels.</li> <li>3. Of visceral vessels.</li> </ol> |
| C. Direct intoxication and irritation of vascular tissue producing in the nervous system.  | <ol style="list-style-type: none"> <li>1. Active hyperemia.</li> <li>2. Passive congestions.</li> <li>3. Inflammations of lower type.</li> </ol>                     |

The question at once suggests itself; if toxins are present in syphilis and they are so variously and multitudinously pathogenic why do not all syphilitics present such results in greater or less number and severity? To the practical clinicians present, such a query would never suggest itself, but the practitioner who is impressed with the typically specific character and routine effects of syphilis on the average might well be expected to be a doubting Thomas. And let me add at this juncture, that the plus factors in syphilis are too little appreciated even by the expert. The man who sees nothing peculiar in the determination of a mucous ulcer by the irritation of a jagged tooth or the use of tobacco, is at once at sea when confronted with a syphilitic nervous disorder. The relation of cause and effect is, it is true, not so easily determined in the latter, but it is none the less definite. Throughout the course of syphilis we find lesions which are determined by very simple and common factors. Thus mucous irritation long continued determines mucous plaques, ulcers, papillary hypertrophies, fissures, tubercles and condylomata. Gouty and rheumatic irritations of muscle, tendons, ligaments, and synovial membranes determine so-called syphilitic and mercurial rheumatism of such structures. Gout and rheumatism predispose to iritis, neuralgias, and infiltration of arteries. Just so surely do such sources of irritation as alcoholism, sexual excess, the gouty and rheumatic diathesis, mental over exertion or worry, determine nervous disease of a type corresponding to the seat of irritation. This applies not only to the toxin neuroses, but to phenomena due to structural changes, *i.e.*, to syphilitic new growth. The element of heredity is of importance, but as we well know, a neuropathic tendency may exist without it.

## RETRO-DISPLACEMENTS OF THE UTERUS WITH SOME MODES OF TREATMENT.

BY JOHN MADDEN, M.D.

MILWAUKEE, WIS.

The different opinions which have been and still are held regarding the pathologic importance of the retro-positions of the uterus, together with the many different mechanical and surgical measures employed for their relief, form an interesting and profitable study. The subject is not a new one; and it would seem that a sufficient amount of evidence is already at hand to warrant definite opinions and establish well defined lines of remedial procedure. This, however, is not the case; for one who reads the literature of the subject from the time of Simpson to the present day is liable to be a good deal confused both as to the importance of the condition itself and the value of the different remedies for its relief.

Dr. Simpson's articles on retro-position were published between 1843 and 1848. They were the first extensive observations upon the subject which had yet been published. The prominence of the writer brought out many articles on the subject and his extreme views as to the importance of the displacement had many adherents. Thus we find Ashwell in 1844 making the following observation: "Retroversion is an alarming, but a rare displacement and when fully established the altered position of the uterus is most striking. The fundus is turned downward and backward into the hollow of the sacrum, while the os and cervix are carried upward and forward, impinging on or lying above the symphysis pubis. It is the opposite of anter-version and demands more prompt attention; for although at first, neither the structure nor the function of the organ are affected, if it be overlooked or neglected it will not be long ere extreme irritation and danger ensue." (Ashwell, Ed. 1845, p. 418.) Quoting further from Ashwell (p. 420): "Retroversion is not at the moment of its occurrence, except it happen very suddenly, indicated by any marked change in the patient's state of feeling; she generally remains ignorant of the accident until an attempt is made to relieve the bladder. Failing in this she becomes alarmed and uses straining efforts but is unable to accomplish the act. The distension and the inability continue to increase—and in twenty-four hours if the catheter is not used the suffering will be extreme—but the bladder is not the only organ whose functions are interfered with; the rectum is so pressed upon by the fundus of the uterus that constipation and sometimes almost entire suppression of stools ensue." Other symptoms given by the same author are nausea and vomiting, painful fullness in the pelvis, dragging in the loins, and expulsive pains like labor; also stomacic and abdominal pain, fever with quick pulse, hot skin and great restlessness. (*Ibid*).

Views similar to the above were expressed by Rigby, Protheroe Smith, Henesley and other contemporaries of Professor Simpson. These opinions were antagonized, however, by Drs. Bell and Oldham, but their greatest opponent was Dr. James Henry Bennett who, in 1849, criticized the views of Dr. Simpson's followers in the following language: "There has been a great tendency, of late years, to exaggerate the importance of this displacement. The essays of Dr. Simpson himself, although highly practical and interesting, are not free, in my opinion, from this

reproach (Bennett 'On The Uterus,' Ed. 1850, p. 202). I am the more disposed to insist upon the opinions which I entertain upon this subject, as several writers in their attempts to follow Dr. Simpson's researches have published such singularly erroneous statements respecting retro-version of the uterus and its symptoms, that I feel called upon to enter my protest against doctrines calculated to mislead the profession. Thus it is repeatedly asserted that it frequently, if not generally gives rise to all the local, functional and general symptoms and reactions which I have described as characterizing inflammatory affections of the uterus, to engorgement of the uterine neck, to chronic inflammation of the ovaries. ('Sterility and C.,' *ibid* p. 203). These assertions are stated to be founded upon clinical fact; but I firmly believe that they are, to a great extent, deduced from facts misunderstood or misinterpreted." (*Ibid*).

Notwithstanding the protests of Bennett and a few others, the views of Simpson seem to have been generally adopted in England. Previous to Dr. Simpson's publications too, there already existed in Germany and France, quite an extensive literature on the subject of retroversions; and views of their importance as pathologic factors held by the German and French gynecologists did not differ materially from those expressed by the Edinburgh professor. Among those of the German school who wrote of these displacements were Schweighauser, of Strasburg; Bruninghausen, of Wurtzburg; Schmitt, of Vienna; Schneider, of Baldy; and Kirchner, of Poeneck; and of the French the writings of Madam Boivin and Dr. Duges are the most conspicuous. Colombat, the painstaking and conscientious French gynecologist, published his work on the "Diseases of Females" in 1844 (translated by Meigs, Second Ed., 1850). In the preparation of this work, he states in the preface that he has examined the works of over one thousand writers on gynecologic subjects; and as this was more a consensus of opinion rather than a particular dogma of the author, the article on retro-positions of the uterus is reliable, in that it gives what was probably, the approved teaching at that time. Of the symptoms of retro-version this author writes as follows (Meigs' "Colombat," p. 160-161): "Supposing the womb to be non-gravid, and the cavity of the pelvis of ordinary dimensions, if the displacement takes place gradually, the patient begins to feel an inconvenient sense of pressure within the pelvis; then the groins, the loins, and thighs are affected little by little with dragging pains, which become more and more annoying. Soon after this the signs of inflammation of the womb become manifest, and the suffering more acute; the catamenia become disordered, either increasing or diminishing in quantity; a leucorrhœa, which in some instances is bloody, flows during the intervals between the menses; the digestion is deranged; the appetite is lost; the woman grows thin and her strength diminishes. At length a fever sets in which in some cases, is of a high grade and continued type; but in others slight, and characterized only by heat of the skin, and by agitated evenings and nights.

"To the above symptoms, there is always added a sense of pressure at the bladder or rectum, giving rise to frequent desire to urinate or go to stool. During the flow of urine the jet is soon checked or suddenly arrested, and as the displacement always increases in proportion to the efforts made to expel

the urine and feces, the symptoms are always greatly augmented by those attempts." It is needless to point out that in the light of modern pathology, this formidable train of symptoms could not be produced by a mere retro-displacement of the uterus. Here we have an accurate portrayal of infectious invasion of the genital canal, beginning with a vaginitis and ending with profound pelvic inflammation. A striking example of Dr. Bennett's charge that the symptoms are misrepresented or misunderstood. This subject will, however, be discussed further on in this article.

In America, the extreme views of the importance of retropositions were adopted with little reservation. Meigs, writing in 1850, expresses himself thus: "In my opinion a majority of the cases called womb complaint, met with in this country, are cases of retroverted uterus. An ample experience teaches me that such instances are far more numerous than mere prolapsus. Indeed, a simple prolapsus not gone to the extent of procidentia, does not necessarily give the patient a great deal of distress. A woman soon becomes accustomed to a moderate degree of descent of the organ, and does not feel, or even suspect its existence." He further remarks that the accident is very common in girls who lead a sedentary life. In this class of cases, failure to empty the bladder at proper intervals produces stretching of the round ligaments until they become incapable of acting as uterine supports; and, also that the disease "ought to occur as frequently in the sedentary girl as in the wife and mother." (Meigs' "Colombat," p. 160). Sims and Hodge held similar opinions, and the latter will long be remembered for his extreme views regarding the value of the pessary which still have their influence with gynecologists. Dr. Thomas in 1880 ("Diseases of Women," fifth Ed., pp. 436 and 438) gives the usual long list of symptoms produced by retro-displacements of the uterus. Among the consequences of posterior displacements, he mentions dysmenorrhea, endometritis, sterility, aveolar, hyperplasia, and pelvic peritonitis. "Furthermore," says Dr. Thomas, "the body sometimes descends to the upper extremity of the vagina and instances are recorded by Rokitsansky and Schott in which it penetrated the walls of the vagina and rectum, and forced itself into these canals. This is a very rare exception, but it is worthy of mention as showing how great is the pressure which a retroflexed uterus may exert. "As rare complications may be recorded hematometra and hydrometra from imprisonment of fluids by obliteration of the canal by flexion at the os internum."

In Dr. Emmett's article on uterine versions ("Principles and Practice of Gynecology," Third Ed.) an elaborate system of tables is given; but a study of them brings little conviction beyond the fact that inflammatory changes are almost always found in connection with retro-versions.

More recent writers, as a rule, hold practically the same opinions as those already cited. Dr. Geo. S. Harrison, of New York, ("American System of Gynecology," Vol. II, p. 1116) says that "the symptoms of chronic retroversio-flexio are so multiform they embrace the entire gamut of morbid sensations;" and that besides the ills directly referable to the uterus and neighboring organs of which a very long catalogue is given, indeed, "the most varied alienations of the psychical sphere, the strangest forms of anesthesia and hyperesthesia of particular portions

of the body, the most persistent forms of neuralgia, and, finally spasm and paresis involving different groups of muscles, may be dependent entirely upon retroversio-flexio and can be partially or completely relieved only by a restoration of the uterus to its normal position." This author says much more in the same strain, but it is not necessary to quote further from his article to show the importance which he gives to retro-displacements as pathologic factors. Pozzi dismisses the subject in a few lines, quoting the views of others without committing himself (Vol. I, p. 438). Skene in his treatise on the diseases of women (p. 308) mentions the common symptoms referable to the pelvic organs, making the reservation, however, that the suffering caused by retroversion varies greatly in different patients and that one of his patients who had retro-version many years, not only suffered no discomfort, but was one of the most active women he had ever known. Prof. August Martin, of Berlin, ("*Frauen Krankheiten*," p. 90) who mentions the usual symptoms of backache, pressure and dragging down, and vesical and rectal tenesmus found in connection with retro-positions, makes the following remark: "These appearances which are looked upon as quite particularly characteristic of retroflexions, the reactions upon the nerve plexes on the anterior wall of the sacrum and dependent inability to stand and walk belong more frequently, not to the retroflexion as such, but to a perimetritis which exists at the same time, and in these cases generally originates in the same puerperium as the deviation of the uterus, but not caused by it alone." ("*Diejenigen Erscheinungen, welche als gans besonders den retroflexion Eigenthümlich angesehen werden, die Rückwirkung auf die Nervenengeflechte an der Vordern Wand des Kreuzbeins und dadurch bedingtes Unvermögen zu stehen und gehen, gehören viel häufiger nicht zu Retroflexion als solche, sondern zu Einer Perimetritis, die gleichzeitig besteht und in diesen Fällen gewöhnlich aus demselben Wochenbett stammt wie die Deviation des Uterus von ihr allein aber nicht verursacht werden*").

I have taken the trouble to examine all such authorities as I have access to and quoted freely from the same in order to show what has been and what now is the generally accepted opinion as to the pathologic importance of retro-deviations of the uterus as such. A consultation of a great number would probably not change the result, as the opinions quoted are those of representative men. From the evidence here presented, then, we are to believe that retro-version and retro-flexion may be productive of profound anatomic changes, inflammatory in their character and that they may give rise to symptoms "so multiform that they embrace the entire gamut of morbid sensations."

That a retro-version of a uterus otherwise normal and where the other pelvic organs are in a normal condition of health, can produce even a small amount of discomfort, is difficult to believe. The specific reasons given for the suffering caused by the displacement are pressure upon the rectum, producing rectal tenesmus, constipation and other associated ills, and obstruction to the circulation in the uterine body gives rise to uterine congestion, enlargement, metritis and endometritis, also, logically of salpingitis, followed by all the symptoms which these disorders generally produce. In retro-flexions we are to add a greater amount of obstructions, to the

circulation, by reason of the sharp bend in the uterine neck and also obstructive dysmenorrhea resulting from the same deformity. To convince you of the importance which has been given the pressure of the uterus alone, your attention is called to the cases cited by Dr. Thomas, in which the uterus is said to have penetrated the wall of the rectum and vagina, the pressure being so great as to completely obstruct the circulation in these parts. To impress this lesson upon us, Dr. Thomas remarks that "it is a rare occurrence, but it is worthy of remark as showing how great is the pressure which a retroflexed uterus may exert." (*loc. cit.*) The possibility of such a disaster from retroflexion would probably not find any believers at the present time, but the influence of such teaching is still with us.

The unimpregnated healthy uterus weighs from one to two ounces. Its supports are so arranged as to admit of very free vertical and antero-posterior movement. Its blood supply is abundant and the vessels are tortuous, admitting a free amount of stretching without encroachment upon their caliber. In perhaps a majority of cases the uterus rests upon the bladder when that organ is empty. When the bladder is moderately distended the uterus assumes an upright position and when extreme distension of

the uterus will certainly have a greater degree of antero-posterior mobility. It is impossible, under such circumstances that a retroverted uterus could have any pathologic importance, either by reason of its normal weight or that its circulation would be interfered with.

In the case of retro-flexions, excepting where they are congenital, they are probably always preceded by inflammation, usually cervical and corporeal endometritis with elongation and softening of the supravaginal portion of the cervix until it becomes incapable of supporting the enlarged uterine body. Nor is it quite clear how much of the dysmenorrhea met with in retro-flexion is due to the flexion, and how much of the inflammation to the cervical and corporeal endometritis. If the flexion is extreme, so that the axis of the cervix meets that of the body at an acute angle, the mechanical obstruction from this cause alone may, no doubt, be productive of a great deal of suffering. Such extreme cases of retro-flexion are,

Fig. 1.—Long round ligament and broad vesico-uterine peritoneum, allowing free antero-posterior movement of uterus; bladder empty. S, symphysis pubis; B, bladder; U, uterus. (Diagrammatic.)

the bladder occurs, the uterus may be slightly retroverted.<sup>1</sup> The round ligaments are regarded as the principal agents concerned in holding the uterus in its anterior, "normal," position; but they are frequently poorly developed or altogether absent. (Martin's "*Frauen Krankheiten*," p. 78). Another important factor concerned in holding the uterus in its anterior position is the extent of the uterine attachment to the bladder, as indicated by the depth of the vesico-uterine cul-de-sac. I have seen this nowhere discussed; but it is well known that the peritoneum in some cases dips deeply down between the uterus and the bladder, closely investing the former organ to or beyond the internal os before it is reflected upon the latter, while in other cases the cul-de-sac is very shallow, both organs being practically covered by the same fold. The importance of this broad stretch of peritoneum must be considerable, probably as great as that of the round ligaments themselves. When, therefore, the round ligaments are absent or only slightly developed, and when at the same time, the vesico-uterine cul-de-sac is deep,

<sup>1</sup> This is not true in all cases. Dr. George McClellan, of Philadelphia, found by experiment upon the cadaver that "If the bladder is gradually distended, while the bowel is empty, the fundus is raised until the organ assumes a decided ante-flexion." (*Regional Anatomy*, Vol. II, p. 113).

Fig. 2.—Different degrees of attachment between uterus and bladder; 1, 2, 3, different depths of vesico-uterine fold. Bladder moderately distended. (Diagrammatic.)

however, rare. More often the axis of the uterine canal, at the junction of the cervix and the fundus, describes the arc of a circle with a comparatively long radius, the retro-flexion thus, in itself, not offering any considerable obstruction to the passage of menstrual fluid. This is not the case, however, when the cervical canal is already completely occupied by a redundant mucous membrane, the product of a long continued inflammation. It is not necessary to point out here that an endometritis with the uterus in its normal position may be productive of just as much and just as severe dysmenorrhea as the same inflammation produces when that organ is retro-flexed or retroverted. In retro-positions of the uterus, too, especially in retro-flexions, much stress has been laid upon the passive uterine congestion brought about by obstruction of the circulation. Williams, some time ago called particular attention

to the fact that each segment of the uterus is supplied from a different source, so that flexions could not be productive of obstruction. The fundus uteri receives its blood supply from the ovarian artery, the cervix from the uterine artery. Both vessels, with their accompanying veins, lie between the folds of the broad ligaments, beneath the Fallopian tubes. A mere bending backward of the uterus could not interfere with their functions. Let, however, a parametritis take place, an inflammation extending from the tubes to the tissue between the folds of the broad ligaments, and the encroachment upon those vessels with the accompany uterine congestion is easily understood.

What I firmly believe and what I wish to teach is, therefore, that retro-deviation of the uterus is not in itself a pathologic condition; that it is not productive of inflammation; but it is almost exclusively the result of inflammatory process; that the accompanying symptoms are those of the same inflammation when the uterus is not displaced; and that unaccompanied by inflammation, in a normal pelvis, it rarely produces any painful sensation. Exception is to be made in the rare cases of congenital retro-flexion, of a high degree, in which obstructive dys-

distinctive symptoms. When accompanied by any symptoms at all they are those of inflammation of endometritis, metritis, salpingitis and parametritis. I wish here particularly to mention a condition which is common in retro-displacements of the uterus as well as in inflammatory troubles in which no deviation is present, and which is, I believe, often erroneously attributed to the displacement itself, because relief follows a replacing of the organ in its normal position. I refer to the sensitive point which is found on one or both sides of the uterus, in the region of the Fallopian tube, and within an inch of its entrance into the uterus. There can not be much doubt that this sensitiveness is due to a salpingitis which may exist either alone or in connection with an endometritis. It is located in that part of the tube which suffers a free amount of bending motion during the vertical movements of the uterus; and any remedy which will take the weight of the uterus

Fig. 4.—Relation of urethra and bladder to uterus when the uterus is drawn down. (Diagrammatic.)

menorrhoea may exist. It is here to be remarked that the evidence of congenital retro-flexion rests upon debatable ground. Martin mentions one case reported by Ruge, but the age of the subject is not given. Schultze and some others seem to conclude that a retro-flexion existing at the time of puberty is to be regarded as congenital. That this conclusion is valid is very doubtful. There is no reason for doubting that hypertrophic changes may take place in the infantile uterus as a result of infectious inflammation of the genital canal, producing cervical elongation and flexion; and that both the inflammation and the flexion remain unrecognized until the age of puberty is reached. Vaginitis and endometritis gonorrhoeal in their origin, are not extremely rare in young children. I have seen a most violent vaginitis, cystitis, and cervical endometritis in a child 10 years of age, whose father I was then treating for a long standing gonorrhoea. I have seen a similar, but less severe, condition in a child 5 years old. In this latter case the disease was of long standing, and the father confessed to having had a gonorrhoea nearly two years before.

Retro-deviations of the uterus are productive of no

off the tubes and at the same time limit or abolish its vertical movements will be attended by relief, whether the uterine body is put in its anterior position or not. I have often seen such relief follow the mere filling of the vaginal vault with cotton, without any attempt made to remedy the retro-displacement. Where adhesions to Douglass' cul-de-sac exist, the posterior vaginal vault is sensitive, often exquisitely so; but here the secondary influence of the displacement is too manifest to need discussion.

It is not the purpose of this paper to discuss all the mechanical and surgical measures which have been used for the relief of retro-deviations. The most of them are well known and estimates of their value are as numerous at least, as the men who introduced them. I firmly believe, and this belief is founded upon a considerable amount of experience and observation, that through antiphlogistic and anti-

septic measures, temporary artificial support of the uterus where the tubes are inflamed, removal of diseased parts with the curette and by proper operations about a lacerated and indurated cervix, and the restoration of an injured pelvic floor together with proper attention to the general nutrition, will relieve all the symptoms attending retro-displacements in a great majority of cases without paying any attention to the deviations as such. Exception is here to be made where the inflammation has been extensive and destructive, where the uterus is firmly bound down by adhesions.

In concluding this article, I wish to mention only three operative procedures for the retention of the uterus in the anterior position: They are ventro-fixation, shortening of the round ligaments by drawing them through the external abdominal ring and the vaginal fixation of Mackenrodt. Ventro-fixation will

tent and strength of the adhesions which may be produced by ventro-fixation. This patient had been castrated by Dr. Christian Fenger, of Chicago, for a myoma about as large as an orange, situated in the left lateral wall of the uterus. A retro-uterine abscess developed for which I opened the abdominal cavity about a year afterward. There were two very firm areas of adhesion, probably aggregating one square inch and apparently capable of sustaining a weight many times greater than that of this very much enlarged uterus. But the tendency of adhesions thus produced, as in all other cases is toward absorption, making a just estimate of the final results of the operation impossible. If, however, the antero-position can be retained only long enough to prevent a re-adhesion of the uterus should it become again retroverted, the operation has an important place.

Opinions of the value of the so-called Alexander's

Fig. 5.—First step in Mackenrodt's operation. Uterus drawn down and anterior wall of vagina incised.

probably always be performed in those cases of retroversion in which the opening of the abdominal cavity is a necessity, especially for the purpose of breaking up of posterior adhesions. The value of the operation is not yet established. Martin had performed it forty-three times up to Feb. 1, 1893, thirty-one for posterior adhesions, eight times after the removal of myomata and four times for movable retro-flexions. Since the date here given, he has operated in the same manner a number of times but only for posterior adhesions and after the enucleation of myomata. Of the outcome of the forty-three cases here mentioned Professor Martin remarks: "The final results are not brilliant. After one to four years the adhesions of the uterus to the abdominal wall, were so much stretched that the uterus lay free. Sometimes through continuance of the existing perimetritis, the uterus was again brought to the retroflexed position." Only once have I had the opportunity to see the ex-

Fig. 6.—Mackenrodt's operation. Vaginal mucous membrane dissected off, sub-mucous tissue pushed up and secured, and three silk sutures in situ.

operation are indefinite and variable. Beyond a few opinions given off hand I have been unable to find any statistical information upon the subject. The operation is suitable for cases not attended by adhesions. The German gynecologists have practiced the operation but very little. Martin remarks: "The inconstancy of the round ligaments, which I have taken the trouble to establish through my laparotomies has to the present, prevented my adoption of Alexander's operation." (*Frauen Krankheiten*, p. 98).

In 1892, Mackenrodt, of Berlin, united the body of the uterus to the anterior wall of the vagina for the purpose of correcting retro-deviation of the uterus. The operation has since been performed by other of the German operators, but chiefly by Professor Martin, and as practiced by the latter is briefly as follows: With a combination sound and tenaculum forceps, the uterus is anteverted and drawn downward and

outward, until the os is quite without the vulva. With a scalpel the anterior vaginal wall is then split from a point one-third to one-half an inch beneath the urethral opening down to the portio vaginalis. The mucous membrane is carefully dissected off from the submucous tissue for some distance on either side of the incision, the submucous tissue shoved up and its bleeding vessels stilled by several stitches of continued catgut suture. This maneuver leaves the uterine wall bare for the distance of one or two centimeters above the internal os. The vaginal wall is now united directly to that of the uterus by means of three strong silk sutures, the first of which passes through the uterine wall about three-fourths of an inch above the internal os, the second at the internal os, and the third about the middle of the uterine neck. Super-

Fig. 7.—Mackenrodt's operation. Sectional view. V, anterior vaginal wall bent upon itself and secured to uterus. Upper part of vagina distended.

ficial catgut sutures close the spaces between the silk sutures. The silk sutures are allowed to remain *in situ* three months. There is no doubt a possibility of injuring the bladder in performing this operation. The injury may be either direct or through subsequent inflammation of the tissue between the uterus and the bladder. I saw in Landau's Clinic, in Berlin, one such case. There was extreme sensitiveness and other evidences of vesical inflammation. The patient had been operated upon by Dr. Vogel several months before.

The operation is new and therefore its value is unknown. Martin has great hopes of its efficiency and says he has had no complications following it. In the first thirty of his cases pregnancy afterwards

twice supervened and ran a normal course. Mackenrodt mentions one normal pregnancy in his cases. It is quite probable that this operation, like all other new operations, will be illy done and overdone. As a result we shall have much conflicting testimony as to its value.

## INFLAMMATION AND MICROBES.

A LECTURE

BY JOHN D. KALES, M.D.

PROFESSOR OF BACTERIOLOGY IN NORTHWESTERN UNIVERSITY  
MEDICAL SCHOOL, CHICAGO.

A complex but interesting series of phenomena are known to take place when certain living vegetable cells invade an animal tissue and compete with its living units for nutrition. The life and well being of invading bacteria usually means death to the neighboring tissue cells. This issue is resisted most vigorously by those cell elements immediately concerned in protecting the organism. In the more simple forms of life these influences are less complex and are confined to so-called immediate effects, while in the human organism we have not only the immediate but also the remote influences of active efforts at resistance. It is evident that the more complex the organism the more multiple and intricate will be these manifestations. A complex and highly differentiated organism has a temperature regulating mechanism which is easily deranged. It has numerous organs whose secretions and functions may be altered, a highly developed nervous system which responds quickly and often violently to unusual impressions. Then taking the human organism as a type of the most complex, we will note not only the immediate or local effects of an inflammation, but also the remote or general effects. These latter may be even more striking, comprising as they do, a series of reflex phenomena like convulsions, fever, changes in the secretions both qualitatively and quantitatively from the skin, kidneys, salivary glands, etc.

Of late, investigations regarding inflammation have been made comparatively. Metschnikoff's studies of what we might call the evolution of inflammation, have been the most notable contributions ever made to the subject. They demonstrate the potency of studying a subject comparatively. Such study has shown that the lower forms of animal life exhibit the inflammatory phenomena, and what is most interesting to the student they express it in its lowest and simplest terms. As we advance to the vertebrates and rise to the mammalia, one accessory after another is added, until the phenomena as manifested in the human species is seen. By thus studying the evolution of a complex process, we are enabled to give to its various phases their respective values. Values that may be founded upon duration, persistence or fundamental characteristics. Phagocytosis is the most persistent and fundamental phenomenon seen in the comparative study of inflammation.

To define inflammation is perhaps a useless proceeding, unless we can make the definition a basis or text for its analysis. Briefly, we might present it in the following words as: A reaction which living tissues exhibit to *irritation* or *injury*. According to this view the more obscure portion of the subject turns upon the significance of the word *reaction*. The expression, *irritation* or *injury*, conveys a clearer im-

pression to the mind, and bacteria become linked with the subject at this point. The reaction process belongs to living cells and may be divided into a *defensive* and *constructive* stage. The latter might not be called inflammatory in a strict sense of the word. However, the end and aim of the defensive process is to arrive finally at the constructive. In a given wound there may be much or little to defend but the leucocytes are poured out notwithstanding; if not needed for defense they proceed immediately to construction. Defense and construction are supplementary in a process which aims ultimately at restoration. In both steps the same elements, leucocytes and phagocytes play their parts.

So far as defense is concerned, phagocytosis is the most active and striking phenomenon. It is observed in the lowest and slightly differentiated forms of life, as well as in the highest. Comparative study shows that phagocytosis is less active in man than in the lower animals. A high degree of tissue differentiation evidently makes phagocytes less numerous or renders them less effective. This is perhaps one of the sacrifices the human and other highly differentiated species have to make for the advantages of possessing highly specialized tissues.

The next step in the defensive process differs from phagocytosis, inasmuch as it is only seen and studied in the more highly organized forms of animal life. It is in fact a concerted activity, a combination of forces whereby millions of phagocytes and leucocytes do through organization what a single one would do in simple phagocytosis. Instead of one by one englobing bacteria, they by concerted process surround the lot. Thus we get the so-called *circumscribing* action or union of forces with one intent. By it the contest is made to take place within boundaries. This circumscription is in fact a measure of last resort, simple phagocytosis having failed. The end to be attained here is the formation of an abscess. The inflammatory products and irritant materials are hemmed in by the so-called *pyogenic* membrane or wall extemporized for the purpose of limitation. The very natural result of this confinement is the production of those classical symptoms of inflammation, pain, heat, redness, swelling, and loss of function. These symptoms appear more or less prominently according to the results of the defensive process. The contents of an abscess consist of serum, leucocytes, phagocytes, bacteria and chemic toxins with possibly some fibrin and tissue *débris*. Clinically this material is known as *pus*. In the formation of the typical abscess, the aim is one of limitation. An abscess is in a measure destructive, but the damage is confined, and thus the sacrifice of a part is made often for the benefit of the whole organism. The circumscribing action is less necessary on surfaces; it does at times occur and is then marked by a barrier of deep induration.

The defensive process has been seen to consist in a phagocytosis and a circumscribing action, but the same call which summoned the leucocytes to the defensive, leaves them upon the site of injury for the purpose of reconstruction. Defensive and constructive activity seldom go hand in hand; they follow one another, but the way must always be cleared before repair can begin. Construction takes place also with the help of the fixed connective tissue cells and it occurs promptly, providing the energy of the tissue cells has not been entirely exhausted in the

defensive struggle. Construction implies organization or regeneration. It has been stated that specialization or the higher evolution of the tissues of an organism was accompanied by a diminution of phagocytic activity, so the same higher development entails a feebleness in the regenerative or reconstructive function.

We have therefore to consider the human organism as having purchased its higher development at some considerable cost, it being in consequence provided with less active phagocytes for defense and less active leucocytes for construction. In the lower animal kingdom the regenerative function is so active that not only are injured organs successfully repaired, but lost limbs and processes are reconstructed. A lobster having lost his claw can grow a new one. The tadpole may regenerate a lost tail, etc.

In man, mesoblastic or connective tissue almost monopolizes the regenerative function. It is the one tissue that has suffered the least differentiation. Phagocytes and leucocytes are derived from it, and are very largely the agents through which it works. In man a wound or loss of substance of the liver or brain is replaced by fibrous or mesoblastic tissue; the liver or brain cells are too much specialized to be capable of self repair. Observation on all the other tissues of the human body shows a striking feebleness in this regenerative capacity.

Having defined inflammation as a reaction which arose from an irritation or injury, we have now to investigate this irritation. Primarily we can conceive of irritation or injury only as arising from mechanical, chemical or thermal causes. Considering chemical causes only, these may operate directly or indirectly. When *directly*, it can be proved that inflammation may arise through, for example the application or injection into living tissues of some chemic irritant, germ free. This process is chiefly one of experimental interest. The mode of introducing a chemic toxin *indirectly* into the tissues through the agency of bacteria has the widest clinical significance. The direct mode is often misleading, for the direct use of any chemic irritant creates in living tissue a *locus minoris resistentiæ* and may thus ultimately induce bacterial invasion. The direct method should, however, have nothing to do with bacteria, though it would be a purely chemic matter whether we injected aseptically into living tissues croton oil, turpentine or phlogosine, an alkaloidal product of certain pyogenic organisms. If these substances are used we get substantially the same result as in microbic inflammation, though without microbes we miss their peptonizing action which yields the typical fluid pus, while that called forth by chemic irritants is more or less coagulated and semi-solid. It has been called *puruloid* by some writers.

Clinically, bacteria acting as agents for the generation of toxic and irritant material, are by far the most frequent causes for inflammation. Their products are the acting or exciting causes and these are usually alkaloidal or belong to that class known as albumoses or toxalbumens. Hence they fulfill the idea that the irritant must be a chemic one. The mechanical influences of bacteria were at first given considerable prominence, but later and more careful investigation, has shown this to be too inconsiderable to notice. Even in so severe a disease as septicemia, mechanical effects account for nothing.

And again the idea that bacteria simply deprive the tissue cells of their accustomed oxygen and food has been shown to be of altogether minor importance. The action of certain bacteria for harm is an aggressive and strictly positive one.

In certain forms of chronic inflammation, as for example, the interstitial inflammation of solid organs like the kidneys, liver, spinal cord, etc., there exists an overgrowth of the connective tissue framework. There may at first be hypertrophy of the whole organ as is often the case in the early stage of chronic interstitial hepatitis. This is soon followed by an atrophy and degeneration of the functional cells, which advancing more rapidly than the formative process in the framework leave the organ finally much contracted. Contracted, moreover, because of the property of the new-formed connective tissue to shrink after the manner noticed in cicatrices. Such conditions as these, if they are rightly called inflammatory, and it would seem best to call them so, are brought about usually by some chemic irritant whose influence is exerted upon the tissues during a long period of time. Such chemic substances usually act directly upon the living cells. They may be the products of some recent bacterial invasion like diphtheria or more remotely syphilis. Again, they may have nothing to do with microbes, and be the products of the living tissue itself, *e. g.*, uric acid in the lithemic or bile in the cholemic conditions. Finally, it is seen that substances derived from without are equally capable of producing interstitial change, *e. g.*, the prolonged use of alcohol and the effects of chronic lead poisoning.

The influence of these irritants are in the above instances just enough to provoke connective tissue proliferation, while they damage the more highly specialized or functional cells of an organ.

Once more it is seen that higher organization has its disadvantages, in that it ultimately gives rise to cells whose resistance to detrimental agencies are inversely proportioned to their degree of evolution or specialization. A highly specialized cell does better work than one less evolved, but as a compensation it needs greater protection, for it succumbs very readily to harm and there is left little or no prospect of restoration.

We know of large numbers of pathogenic bacteria but they do not all excite inflammation. Inflammation is in many cases a protest on the part of tissues against the toxins of an invading organism. Unfortunately, perhaps, there are some bacteria and toxins that provoke no tissue protest. It is well known that there are many toxic alkaloids that create no inflammatory reaction; *e. g.*, aconite, strychnin, morphin, atropin, etc. The toxins of hydrophobia and tetanus call forth little or no defensive action on the part of the tissues. Very susceptible animals may offer little or no inflammatory reaction to anthrax; thus in man we have occasionally acute miliary tuberculosis. Both illustrate conditions where there is no local protest or circumscribing action, but as a consequence a quick, general, systemic invasion. The insidious character of an infection without distinct local inflammatory manifestations is often seen in syphilis. The local lesion being occasionally too trifling to notice. Man, for example, is not very easily infected with anthrax, hence we expect a vigorous local reaction, and this is usually the case in malignant pustule.

Infection may take place with or without resistance, but inflammation never occurs unless resistance is offered. As tissues approach death their inflammatory vigor diminishes at an equal rate. In all inflammation, antagonism is necessary. Cell antagonism is most typically exhibited toward living microbes, and less toward toxins and chemic irritants.

## THE CENTRIFUGAL MACHINE IN SPUTUM EXAMINATIONS.

BY WALTER G. HUDSON, M.D.

BACTERIOLOGIST TO NORTHEASTERN DISPENSARY; MEMBER NEW YORK PATHOLOGICAL SOCIETY, HARLEM MEDICAL ASSOCIATION, ETC.

Owing to its precision, the diagnostic aid given by a microscopic examination for tubercle bacilli of the properly stained sputum has made this procedure very popular. The only difficulty lies in the fact that, by the old methods of examination, we may sometimes unconsciously select a portion of the sputum that contains no tubercle bacilli, if the entire specimen contains but few.

To eliminate this source of error, I have of late been using with much satisfaction the method advocated by Biedert, employing in addition the centrifugal machine. Where possible, I secure all the sputum raised in twenty-four hours, and add some potassium hydrate solution; this, with the aid of heat, dissolves any lumps that may be present and after a time the mixture becomes quite thin. It is then diluted with water so as to lower the specific gravity, and introduced into a large centrifugal machine. The latter is then run at a high speed for a half hour, which throws down all solid particles, bacteria included; and the specimen to be examined is then taken, by means of a pipette, from the bottom of the conical part of the tube.

I report the following case to show the usefulness of this method:

About a year ago I saw, with a colleague, a dispensary patient of his, Miss M. F., aged 18, who had been suffering for some time with a cough, with slight watery expectoration. At times she had sweats which were not profuse and did not occur often. Temperature 99; pulse 92; tongue coated white. She was anemic, but not emaciated. Both parents were living. She had originally come for a tonic, because her friends told her she looked pale. Happening into his room at the dispensary one day, my friend casually asked me what I would give, as she had not improved under treatment.

Upon hearing the history, I asked for and received permission to examine her chest. The only abnormal physical signs were on the right side where there were some mucous râles, and near the apex I heard a slight pleuritic friction sound, but it was so slight I did not succeed in convincing my friend it was there. The girl admitted that she sometimes had pain in that region, "muscular rheumatism," she called it. Neither of us could detect any consolidation.

Dr. — was positive that there was nothing tubercular about the case, as he had examined the sputum himself. However, as we were both greatly interested in the subject of tuberculosis, he secured another (morning) sample of sputum, and we examined it together at my laboratory. Out of eight slides examined, we found two tubercle bacilli, both of which were in the second preparation. Dr. — insisted that these might be an accidental contamination from

the air, so to decide the question he obtained all the sputum of twenty-four hours, which I subjected to the above process. Result, the first and only specimen examined contained seven tubercle bacilli in one field, and several fields contained four or five.

Two months later, I subsequently learned, during which she had greatly improved on codliver oil and a highly nitrogenous diet, this patient had a fall, striking her chest against a pail; this started up an acute form of the disease from which she died six weeks later.

While this is only one case, it is still a significant one, as the method of examination cleared up the existing doubt, and led to the adoption of a course of treatment that would probably have been successful had not the girl met with the unfortunate accident which we both felt satisfied caused the disease to assume its virulent form.

Where the bacilli are easily demonstrable by the ordinary means there is no call for this method; but since the above experience I should hesitate to say that a given specimen was not tubercular until it had been applied.

73 West 131st Street, New York.

## POST-NASAL HYPERTROPHY IN ITS RELATION TO HAY FEVER AND OTHER DISEASES.

BY W. H. WEAVER, M.D.  
CHICAGO.

The ganglionic system presides over the functions of secretion and excretion, nutrition and circulation, as well as involuntary motion. These ganglia, composing the "sympathetic system," also give warning through their intricate network of connecting nerve fibers, of abnormal conditions. The warning may be sent to the same organ in which the irregularity occurs, or it may be sent to a neighboring organ, or to one quite remote. The correlated action of organs and tissues is fairly well worked out. Diseases apparently neurotic in origin have frequently been proven to depend upon some local irritation. It may not be possible in every case of a certain disease to find the local origin, or to remove it when found, but it should at least be looked for before valuable time is wasted in treating symptoms.

Dr. J. N. Mackenzie has described what has been termed "Mackenzie's sensitive area," *i. e.*, the posterior ends of the lower turbinated bodies and the surface of the septum opposite. The sensitive area of the turbinated body is usually hypertrophied and may be called the sensitive hypertrophy. It may be seen in most cases by posterior rhinoscopy, having a granular appearance, pale and large. The shortest branches from Meckel's ganglion supply this area. Stimulation or irritation of this area through these branches and the irritable ganglion may be reflected in any or all of the ways mentioned; for example, to the nose producing congestion and discharge; to the eyes producing itching of the eyes and lacrymation; to the bronchial tubes producing asthma. This tissue becomes very sensitive to sudden changes of body temperature, receiving a portion of the blood driven from the surface, swelling enormously, and absorbing septic germs, which set up a new attack of rhinitis, commonly termed, "catching cold." This granular hypertrophy is also irritated by odors, dust and pollen of ragweed or other plants. The impression

made on the ganglion is reflected through its various branches, producing in turn the symptoms of "rose cold" or hay fever; through the descending palatine branches, causing itching of the roof of the mouth, most often referred to the point where the nerve emerges from the posterior palatine foramen, as well as through the naso-palatine nerve at the anterior palatine foramen behind the incisor teeth; through the internal nasal branches, causing engorgement of the erectile tissue with the profuse discharge of mucus; through the upper posterior branches, the pharyngeal, and a few branches from the vidian nerve to the mouth of the Eustachian tube and pharynx, producing the itching of the ears and throat, tinnitus aurium and pain in the ears; through the branches to the ophthalmic ganglion, producing the intense eye symptoms observed in many cases; through the branches of the fifth nerve, producing different neuralgias in its domain; through the cervical sympathetic ganglion, producing hay asthma and dyspnea. Thus the symptoms of hay fever are shown to be dependent on the distribution of the branches from Meckel's ganglion, and its connections, irritation of which results from this sensitive hypertrophy. In the milder cases of hay fever, the symptoms of asthma and dyspnea may be entirely absent, as the reflex action is not so intense and does not extend to the more remote organs.

Again, some of the most intractable cases of asthma are cured by removal or cauterization of these hypertrophies, removal of polypi or other intra-nasal irregularities which irritate this sensitive area.

It may be said, then, that in cases of tendency to "catching cold," hay fever and asthma, the cause is local in a great many cases, and as a local lesion it should be treated. After the local irritation has been removed and the symptoms still remain, then it will be time to look for the origin elsewhere. According to Dr. W. H. Daley, we are justified in looking upon hay fever as a pure neurosis only when the affection persists after the removal of the local nasal disease.

In the case of hay fever, it is said by many authors that local treatment of hypertrophy or other diseased conditions of the nasal mucous membrane will cure a great many cases. The statement is too general to result in much good to the patient. When every abnormal condition discoverable by anterior rhinoscopy has been corrected, including Sajous' sensitive areas, and hay fever develops as before, then examine posteriorly, remove the granular hypertrophy and the case recovers during the same season. The intensity of the symptoms is hardly any reduced by anterior treatment and the result is that the patient becomes disgusted and believes what others have told him,—that hay fever can not be cured.

Also, a great many of the worst symptoms of catarrh are quickly relieved if its treatment begins posteriorly. The chronic congestion of the turbinates subsides, as well as the profuse discharges. The bodies are then left to their proper sympathetic influences which regulate secretion of fluid and the other functions of the nasal mucous membrane.

It has been shown that when simple hypertrophy is the cause of the nasal obstruction and the bodies are cauterized deeply, their contraction is often so great that inspired air is not properly warmed and moistened, the throat becomes dry, and the larynx is involved, in which case it is a question if the patient is not in a worse condition than before. In catarrhal

conditions not hypertrophic, deep and destructive cauterization is never necessary and does actual harm. All these results are easily avoided by the removal of the source of irritation to the sympathetic ganglion before any further measures are attempted. A great deal of time will be saved to the patient, and satisfactory results obtained, if the treatment is carried on with a proper idea of the sympathetic influences reflected through the sphenomaxillary ganglion. Simple "hypertrophy" or engorgement is not pathologic but reflex. I believe that deep linear cauterization for the purpose of button-holing the membrane to the bone and thus prevent erection of the turbinated tissue is wrong in theory and barbarous in practice.

I have frequently seen patients who have been treated and cauterized freely for a period of two or three years, until they had concluded that there was no benefit to be derived from the treatment of catarrh and that this so-called radical treatment was also a failure, and who assured me that the only pronounced improvement they had ever obtained was from treatment of the posterior ends of the lower turbinated bodies.

This sensitive area of Mackenzie is also a causative factor in the production of migraine in a certain class of cases which I will describe, and possibly in others. It is well known that stimulation or irritation of one spot or nerve, through correlated action, produces vasomotor dilatation of another spot or organ. The theory of the correlated action of the erectile tissues of the body has been pointed out in an article on "Irritation of the Sexual Apparatus as an Etiologic Factor in the Production of Nasal Disease," by John Mackenzie. He shows that in a certain proportion of women with healthy nasal organs, engorgement of the turbinated erectile tissue occurs at each menstrual flow. This physiologic sympathy becomes painful when the congestion of the turbinates is accompanied with migraine. In two cases of this menstrual migraine under my care, cure resulted from the removal of the sensitive hypertrophies, and what was supposed to be entirely beyond the reach of more than palliative treatment was shown to be easily remedied. The philosophy of migraine may be explained by the action of the sensitive hypertrophy on the ganglion, producing pain through the connecting branch to the sensitive fifth cranial nerve. As a source of irritation to the nervous system and to the tissues of the respiratory tract, these sensitive hypertrophies are of the greatest importance and should be recognized and treated.

In the treatment of these hypertrophies, all anterior obstructions should be removed, such as polypoid deflections and hypertrophies, if necessary, in order to gain easy access to the post-nasal regions. It is understood that the parts are to be brought under the influence of cocaine for the double purpose of an anesthesia and widening the view. After an application of chromic acid with a bent probe, the white and flabby body can be moved about and brought easily into view. There will be increased discharge during the healing process, but from two to four weeks after the operations have been completed, the pharynx is entirely free from the troublesome collections of mucus. If there is laryngeal irritation, it also improves for the same reason. There is usually no pain after the acid treatment and no constitutional disturbance, but often there is

immediate improvement. The electric cautery is hardly applicable, except as a cautery snare; for the reason that it can not be handled with sufficient delicacy of touch. No instrument is so little in the way and so easily handled as the silver probe charged with chromic acid. No application of acid or snare can be made unless there is easy access. I prefer the use of the cold snare when the growth is large enough to engage the wire, and if tightened slowly there is no great amount of hemorrhage. When the growth is not so large, or if for any other reason an acid application might seem preferable, a steady nerve and a knowledge of the topography of the parts is necessary to make an accurate cauterization.

*Case 1.*—Mrs. F., aged 35, has suffered from hay fever regularly since 1891; attacks modified or absent while in Mackinaw. Has also had severe asthmatic attacks for past two winters, "constantly catching colds" and very miserable. Examination showed the posterior ends of the lower turbinates to be very large and sensitive. They were removed with the cold snare last July. During the season just passed she had no symptom of hay fever, and up to the present time has had no symptom of asthma or the usual attack of rhinitis. During the year before, the turbinated bodies had been extensively cauterized from before back, but the posterior sensitive hypertrophies had not been touched and the previous season the attack of hay fever was not modified.

*Case 2.*—Mr. S., aged 40, has had hay fever for the past eight years; also suffered from asthma most of the time. At the beginning of the past season came for treatment, having the symptoms of a very severe attack of hay fever. The treatment was begun with chromic acid cauterization of the posterior sensitive hypertrophies, one side at a time. The improvement was immediate on the side first treated, then also on the other side after its treatment. The asthma gradually improved and has since entirely disappeared. There was also a ledge on the left side of the septum which was removed. Anterior hypertrophies were some snared and others cauterized. The recovery from most of the symptoms was immediate after the use of chromic acid.

*Case 3.*—Mrs. P., aged 42, has suffered from terrific migraine for about three years, mostly at menstrual periods, although at times from over-exertion, excitement and other irregularities of habits. Examination, in March, 1894, showed enlarged posterior hypertrophies as well as hypertrophy anteriorly. The posterior hypertrophies were treated first, followed by anterior treatment with the result of entire cure.

I might report more cases of the same sort, but these will suffice to show that Mackenzie's sensitive area and the sympathetic nerve supply of the nose have more to do with the most distressing symptoms of catarrh, hay fever, asthma and migraine than they have hitherto received credit for.

## ANTITOXIN IN DIPHTHERIA—RÉSUMÉ OF SOME REVIEWS.

BY B. BECKER, M.D.

TOLEDO, OHIO.

*Report of 121 Cases of Diphtheria Treated at the City Hospital, Urban, by W. Koerte.*—The first injections of serum were made in January, 1894, and were continued without interruption in all the children with diphtheria until the end of March. In consequence of a want of the serum the specific treatment was suspended until June, when it was recommenced until July 21. Then a second interval came, until the middle of September, from which time a third series of treatment with serum from the factories at Höchst-am-Main followed. The treatment, besides the use of the serum, was merely symptomatic. In all cases the diagnosis was based on bacteriologic examination. Out of the 121 cases treated with the serum, 81 were cured = 66.9 per cent., and 40 died =

33.1 per cent; that means exactly one-third of the patients. All the cases of diphtheria, treated from June, 1890, to Dec. 31, 1893, 1,160 in number—showed a mortality of 45.1 per cent. Between the periods of the antitoxin treatment (at those times when the serum could not be obtained) there was a mortality of 57 out of 106 cases = 53.8 per cent. These results, although not as favorable as those reported by Roux and Ehrlich, are apparently in favor of the value of the new remedy. For the exact estimation of these observations, however, it is necessary to divide all the cases in different classes, according to the severity of the course of the diseases. Koerte distinguishes: 1, *severe cases*, with grave intoxications. (*Prognosis dubia vergens ad malam*); 2, *moderately severe cases*, with grave local disease but without symptoms of grave general infection, (*Prognosis dubia*); 3, *mild cases*. Forty-three severe cases had a recovery of 41.8 per cent., a mortality of 58.2 per cent. Forty-seven moderately severe cases had a recovery of 70.2 per cent., a mortality of 29.8 per cent. Thirty-one mild cases had a recovery of 96.7 per cent., a mortality of 3.3 per cent.

Of special importance is the observation of the effect in children under 2 years of age. Out of fifteen children of this age seven died and eight recovered. Tracheotomy became necessary in forty-two of all the cases treated with serum, with twenty recoveries = 47.6 per cent., and twenty-two losses = 52.4 per cent. The average losses after tracheotomy, performed under the same indications before the use of the antitoxin, were 77.5 per cent. This remedy has therefore reduced this mortality by 25 per cent.

None of the children treated with the serum before tracheal stenosis was present had to undergo tracheotomy. Worthwhile of mentioning are the results of tracheotomy in diphtheritic patients under 2 years of age. Out of 108 children of this age who were operated from June, 1890, to March 31, 1893, only ten = 9.2 per cent. recovered, while out of eight cases who were treated with the serum three = 37.5 per cent. recovered.

Behring and his co-laborers have emphatically declared that a satisfactory result of the antitoxin injections can be expected only during the first few days of the disease. The earlier the treatment is resorted to the better the results. Koerte's figures prove the correctness of this thesis. Out of fourteen severe cases injected during the first three days, eleven recovered and only three died. In twenty-nine cases the serum could not be used before the fourth day; twenty-two of them died, seven recovered. From the moderately severe cases, who were treated early, eighteen recovered and five died, while from those cases of the same category who were not treated before the fourth day, only fourteen recovered and eight died.

Nevertheless, an early treatment does not absolutely cure all the cases. There are cases of diphtheria which produce a severe intoxication of the whole body so quickly that our treatment remains unsuccessful in spite of large doses of the serum. Koerte gives a number of clinical histories of patients, who died in spite of early treatment with large doses of serum after a short time from sepsis, broncho-pneumonia, nephritis, paralysis and heart failure. In a child, 1½ years of age, which was brought to the hospital with an apparently mild diphtheria and injected with serum on the fourth day of the disease, the condition became worse and worse until the pa-

tient died from general infection. Bacteriologic examination, however, developed the presence of streptococci only and no Klebs-Löffler bacilli.

No disagreeable secondary effect could be observed by Koerte during his experiments with the serum. Very conspicuous, however, was the rapid improvement of the general condition following the serum treatment.

Although the reported figures seem to allow the formation of a very favorable opinion in regard to the serum treatment, Koerte seems to be rather indefinite in his conclusions. He makes the remark: "Bacteriologists say that antitoxin, if early used, will almost surely cure the *genuine* diphtheria. They wish those cases excluded which are complicated by the presence of other bacteria or cocci. In regard to this, I must say that we, as practitioners, when we talk about cure and treatment of diphtheria, must keep in view the clinical symptoms and appearance of the disease, and that under this well-known and fully characterized picture also those cases belong which are described as mixed infections. Every physician will declare such a case a severe one of diphtheria. From this point of view it is at this time not probable yet, that antitoxin will cure *all* cases of diphtheria, in a broader sense. Also the assertion that in an early and sufficient use of the serum all cases of genuine diphtheria can be cured is not proved yet. There is the possibility that in various epidemics those cases of *mixed infection* are so frequent that they make a limit for the use of the serum. In spite of the rather favorable results which I have related, a longer continued observation at the bedside only can bring a decision as to the value of the antitoxin."—(*Berliner Klin. Wochenschrift*.)

A discussion of the antitoxin was brought up at the Medical Association of Munich, after the hearing of reports of cases by Bucher, von Ranke, Seitz and Emmerich. Ranke asserts that diphtheria at Munich is usually a severe affection. Out of 1,048 cases treated during the last seven years, 49.2 per cent. had a fatal issue. In 575 cases operative interference, intubation or tracheotomy, became necessary. The operated cases had a mortality of 65.2 per cent. In December, 1893, the first observations were made with the serum. The doses used at that time were too small, and the unsatisfactory results of the first series must be declared by this circumstance. At the *post-mortem* examinations of injected children, a peculiar form of infiltrations of the lungs was observed, which otherwise is unusual in children, consequently a causal connection of these pneumonic lesions and the antitoxin was thought of; later on, Ranke convinced himself of the harmlessness of the serum, and he left the before named suspicion an open question. The number of observations with serum at the children's clinic at Munich is too small to allow definite conclusions. A series of nine children were treated with Aronson's diphtheria antitoxin. Two of them died. In another series of ten cases with only one death, Behring's serum had been used. Although these results are remarkably good in comparison to those usually observed at Munich, we are not allowed to draw definite conclusions from them. It may appear surprising that in those cases which came to *post-mortem* examinations, the local diphtheritic process had not been ended yet after twenty-two and twenty-eight days, in spite of large doses of the serum. Emmerich in his remarks laid

stress upon the observation that in all the fatal cases of diphtheria at Munich, besides the Löffler bacillus also streptococci, staphylococci or the bacillus pyogenes fetid were found. The following resolution was unanimously adopted by the Association:

1. To give a positive opinion about the value of Behring's serum is not possible at this time; especially on account of the differences of diphtheria in regard to appearance and severity of the disease, only a longer and closer observation can have a positive effect. It must be recommended, therefore, not to expect an absolute panacea, which suggestion should be given to the public also.

2. Our experiences with the antitoxin are of such a kind that we consider it worthy of further investigations and trials, especially in clinical and polyclinical institutions, as those places the most fit for such experiments.—(*Munchener Med. Wochenschrift.*)

*Disagreeable After Effects from Antitoxin.*—Dr. Cuyrim, physician-in-chief to a hospital at Frankfurt-am-Main, published in the *Deutsche Med. Wochenschrift* the cases of his two assistants who both had used the antitoxin on themselves for light angina—the one of a diphtheritic, the other of a merely catarrhal nature. In the first case, the disease disappeared quickly, while convalescence was rather slow. Six days after the last injection (two had been made of 10 c.c. each) an itching urticaria-like eruption was observed at the region of the injections. The temperature was raised again to 39.5 Celsus. Swollen and painful glands were found on the neck, under the maxilla, at the elbows and inguinal regions. Headache and general feelings of sickness and discomfort. On the third day, pain in knee and elbow joints, muscular pain and the feelings of severe sickness were observed. Besides the urticaria, small, red non-itching spots were found at various parts of the body. It was not before the eighth day that all these symptoms and fever disappeared. Convalescence slow.

In the second case, the patient had taken only one injection. On the following day the place of injection was painful, the ability of walking was rendered difficult. Three days after the injection, loss of appetite, sleeplessness, weakness and a peculiar sensation in the limbs were observed. Two days later, severe pain of the neck, temperature 39.1 Celsus, disagreeable itching at the place of injection and at other places, swollen glands, sensation of severe sickness. On the sixth day of the disease, paresthesia in both hands was noticed, likewise pain in both arms, which troubled the patient badly. After the disappearance of all other symptoms this pain continued and was still present after fourteen days. Cuyrim positively traces these symptoms to the antitoxin. The injections had been made strictly aseptic.

We find another case of secondary effect from the antitoxin, published by Lublieski in the *Deutsche Med. Wochenschrift*. A child of 8 years with diphtheritic affection of the nose and throat received three injections of Behring's serum No. 1 (600 units). The local disease disappeared quickly and without trouble. Eight days after the first injection, swelling and redness of both foot joints, especially at the dorsum, was observed. On the following night an eruption like measles came out at the legs and arms, pain at knee, elbow and foot joints set in. Temperature 38 Celsus in the evening. The fever was still increased during the next few days, likewise the pain of the joints. The child was apparently rather sick. On the fourth day of the disease, the temperature reached

40.3 Celsus, the eruption appeared also on the swollen face. Slow recovery.

Four other cases of an urticaria-like eruption and pain of joints and muscles after the injection of antitoxin in diphtheria were observed and published by Scholz in the *Deutsche Med. Wochenschrift*. All these after effects were of a light nature, disappearing in three or four days.

*Prophylactic Inoculations with Serum.*—In a meeting of physicians of Alsace, held October 27, Dr. Wick reported that he had made prophylactic inoculations in ten children of different families, in which he was treating cases of diphtheria. Children over 6 years old received 2 c.c., younger ones 1 c.c. of the serum. Out of these children, two were taken sick on the fifth, and one on the sixth day after the injection with very mild diphtheria. Bacteriologic examination proved the presence of the Löffler bacilli.

At Königsberg, sixty-four children in thirty-five families were inoculated by the University Policlinic as a prophylactic measure. In the beginning  $\frac{1}{2}$  and later 1 c.c. was injected. The diagnosis was based on bacteriologic examination in the diseased brothers or sisters. Out of ten children, inoculated with Behring's normal serum, No. 1, four had diphtheria; out of eight inoculated with the six-fold Aronson serum, none; out of eighteen inoculated with the thirty-fold Aronson serum, two, and out of twenty-eight inoculated with the sixty-fold Behring serum, one became diseased. All the cases which were taken sick after preventive injections recovered and had the disease in a mild degree. (*Deutsche Med. Wochenschrift.*)

## ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.

NEW ORLEANS, LA.

(Continued from page 169.)

### CHAPTER IV.

*Case 12.*—Yellow fever. Wm. Thompson; age 23; native of Germany has been in Louisiana eighteen months. Taken sick in the country with intermittent fever; returned to the city after a few days; was seized with a violent chill, followed by continued fever until day of entrance into the hospital. Large muscular man; blacksmith by trade. Entered Charity Hospital October 27. Patient had been in bed twenty-four hours with fever before entering hospital.

#### REMARKS.

October 27.—Was much excited; face flushed; gums red; tongue furred; eyes injected, hemorrhage from gums; some headache; cannot bear the gas light; great thirst; ice in small fragments, milk and brandy diluted with seltzer water.

October 28.—Did not sleep during night; relieved the bladder by the catheter; urine scant and high colored, loaded with albumen; ordered sulpho carb. of sodium 3ij in 6 powders, one powder every three or four hours.

October 29.—Did not sleep during night; restless; skin dry; great pain in region of kidneys; no urine is passed; ice cold injections caused the excretion of a very small quantity of light-colored urine loaded

with albumen. Hemorrhage from the gums profuse, also free epistaxis; patient greatly alarmed and restless.

October 30.—No improvement; takes little milk and seltzer water and brandy; skin is still dry; tongue dry and bleeding.

October 31.—Patient has not slept at all and is in a state of low delirium; passes his urine and feces in bed; lies in an apparently insensible condition, but taking nourishment in small quantities when forced upon him.

November 1.—No change, except for the worse; still in an unconscious state; low muttering delirium; cannot collect any urine; passes the small amounts in bed; severe hemorrhage from stomach and lungs; expectorates blood.

November 2.—No change; in same condition.

November 3.—Loud stertorous breathing; hemorrhage; blood still runs out of his mouth.

November 4.—Continues to grow worse; body emits a horrible stench; expectorates blood; blood oozes from nostrils and gums.

November 5.—Wild delirium, requiring two men to hold him in bed.

November 6.—Continues in state of wild delirium.

November 7.—Sinking rapidly; died 1 a.m., morning of Nov. 8, 1873, with profuse hemorrhage.

*Post-mortem Examination.*—Eight hours after death. Body of a deep golden color; mouth full of black vomit, which trickled down the side of the body; bladder contained not more than 5lj of light-colored urine; stomach was filled with black vomit, and capillaries were congested; kidneys congested and mottled; liver of a nutmeg color and oily when first seen, when washed and exposed to the air sections of the liver presented a true yellow color; had yellow flabby and fatty old adhesion in right lung; blood thin and watery. All organs showed capillary congestion. Gall bladder contained but a small quantity of bile.

*Case 1.*—Yellow fever, complicated with pneumonia. Wm. Thompson, large muscular man, blacksmith by trade; age 22; native of Germany. Entered Charity Hospital, Ward 13, Oct. 27, 1873. Has resided in Louisiana eighteen months. Went out to Bayou Têche to work on plantation; after remaining there two weeks, returned to the city, and after being in New Orleans one week, was taken with a slight chill, followed by fever October 27, the day upon which he entered the hospital. The following is the record of the pulse, respiration and temperature:

## REMARKS.

October 27.—Very much excited; face flushed; eyes injected; gums red; cannot bear gas light; hemorrhage from gums; entered evening of October 27; pain in head and back; hot skin; restless; anemia.

October 28.—Tongue very red at tip and edges; bled from nose at 1 p. m. and 7.30 p. m.; complaints of some pain in forehead, lumbar and epigastric regions and extreme capillary congestion; foul breath and odor.

October 29.—Complaints of intense headache and sleeplessness; epigastrum tender upon pressure and painful; great pain in region of kidneys; suppression of urine.

October 30.—Albumen and casts in urine; jaundice; capillary congestion; did not sleep during night; hemorrhage from gums.

October 31.—Jaundice; capillary congestion; prostration; suppression of urine; ice cold injections cause the passing of some urine loaded with albumen.

November 1.—Intense jaundice.

November 2.—Profuse bleeding at nose; blood oozes from tongue and nose; dullness upon percussion of lower lobes, both lungs; embarrassed respiration.

November 3.—Bloody sputa; blood oozes from gums.

November 4.—Bloody sputa and bleeding gums.

November 5.—Bloody sputa; blood oozes from tongue and gums and nose.

November 6.—Bloody sputa; blood oozes from mouth and nose.

November 7.—Bloody sputa; died at 12 p. m.

## NECROPSY TEN HOURS AFTER DEATH.

Body still warm; limbs, face and trunk full; surface of deep saffron yellow color; intense jaundice; lower dependent portions of head, neck, trunk and extremities mottled with dark purplish ecchymoses. Black vomit running out of corners of mouth. Thorax: Heart firmer and more contracted and of not so decided a yellow color as in uncomplicated yellow fever. Under the microscope, however, the muscular fibers were loaded with granular matter and oil globules. The pericardium contained two fluid ounces of yellow serous fluid. The right auricle contained a golden-colored clot, attached to the auriculo-ventricular valve. The formation of the clot appeared to be due to the supervention of the pneumonic in-

flammation. The lungs were congested; lower lobes of both lungs solidified, in state of gray hepatization and infiltrated with bloody purulent fluid. In the blood from the cavities of the heart, the majority of the colored blood corpuscles were normal in appearance; some were crenated and stellate in shape. No bacteria or vegetable or animal organisms were observed in the blood from the heart. Abdomen: Liver mottled upon surface, yellow and purple and bronze. Gives evidence of pervading malarial disease. The yellow fever deposit of oil globules and yellow granular matter was very evident in many portions of the liver. Under the microscope the liver was loaded with oil globules and granular matter and also contained black pigmentary matter. Gall bladder relaxed and apparently empty, contained about thirty grains of thick deep green, almost black, ropy liquid, which under the microscope was found to consist of desquamated liver cells, granular casts of the biliary tubes, and cells from the walls of the gall bladder, discolored by the coloring matter of the bile. The bile in cases complicated with malarial fever, presents a deep green color. Walls of gall bladder greatly congested and of deep purple color. Spleen enlarged to about twice the size and contained pigment particles. Kidneys congested; when washed, of deep yellow color. The bladder contained small quantity of golden urine, loaded with albumen casts and cells of tubuli uriniferi. Stomach and intestinal canal congested. Mucous membrane of stomach deeply congested.

*Case 2.*—Yellow fever; jaundice; severe pain in heart; slow pulse; death. James H. Campbell; age 48; native of New York; has resided in New Orleans twenty-two years; occupation, carpenter. Seized with pain in head, followed by fever Oct. 17, 1893. Entered Charity Hospital October 21.

## REMARKS.

October 21.—Conjunctiva and skin very yellow; tongue red at tip and edges, coated and deeply furred in center; gums very red; patient emits a highly offensive odor.

October 22.—Jaundice, nausea and vomiting; bowels moist; very offensive smell emitted by patient; respiration rapid and panting; dull and drowsy.

October 23.—Patient complains of intense pain in the region of the heart, expressive of fright; in the evening partial suppression of urine; ice cold water administered by enema.

October 24.—During this and the preceding day the tongue and mouth have been so dry that the tongue is protruded with great difficulty; tongue furred and cracked; very red at tip and edges; intense jaundice; tongue swollen; speaks with great difficulty, dull and lethargic; urine contains albumen, granular casts and detached cells. Ice water injections into rectum has caused free secretion of urine.

October 25.—Tongue swollen, cracked and bleeding; jaundice intense; upper surface of tongue red and furred, under surface purple.

October 26.—There has been a marked rising temperature.

October 27.—Complaints of intense pain in right hypochondriac region; countenance anxious and disturbed; jaundice.

October 28.—Pulse slow, only 56 per minute.

Died Oct. 28, 1873, two or three hours after the last observation. Died with slow pulse, low temperature and rapid respiration. This patient entered in a state of intense jaundice and great prostration. Pulse so slow that it could not be counted.

*Case 3.*—Yellow fever; jaundice; urine contained albumen; rapid pulse; death. A. L. W.; native of Ireland; age 20; sailor; in port one month. Taken sick October 22, and was sent to the Charity Hospital three hours after beginning of illness. October 22, 1874, 8 p.m., pulse 125, respiration 35; temperature of axilla 104.2 degrees. October 23, urine contains albumen and casts; congestion of capillaries; face

very much congested; tongue red at tip and edges, furred in center; gums swollen and very red; great tenderness of epigastrium on pressure; 8 P.M., pulse 118; respiration 30; temperature 102.2 degrees; 8 P.M., pulse 120; respiration 32; temperature 104.1; urine loaded with albumen and casts; very scant. October 24, nausea and vomiting black vomit; can retain nothing on his stomach; 8 A.M., pulse 105; respiration 26; temperature 101.5 degrees; 8 P.M., pulse 102; respiration 25; temperature 102.4 degrees; urine scant, could collect but one fluid ounce; loaded with albumen and casts; black vomit continues. October 25, 8 A.M., pulse 96; respiration 24; temperature 100.2 degrees; 8 P.M., pulse 107; respiration 26; temperature 99.4 degrees; black vomit; urinary suppression; died shortly after last observation, October 26, 4 A.M. This case, which ran a rapid course, terminated with a temperature of the axilla but little elevated above the normal standard. The diminution of the rapidity of the action of the pulse and respiration, also corresponded with the diminution of temperature.

*Case 4.*—Yellow fever; jaundice; formation of bed sores and large abscess on thigh; death at the end of four months from effects of abscess of thigh; the pulse during convalescence was more rapid than in uncomplicated cases of yellow fever, which pass to convalescence and complete recovery, without the supervention of local inflammations. Emanuel Scheise; age 37; native of Germany. Has been residing on Frenchman Street. Entered Charity Hospital, Ward 25, Oct. 29, 1873. On entering the hospital the patient stated that he had been suffering with a high fever for three days. This fever was accompanied with violent pains in supraorbital, lumbar, and epigastric regions, and pains in the eyes and lower extremities. At the time of his entrance into the hospital the patient was jaundiced, had fever, nausea, and hemorrhage from the nose and gums. The capillary circulation was sluggish and the urine scant, albuminous, with casts of the tubuli uriniferi. The patient was treated with the sulpho-carbolate of sodium, 20 grains every four hours; ice water injections to the rectum, brandy and water charged with carbonic acid gas, iced milk, beef tea and ice bags to epigastrium. Although hemorrhage took place from nose and gums and jaundice supervened the patient passed safely through the active stages of yellow fever. When, however, convalescence should have been established, the pulse and temperature continued above the normal standard; the patient complained of great pain in left groin and thigh. The limb became enormously swollen. A large abscess finally formed which was opened on January 7 and discharged over half a gallon of offensive pus. The patient died February 24, after prolonged and intense suffering from the abscess and from several large bed sores, on the hips and over the sacrum. The following is a record of the pulse, respiration and temperature:

## REMARKS.

October 30.—Complains of great weakness; conjunctiva of eyes yellow; surface slightly yellow; tongue very red at tip and edges; gums red and swollen; teeth covered with sordes; breath and odor of body very offensive; bowels constipated; passes urine freely; stomach irritable; tenderness of epigastrium; hemorrhage from gums and nose; thirst; great dryness of mouth and throat.

October 31.—Urine contains albumen and yellow granular casts, and cells from tubuli uriniferi; eyes congested, surface congested and yellow; pain in epigastrium, nausea relieved; conjunctiva of eyes yellow and congested; tongue red at tip and edges, and heavily coated in the center; gums red and swollen; urine high colored.

November 1.—Diarrhea; stools are very offensive and of a light yellow color; jaundice, capillary congestion; eyes congested, red and jaundiced; complains of pain in right ear.

November 2.—Complains of severe pains in groins; urine contains albumen casts and bile.

November 3.—Pulse frequent, full and strong; pains in groins very severe; lymphatics swollen and painful.

November 4.—Pulse frequent and strong; has fever; pain located in left thigh, which is swollen, painful and tender; albumen in urine, but diminished.

November 5.—Pain and swelling in thigh continue.

November 6.—Perspiring freely; pain in thigh very severe, it is necessary to use opium freely; the bowels are kept open and the patient supported with tincture of cinchona.

November 7.—Thigh swollen and hard and very painful; thigh painted with iodine, tincture of bark and sulpho-carb; alcoholic stimulants.

November 8.—Pain and swelling of thigh; applied ointment, compound of tincture of iodine and opium, f. 5ij and sulpho-carb. 3ij.

November 9.—Opium internally; with bitter tonics and alcoholic stimulants applied, together with the local applications to be productive of good.

November 10.—Pain less; improving; albumen in very small amount.

November 11.—Pain less; appears to be improving.

November 12.—Thigh not so painful, but still much swollen; patient sits up with some difficulty.

November 13.—Weak, but with some appetite.

November 14.—Pain and swelling in thigh continues; whole thigh from hip to knee swollen.

November 15.—Pain and swelling in thigh not so intense.

December.—During the remainder of November and during December swelling of leg continues, also hectic fever; temperature rises from 100 to 103 degrees; pulse 90 to 110.

January.—On the 7th of January abscess of thigh opened, discharging a large quantity of fetid matter; pulse report 100-120; temperature 101 to 104 degrees.

February.—During the months of February and January had sores formed upon hips and on sacrum; hectic fever; loose bowels; rapid pulse; great emaciation; fever; temperature from 101-104 degrees. Died worn out by fever and suffering Feb. 24, 1873.

In this case the patient passed safely through a severe attack of yellow fever, and then fell a victim to one of the occasional results of this disease, namely, abscess. The effects of the local inflammation in presenting the marked depression of the pulse are clearly shown in this case. I have recorded many cases illustrating the marked reduction of the beats of the pulse during the stage of so-called calm or depression and of convalescence in yellow fever, and will only adduce the following:

*Case 5.*—Yellow fever; jaundice; black vomit; hemorrhage from bowels; urinary suppression; fatal issue. Jacob Geir, native of Germany; age 39 years. Several years in this country. During the past seven months has been in the South, on a plantation near Baton Rouge. The white laborers, as well as himself were all attacked with fever. About two months before entering Charity Hospital, came to New Orleans, and was at that time suffering with malarial fever, which recurred at intervals up to the time of his admission. Admitted to Charity Hospital, Ward 22, Nov. 22, 1873, in the evening. November 23, 8 A.M., conjunctiva of eyes congested and yellow; skin of face and trunk yellow and congested; tongue red at tip and edges and furred in center. When the fingers are pressed upon the surface white spots remain into which the blood slowly returns and restores the florid congested appearance due to sluggish capillary circulation. Pulse 96; temperature 103.5 degrees. November 24, 8 A.M., pulse 84; temperature 101.2 degrees. Bowels loose during the night. Urine scant; nausea; threw up black vomit at 9:30 A.M. Reaction of black vomit strongly acid; urine albuminous, with granular casts of urinary tubes and desquamated cells from excretory tubes. R. Sulpho-carbolate of sodium 3 iij. Divide into six powders. One powder every six hours. 8 P.M., vomiting of black vomit continues. Since this has begun the temperature has progressively declined. Pulse 82; respiration 30; temperature of axilla 98 degrees. November 25, during the night passed by the bowels black excrements mixed with blood. Only three fluid ounces of urine have passed during the last twenty-four hours. Urine yellow, turbid, loaded with albumen, casts and cells. Casts and cells of deep yellow color. Great capillary congestion; dependent portions of body mottled and of a purplish yellow hue. Hands and feet cold; the depression of temperature extends up to elbows and knees. Pulse can be scarcely felt at wrists. Temperature 98 degrees; pulse 70; respiration 26. 6 P.M., temperature 100 degrees; pulse 60; respiration 24. Black vomit and bloody black discharges from bowels still continues. November 26, 8 A.M., insensible; pulseless; temperature 98 degrees; respiration 20. Died at 11:30 A.M.

*Case 6.*—Yellow fever; black vomit; death. *Post-mortem* examination three hours after death; characteristic lesions of yellow fever. Daniel McMenagale; age 18; native of Ohio; left his native State two years previous to the present attack; resided in Memphis, Granada and Vicksburg; came from the latter place, and has resided in New Orleans two weeks. Has had chills and fever at various times during the

past two months. Entered Charity Hospital Oct. 11, 1873, 6 p. m. I saw this patient for the first time at 8 a. m., October 12. Intellect dull; patient unable to give a connected account of the present attack of fever. Surface of body covered with petechiæ; gums red; tongue red at tip and edges; body of tongue coated with yellow fur. Epigastrium tender on pressure. Conjunctiva of eyes yellow and injected. Tongue cracked and bloody. Blood oozes from the tongue, and also from the gums. During the night the patient vomited freely, and the matters ejected from the stomach contained flakes of dark blood. Only a small quantity of urine, about two fluid ounces were passed, which contained albumen and bile, and casts of the tubuli uriniferi and excretory cells. Injections into the rectum of ice-cold water were ordered, and these appeared to restore to a limited extent the action of the kidneys: The following table embodies the prominent symptoms:

Date.	Pulse.		Resp.		Temp	
	M.	E.	M.	E.	M.	E.
Oct. 12	110	112	22	26	104.6°	105.5°
" 13	110	112	29	34	104.5°	104.7°
" 14	116	130	35	38	103.3°	103.3°

## REMARKS.

October 12.—Body emits a foul odor; surface covered with petechiæ: Intellect dull; tongue soft and cracked; blood oozing from cracks in tongue; tip and edges of tongue red; center coated with yellow fur. Conjunctiva yellow and injected. Capillaries of surface congested, giving a dusky, mottled appearance. Urine scant and contains albumen, bile and casts of tubuli uriniferi, and few cells. Nausea and vomiting; vomited matter streaked with blood specks. Treatment: Ice-water injections; ice-bag over epigastrium. Brandy diluted with water charged with carbonic acid. Feed milk and beef tea.

October 13.—Patient dull and stupid; action of kidneys feeble. Condition of intellect due in part at least to failure of function of kidneys and retention of excrementitious matter. Ice-water injections have increased to a small extent the excretion of urine, but the amount is still far less than normal. Urine contains albumen, bile and casts of tubuli uriniferi. Patient has thrown up black vomit in considerable quantities. Black vomit acid and contains urea. Repeat cold water injections and ice to epigastrium.

October 14.—Patient dull and lethargic in the exercise of the intellect. Talks incoherently; very restless; attempts to get out of bed and speaks of going home. Has passed a small quantity of urine, albuminous and loaded with casts (granular and yellow), and also contains bile. Great capillary congestion of surface; jaundice; spits up black vomit against the wall and over the bed like tobacco juice; the black vomit appears to come up without any effort. Can retain nothing upon his stomach.

Died October 15, 6 a. m.

During the night of October 14 the patient discharged black vomit from his mouth, over his bed and against the side of the wall. The black vomit appears to come up apparently without an effort. Surface of the body of an intense yellow, with great capillary congestion. Only a small quantity of urine was collected from the 12th up to the time of death, although the nurse states that the patient has "passed his water in the bed," after the administration of the ice-water injections. The application of bags of ice to the epigastrium did not arrest the nausea and vomiting. The sluggishness of intellect and delirium increased progressively from October 12.

*Post-mortem* examination, three hours after death: Body of a golden color; lower portion of a purplish, mottled appearance from capillary congestion. Dark brown blood, black vomit, issues from the corners of the mouth. Blood issues from the left ear. Thorax: Lower portions of lungs congested; otherwise normal. Heart: Muscular structures of heart present a yellow appearance, as in fatty degeneration of this organ: Under a magnifying power of 450 diameters, the transverse striæ of the muscular fibers were found to be indistinct, and the fibrillæ were filled with oil globules, and granular albuminoid or fibroid matter; the oil globules were also deposited around the fibrillæ. The albuminous substance of the sarcolem elements of the fibers were evidently in an altered and degenerated state, being resolved into granular matter and fat. Heart still warm, and its fibers filled with dark fluid blood, which coagulated and changed to the arterial hue when removed and placed in glass vessels. Under the microscope, with a magnifying

power of 450 diameters, the vast majority of the colored blood corpuscles presented a normal appearance, while a few presented a crenated and stellate appearance. The blood corpuscles adhered together, forming rolls, as in the blood of inflammation. The blood contained oil globules. The dark pigment particles, as well as the colored corpuscles charged with pigment particles, characteristic of the blood in true malarial paroxysmal fever were entirely absent. After careful microscopic examination, I discovered no living organisms, neither bacteria, fungi, algae, or animalculæ of any description in the blood. Reaction of the blood very slightly acid. Fibers diminished in amount. Clot voluminous and soft. Upon standing, a small amount of golden-colored serum, containing also some colored corpuscles, was pressed out of the coagulum; the fibrin of the clots, however, manifested very feeble contractile powers. Pericardium greatly congested, the smallest vessels being distinctly seen, filled with red blood. This congestion of the pericardium appears to be characteristic of yellow fever. Abdominal cavity: Liver presented a yellowish mottled appearance. The mottled appearance of the liver was due to the congestion of the hepatic capillaries within the central portion of each lobule.

The periphery of each lobule, in the area occupied by the portal system of capillaries, presented the deep yellow color characteristic of the liver in yellow fever. Upon careful inspection of the surface, and of sections of this organ, many portions were found to be without any marked capillary congestion of the hepatic capillaries, and presented a uniform yellow color. Upon a superficial examination of this organ, as it lay in its natural position in the abdominal cavity, the appearance resembled that of the liver of health, the color approaching Spanish brown; when, however, it was carefully examined, within and without, the characteristic change induced by the disease was evident; and when sections were subjected to the gentle action of water, and the excess of blood pressed out of the capillaries the color was uniformly yellow, as in the livers of those who had died at a more advanced stage of the disease.

The depth of color of the liver in this case was due to two causes: 1, to the great congestion of the hepatic (central) capillaries; and 2, to the presence of dark granular masses of hematin, scattered chiefly through the meshes of the portal system of capillaries, and which had evidently been deposited during the preceding attacks of malarial paroxysmal fever.

It is probable that such cases as the one now under consideration have led superficial observers to assert that the liver presents no characteristic lesion in yellow fever. Under the microscope, the liver was observed to be loaded with oil globules. Fatty matter in the form of oil globules of various sizes, was accumulated within and between the cells. The structures of the liver were firm, and the blood also changed to the arterial hue upon exposure to the atmosphere. While, therefore, the microscopic examination revealed the effects of preceding malarial disease, at the same time, it also clearly illustrated the pathologic changes induced by the yellow fever poison. The muscles of the walls of the abdomen and of the chest, when exposed to the atmosphere assumed a brilliant scarlet color, wholly unlike the dark color of the muscles in malarial fever.

Gall bladder entirely empty; contained no bile. Kidneys: Congested and of a yellow color, resembling

the color of the heart and liver. The yellow color of the kidneys was especially evident when sections were washed under a gentle stream of water. Sections of the kidneys, with Valentine's knife, examined under magnifying powers of various degrees, revealed the presence of oil globules, granular albuminoid or fibroid matter, and detached excretory cells within the Malpighian corpuscles and tubuli uriniferi. The blood vessels of both the cortical and medullary portions were congested with blood. Both the cortical and medullary portions presented a yellow granular appearance. Many of the uriniferous tubes presented a yellow opaque appearance, being completely filled with yellow granular matter, oil globules of various sizes and detached epithelium. This yellow opaque matter resembled in all respects that composing the casts of the tubuli uriniferi found in such abundance in severe cases of this disease. In some tubules the epithelial cells could not be discerned, either because they had been detached and removed, or else because they were obscured by the oil and granular matter with which the structures were infiltrated. In portions of the kidneys the oil globules were observed around as well as within the tubuli uriniferi.

**Bladder:** The urinary bladder contained about eight fluid ounces of golden or orange-colored urine. Reaction of urine, acid; specific gravity 1012. Albumen present in considerable amount. Under the microscope, detached cells from the tubuli uriniferi and yellow granular casts were observed in considerable numbers; but as usual there were no crystalline forms of urinary deposits. No living animal or vegetable forms were observed in the urine. Urine contained no grape sugar.

**Alimentary canal:** Stomach and intestines somewhat congested upon the exterior. Mucous membrane of stomach moderately congested in some portions, and in others patches were observed of a deep red color; it was also denuded of epithelium in some parts.

**Black vomit:** The stomach contained about eight fluid ounces of thick, grumous, dark, purplish black, bloody looking black vomit. Under the microscope the black vomit was found to contain some oil globules of the milk administered to the patient, with numerous black masses of hematin, altered blood corpuscles, epithelial cells and patches, and fibroid and granular casts of the mucous membrane of the stomach and broken capillaries.

The black vomit, although taken from the stomach only three hours after death, and while the body of the subject was warm, emitted a foul, putrid odor, as of decomposed blood. Upon careful microscopic examination I discovered no animalculæ or vegetable plants (fungi or algæ) in the black vomit. Reaction of black vomit slightly acid.

The spleen was enlarged and somewhat softer than in health, but much firmer than in recent cases of malarial paroxysmal fever.

(To be continued.)

CENTRAL DISPENSARY AND EMERGENCY HOSPITAL, WASHINGTON, D. C.—At the regular monthly staff meeting held on the 2d inst., the Senate Committee on appropriations has reported favorably on the item of \$15,000 for maintenance of the hospital.

## NEW INSTRUMENTS.

### A MASTOID GUIDE AND SEPARATOR.

BY SETH SCOTT BISHOP, M.D.

PROFESSOR OF OTOTOLOGY IN THE POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL OF CHICAGO.

This instrument is so constructed as to serve two purposes in operations on the external auditory canal and mastoid process. The end of the handle is fashioned into a periosteum separator for the canal, and is useful in Stacke's and other operations that require the separation of the integumentary canal from the bony meatus.

It is used as follows: After the incision is made behind the attachment of the auricle, and the mastoid periosteum is lifted from the bone by the large elevator as far as the border of the bony canal, this small separator is introduced between the posterior osseous wall and its periosteal covering with the convex surface of the instrument against the bone. The end of the handle is then pushed carefully inward with the scraping surface directed firmly against the bone until it reaches the middle ear. The instant it arrives at this cavity can be determined by the fact that resistance to the onward progress of the separator ceases at that point. Now the cutaneous canal and periosteum are lifted as far as necessary by lateral movements of the scraping edges.

In caries of the bone in the tympanic cavity, great care should be exercised to avoid wounding the facial nerve, in case the Fallopiian canal is diseased or partially destroyed. This precaution, however, is just as necessary when knives are used, as is the present custom.

This separator has several advantages over the knives: It preserves the periosteum; it does not cut the cutaneous canal; it does not chip and hack like the knives; it is easier to manage; it is adapted to both large and small canals, and it reduces the number of instruments to be looked for and handled. The scraping edge should not be sharp enough to cut the fingers of the assistant who holds it as a mastoid guide.

Its advantage over the mastoid directors now in use is in the shape of its foot plate, which is tapering from heel to toe. This form admits of its being introduced into the aditus or the antrum through an opening that is too small for the present broad instruments to enter. Its wedge shape facilitates its passage through a narrow opening in the bone, when the latter is softened by caries, where the other guides refuse to enter.

I have found by a series of experiments with this instrument that the facial nerve can be protected from injury by the chisels, gouges and curettes if the guide is held with the foot plate resting in the aditus ad antrum, and the handle so directed across the patient's cheek as to lie in a line with the lower border of his upper teeth or lip. In this position the foot plate lies over the Fallopiian canal, and must be held steadily in this position so that the operator's

instruments will come in contact with the guide before they can penetrate deeply enough to reach the Fallopian canal and facial nerve.

This instrument was made for me by Charles Truax, Greene & Co., of Chicago.

Columbus Memorial Building.

### Proceedings of the First Meeting of the American Academy of Railway Surgeons.

Held at the Grand Pacific Hotel, Chicago, Ill., Nov. 9 and 10, 1894.  
(Continued from page 134.)

FOURTH SESSION, SATURDAY, NOVEMBER 10, 9 A.M.

DR. H. J. MAYNARD in the chair.

DR. A. RHU, Marion, Ohio, was called upon to act as Secretary during the temporary absence of Dr. Webb J. Kelly.

DR. R. S. HARDEN, Surgeon Erie Railway Co., of Waverly, N. Y., read a paper on

#### THE BEST METHODS FOR APPROXIMATELY DETERMINING THE AMOUNT OF DAMAGES SUSTAINED BY A TRAUMATISM, FROM A MONETARY STANDPOINT.

In determining the proximate amount of damages by traumatism from railway accidents, we will invariably find ourselves embarrassed, and as Dr. Fitzgerald, of California, says, "involved in metaphysical distinctions and subtleties difficult of satisfactory application." Each case must be decided with reference to the circumstances peculiar and applicable to it. First, I believe all elements not proximately the cause of such traumatisms, should be eliminated. The railway corporation should not be held responsible for remote results, dependent upon aught else than actual negligence or fault of their own. Certainly, if a person suffer from a traumatism, and at the same time from psychic shock, the latter should be carefully considered or eliminated, and damages considered mainly upon objective indications upon the same lines followed by accident insurance companies. Prospective claim for damages, coupled with the inevitable hypnotic element, render the effort to determine the amount of actual or approximate damages satisfactory to claimant, even upon a basis of pure justice and equity, extremely difficult.

Sympathy for the injured and popular sentiment against wealthy corporations evolves suggestion, and prospective damages excites auto-suggestion, the latter stimulating the imagination and in time, if the case be not settled, aggravating the actual objective conditions, and causing subjective and psychic disturbances realistic to the hypnotic mind of the patient, which are often serious in themselves and sometimes even fatal. These well authenticated conditions exemplify the importance both to the injured and the company of early settlement.

In my own experience as authenticating physician for insurance companies, I have often heard the expression by attending physicians that they found it extremely difficult to cure their patients on account of their expectancy of prospective claims or benefits, hence, delay in settlement of claims against the company is attended with increased and increasing liability on account of the development of neuroses and other conditions resultant, it may be, from suggestion and auto-suggestion or hypnotism purely; but at the same time, to the claimant tangible, and before the courts often considered as proximate sequences of the original traumatism. "A result may be physically secondary and consequential, and yet in legal contemplation be proximate."—(See Col. Report, Vol. IV, page 345.)

In determining approximate amount of damages it should first be ascertained whether the company's act is the proximate cause of the injury. The legal test is—and we must constantly bear that in mind—"Was the injury of such character as might reasonably have been foreseen or expected as the natural result of the act complained of?" "A party is not, in law, chargeable with results which do not naturally and reasonably follow as the consequence of his conduct."—(Sackett's Inst. to Juries, page 274.)

The decision of the Supreme Court of Pennsylvania in the case of Ewing vs. Pitts., Cin., Chi. & St. Louis R. R. Co., has an important bearing upon this point also. While we are not to treat this subject from the standpoint of the claim agent we must bear in mind, as we proceed, the legal

aspects which in all cases may be prospective. We cite the above case reported in *The Railway Age*, Feb. 19, 1892.

The syllabus reads as follows: "Permanent injury to the nervous system resulting from fear caused by a collision on defendant's road, due to defendant's negligence, in consequence of which the cars were thrown against the plaintiff's dwelling house in which she then was, will not support a cause of action; the permanent injury is not the natural result of negligence complained of." Continuing the court says: "It is plain from the plaintiff's statement of her case, that her only injury proceeded from fright, alarm, fear, nervous excitement and distress. There is no allegation that she had received any bodily injury. If mere fright, unaccompanied by bodily injury is a cause of action, the scope of what are known as accident cases would be greatly enlarged. For in every case of collision on a railroad the passengers, although they may have sustained no bodily harm, will have a cause of action against the company for the fright to which they have been subjected."

Thus we find, as a matter of law, damages to be reasonable must be the natural and reasonable result of the company's act or negligence. The liability of the company having been already determined or admitted, we then come to the question of reasonable approximate monetary damages. We must now take into account many circumstances, among them:

Mental distress or anxiety.

Psychic or hypnotic elements.

Loss of time and its actual monetary value.

The approximate amount of permanent injury.

The approximate effects of traumatism upon the expectancy of life.

Constitutional diseases and previous conditions.

Prospective damage by impairment of earning a livelihood.

Deception, means of.

Importance of early settlement as a means of restoration to health, and the duty of the railway surgeon to place the matter before the unfortunate claimant in its true light.

Many other matters might be mentioned, but the scope of this paper forbids.

Among the leading methods of examination, we will first emphasize the importance of avoiding suggestive questions, (the importance of this will be explained fully in other portions of this paper).

Referring to instruments of precision, we will not often find their use necessary; occasionally in the hands of the specialist, the dynamometer, audiometer or aesthesiometer may be found of service, and likewise the electric battery, but the use of the latter is exceedingly unreliable as a test of nervous or muscular excitability, if we are to accept the views of prominent authorities, and it has been thoroughly demonstrated that the preservation of normal faradic excitability in a muscle, does not prove that the muscle is not paralyzed.

1. Probably the first circumstance of importance in our examination and approximate estimate of damages, will be the mental anguish or distress of the claimant, consisting perhaps of grief and sorrow over the loss of a limb, becoming deformed, or suffering impairment of future earning capacity, etc. The courts having decided such mental anguish and grief to be proper elements for damages. (See case *Schmitz vs. St. Louis, I. M. & S. R. Co.*) The court in this case declares: "Mental anguish in a boy 9 years of age, consisting of grief and sorrow over loss of his limb, and becoming a cripple for life, is a proper element for damages in an action by him for injuries sustained by the alleged negligence of a railway company at a highway crossing," also that "prospective damage by the impairment of plaintiff's capacity for earning a livelihood after his majority, is a proper element in an action for personal injuries by a minor 9 years old, although his petition contains no specific allegation in regard thereto, and there is no direct evidence on the subject."

2. We should consider the psychic or hypnotic features of the case, bearing in mind that human nature would not be what it is if expectant pecuniosity did not in some measure hypnotize the claimant. There are many cases on record which we will not, for want of space recall, where slight and unimportant injuries developed various emotional and hysterical symptoms, followed by preferment of claim for damages, and where such psychic neuroses have developed into very serious mental trouble, and resulted in large amounts being awarded the plaintiff by the jury and followed by a complete restoration to health.

Oppenheim, who is probably the highest authority we can quote, says: In his experience and in his view, psychical disturbance and change, amounting almost to insanity, have

a more prominent place in the history of accident cases than is generally accorded them. He speaks of anxiety growing into real pathologic entity. If this be true of the German, then we should certainly find it more frequently among our blended nationality in this country who are, as a rule, of a highly nervous temperament. Charcot says that "traumatic suggestion" often takes the place of "oral suggestion." Sir James Paget declares the fault is rather in weakness of the will than in its perverse strength and that when the patient says: "I can not," it looks like "I will not," but it is "I can not will." He says hosts of cases establish this fact that patients will not or can not make the necessary effort to resume work so long as the settlement of their pecuniary claim is unaffected.

Apropos of this element, and perhaps disproving fraudulent intent, is the statement of Brouardel and Pouchet that they discovered in cases hypnotized into convulsions the convulsive ptomaine, and in one greatly depressed and shocked an anesthetizing ptomaine; probably these ptomaines are the results of psychic shock. Seguin says it has been known for several years that in perfectly healthy persons serious nervous symptoms may be produced by hypnotic or by non-hypnotic suggestion; he also mentions a source of persistence and aggravation of symptoms, strangely overlooked by nearly if not all writers, namely, "sympathetic care." In my own experience this has for years engaged my attention. A long-faced, kind-hearted and sympathetic nurse or attendant I have found as fatal, in some cases, especially those of traumatic neuroses, as the bite of a cobra. How many present ever saw a case of "traumatic neuroses" complicating a severe external traumatism? It rarely does so. A passenger, drunk or asleep, escapes the symptoms of "traumatic neurosis" in great measure, at least it is so admitted by all writers. They are not hypnotized by the horrifying excitement of their environment.

The fact that cases of psychic neuroses are long in recovering, or perhaps do not fully recover, Dr. Seguin claims is an argument that there is organic lesion.

Many cases of supposed malingering are, no doubt, honest types of "hypnotic neuroses." We should take this fact, now so well authenticated, into account, and consider carefully every feature of the case. It is my opinion that cases of glaring fraud are not common, but a very large element of unconscious and unintentional fraud nevertheless exists in these cases of traumatic neuroses or subjects of auto-suggestion. In private practice we are constantly misled by our neurotic patients, where no other element exists to influence deception than one of morbid exaction of sympathy or desire to cause their friends to share in their sufferings. Patients will manifest the greatest surprise if it be suggested that they should resume work. When a man has been prostrated by illness or injury and convalescence has set in he must make some voluntary effort to regain his former activity.

3. *Loss of Time and Its Actual Value.*—This will depend in large measure upon the conditions and circumstances attending each case. We must consider in this connection only damages for actual value of time lost. We shall refer, in a classification of injuries commonly met with, to the approximate value of time lost, etc. The practical question is, What is the actual pecuniary loss? The party suffering from a traumatism may claim that they would not have had such an injury or accident with its attendant risks for a large amount, but we do not take into account solace of that character. The courts have so ruled.

4. *The Approximate Amount or Extent of Permanent Injury.*—In the mind of the traumatized sufferer, this element we will usually find exaggerated. The courts and juries have never imposed upon the surgeon that he should promise recovery, or contract to unite bones which have suffered fracture, and I believe it is also a fact that courts of law do not, as a rule, find against corporations or defendants in litigation cases, damages for aught but such conditions as cause actual pecuniary detriment; hence we must exclude deformities which do not involve loss of function and also eliminate fright neuroses, which, though permanent perhaps in character, are not properly to be considered as the proximate sequence of the company's negligence or fault.

It is at once evident that a deformity or neurosis which involves a permanent impairment of function and resultant loss throughout the balance of the life of the party should be considered, and compensation corresponding to the pecuniary loss in each case advised. Such cases are extremely rare, aside from the injuries attended with loss of limb, ankylosed joints and severe sprains, accompanied with rupture of tendons or ligaments. We should exercise extreme caution in all other cases of alleged permanent injury, as

the expectancy of monetary reward is notoriously a prominent factor as an incentive to fraud. Thousands of well authenticated cases have been reported, and I have myself testified to permanent disability in more than one case and found, to my disgust and chagrin, that the payment of a handsome award for the alleged permanent damages was followed promptly by a rapid recovery. A case in point, reported by my uncle, Dr. Lewis A. Sayre, will illustrate this feature, where a man was treated by him for a fracture of the spine, by suspension and plaster jacket, resulting in perfect recovery two years subsequent to a railway company's paying him a judgment of \$30,000 for permanent disability.

The mention of this case calls to mind the astounding fact lately published that the railways of Europe paid, prior to 1888, for spinal injuries alone, upwards of two million dollars. In the light of the present day, and largely as a result of the brilliant and remarkable efforts of the members of the National Association of Railway Surgeons, the fact is made clear to railway managements that a large share of this money was fraudulently obtained. The mimicries of spinal tenderness are often simulated, and it is now a recognized fact that spinal tenderness, by itself, has but little significance in reference to diseases or injury to the cord. In considering the permanent character of alleged spinal injuries we should learn an important lesson from the observations and experiments of Manley upon seventy-one human beings and twenty-two animals and also the experiments of the late Professor Watson, showing the extreme improbability and rare occurrence of permanent injury to the spinal cord from extrinsic or excentric injuries; also that injury to the spinal cord is exceedingly rare in traumatisms not involving fracture. We should also bear in mind that many cases of functional paraplegia have been observed to recover after settlement of claim.

In a digest of 400 consecutive cases of railway injury by Dr. Howard J. Williams, of Macon, Ga., 4 cases of apparent spinal traumatism occurred, 2 of which proved to be shams, 1 was attended with fracture and 1 with hemorrhage into the cord. Among a much larger number of cases of railway traumatism in my own practice during the past twenty-two years, I have met with but one case of spinal injury and that was attended with fracture, followed at once by paraplegia, and death after several years.

Pope, the eminent surgeon, says, "After tabulating 230 cases of spinal concussion from railway injuries, that the great majority of them were tinged with the coloring of imposition."

Pain in the region of the spine is not, in itself, indicative of anything more serious than muscular or ligamentous strain or "entasis" as it is designated by some French authors, and cystitis often ascribed to paralysis of the neck of the bladder, will often be found to be simply the result of residual urine while in the recumbent position. Numbness and "tingling" may be symptoms of significance, although subjective, but is often due to local or external injury.

5. *The Approximate Effects of Traumatisms upon the Expectancy of Life.*—In determining this element or factor from a monetary standpoint, we must take into account the age and previous conditions of health of the injured party and the degree of shock. It is a well established fact that those past middle life suffering from severe traumatism, attended with serious shock, do not so fully recover therefrom, and it is a matter of common experience and observation that they do not attain to the usual period of longevity in many cases. It will also be well for us to bear in mind the fact that a feeble constitution, or one enfeebled by disease, is more likely to be shattered or permanently injured and life itself or the expectancy of life cut short. These and other like conditions bearing upon the expectancy of life, should be noted and considered in mitigation of amount of monetary award for damages, as the company is not responsible for conditions not naturally and actually the result of their negligence or fault. If the life be cut short by reason of previously existing disease, or as a result of prior injuries in any degree, then we should eliminate to that extent, approximately, the liability of the company and the amount of award.

6. *Constitutional Diseases Having an Important Bearing upon Traumatisms.*—We will find it important to consider carefully the indications pertaining especially to phthisis and syphilis, bearing in mind the very large percentage of the population affected in some degree by these formidable constitutional conditions. We will very often find serious traumatic results complicated by these insidious enemies of the human race, both of which hide behind the mask of secrecy. Sagacity and tact are requisite to ferret out these and all

other conditions, not actual sequences of the company's fault, that exact justice be done to both parties; and while the courts do not usually debar from compensation on account of these taints, we must consider them in order to form a correct estimate of the probabilities of recovery.

Herbert W. Page, M.A., M.C. Cantab., F.R.C. Surgeons of England, in his excellent work on "Railway Injuries," 1892, says: "That while victims of railway collisions are not by any means exempted from liability to suffer from every form of lesion of the spinal cord and its membranous coverings, accumulated experience leaves no longer any doubt that these grave results are most uncommon and that it is the extra-spinal structures which, in ninety-nine out of a hundred cases, bear the brunt of the violence and suffer from it," and "that secondary and remote degeneration of the cord, in cases where there has been no distinctive evidence of injury, is very rare indeed." It would appear from these brief references to the phantom "railway spine," and the views of the highest authorities that we must not consider spinal affections or traumatism even, when attended with syphilitic taints, as permanent conditions entitled to monetary compensation as such.

7. *Prospective Damage, by Impairment for Earning a Livelihood.*—This we referred to in the beginning of our paper, quoting from "A Page of Law," from notes of recent decisions by the courts in *The Railway Surgeon*, of Sept. 11, 1894. We consider this, as referring more particularly to minors. It may be there is no present disability on account of the age of the injured, but in justice and equity we must consider his future, and the probable impairment of earning capacity based upon the nature of the case, his environments, prospects, etc. The subject is covered under the head of permanent injuries, etc.

8. *Deception.*—Not in the language of sentiment, but of sober fact, who can measure the extent to which people will go in this direction, and we are not now speaking of auto-deception but of the wilful malingerer? Herbert Page says: "The means of deception are curiously alike." This, because they learn through the press of symptoms of disease and injuries, or acquire such knowledge by suggestion from friends; but we will only allude briefly to this element; its powerful influence in railway cases is notorious and in this day thoroughly understood.

9. *Importance of Early Settlement.*—We should exercise care in early settlement that no injustice be done the claimant. The company can afford to be liberal with him, and perhaps award him in excess of what even he himself or his friends might consider ample compensation for actual damage sustained. They can afford this in many cases for the reason that, as a rule, they save money by so doing on account of many features already mentioned in this paper, but in my opinion, it becomes our duty not as claim agents, but as honorable members of an honored profession to make plain to the claimant the advantages to him from an early adjustment of his claim, not from a monetary point of view, but with regard to his own physical welfare. What does money amount to, obtained after years of litigation and mental worryment, which, in itself, often completely breaks a man down, compared with his health? He should be shown the physiologic and psychologic facts that are so well authenticated as tending to compass his physical and mental impairment. It is certainly a well recognized fact that early settlement is, in many cases, a curative agent.

#### CLASSIFICATION OF INJURIES.

In attempting a classification of the more important traumatism, those commonly met with in railway practice, and the best methods of obtaining the approximate amount of monetary damages, we must consider the fact, now so well established, that the consequences of railway injuries are more grave than those attending accidents in other branches of industry; this both on account of the nature of the violence producing them, and from the fact that nearly all railway traumatism are septic when they come under the care of the surgeon. Often the shortsightedness of the railway company, in not fully comprehending the economic value of competent and skillful treatment at the hands of surgeons fully abreast of the times, and the failure to adopt a surgical service that would result in the selection of a staff of such skilled and experienced surgeons, results in a large monetary loss to the stockholders of such corporations. I will only allude to two cases, among many thousands of like nature. One, where \$20,000 was obtained as a verdict, in lieu of \$5,000, which would have been the probable limit if the injured man had received proper treatment. The doctor in this case—for he certainly was not a surgeon—applied

elastic constriction upon the proximal portion of the extremities for forty-eight hours, and gangrene supervened with the medico legal results mentioned. The other case I have already mentioned, that reported by Dr. Lewis A. Sayre. Decisions of the courts, holding the company responsible for conditions following—even where clearly the result of such improper treatment—indicate to us that we can not eliminate damages in any degree on that ground.

1. We will consider compound fractures, as they are undoubtedly much more frequent than simple fractures in railway surgery and fraught with vastly more serious results especially, as we have indicated, in the hands of surgeons who do not practice aseptic surgery, and strange as it may sound to you experienced gentlemen, at least 50 per cent. do not. Only a few years since such conditions were expected to suppurate and granulate, and "laudable pus" was an indication of successful treatment, and the monetary damage and loss greatly enhanced thereby, it being generally conceded that a compound fracture would entail double the time in healing and be attended with many times the cost of medical attendance over a case of simple fracture. Any rules or schedules of fees for such injuries made ten years ago, certainly would require revision at this time, as most cases of compound fracture treated under strict aseptic principles are but little if any more formidable, or attended with much greater monetary damage to the claimant than in the case of simple fracture. In a given case of compound or comminuted fracture in which we find the external wound has healed by first intention, differing but little, if at all from the simple fracture, and where no great blemish or deformity remains, or any loss of function is apparent, we will not usually find it incumbent upon us to consider any element other than loss of time and its value, as permanent loss of function is very rarely observed following the conditions described; we should, however, bear in mind the approximate amount of time requisite for repair and restoration to normal degree of useful function, remembering always that muscles are only restored to vigor and normal power after fracture, by voluntary effort and proper exercise. Many a patient has become a hopeless cripple, simply because he "could not will," or did not, at any rate, exercise his will power—as Dr. Seguin puts it. In these cases the courts seldom make any exception, therefore, we must often find it necessary to consider such conditions. Under favorable and proper conditions we will be able to approximately determine the extent of lost time, from the observations of surgeons of large experience, but in individual cases it will vary somewhat.

1. *Fracture of Femur.*—From my own experience and that of others, I should consider in a case of compound fracture of the femur, that the degree of disability was total for at least six months, and partial six months; and at least four months of this time we should consider that total helplessness obtained, requiring an attendant. In this case we should also make an exception to ordinary fractures, compound or otherwise, on account of the inevitable shortening and the fact that but few people suffering this fracture escape some degree of deformity. In estimating the monetary damage this must be considered and aside from this, I believe, as compared with other fractures of extremities in continuity the damage would be four-fold. It is comparatively easy for the claim agent to approximate the amount by methods familiar to him, and followed by the Pension Department, taking the simple fracture of the lower extremity or forearm as a basis or starting point. Fractures of femur—intra-capsular—are so exceedingly rare in railway practice—as aged people to whom they are common, are infrequent travelers—they need scarcely be considered, but on account of the fact that they seldom if ever unite by bone, and that they are attended by serious deformity, the monetary damage exceeds by far that of any other, unless it be fracture of the pelvis.

2. *Simple Fracture of the Femur.*—Excluding cases of non-union—such fractures are exceedingly rare—and the cause of such non-union, usually some dyscrasia, or lack of osseous element, the fault of the patient's own system, we will not usually find the damage much, if any less, than in the case of compound fracture of the femur, provided perfect asepsis has been followed out in the latter. Taking into account, however, the greater expenses attending this fracture—about three times that of simple fracture of the arm or leg—and the greater degree of suffering, tedious convalescence, slow restoration of muscles to their former activity, and from the functional ankylosis of the joints, and the slight deformity resulting from what Prof. Frank Hamilton declares the "inevitable shortening," we must consider them,

and approximately determine the damage, after taking into account the claimant's circumstances, earning capacity, etc. as indicated in previous classifications.

Fractures of the femur near, and involving the knee joint, on account of resulting ankylosis, and perhaps destruction of the joint, are much more serious, and should be classed with compound fracture of the femur not treated aseptically.

3. *Compound and Simple Fractures of the Leg.*—We classify them together, because as before stated, the approximate damage is, or need not be, under asepsis, but little if any greater in the former than the latter. Fractures in this region are undoubtedly oftener attended with non-union and deformity than in the upper extremity; in other respects the conditions and considerations obtaining with respect to damages are about the same; possibly a slight difference as regards the period of convalescence, should be considered. Fractures of the lower extremity, not having so perfect a circulation, process of repair does not so quickly or certainly follow. Cases of non-union or necrosis seriously impair the nervous system, and through the agency of sepsis break down the whole system and render the question of damages a serious one, and such cases if brought into the courts are often attended with judgments for large amounts. This should be borne in mind. If such conditions be attributed by the claimant to fright or shock at time of injury, then we should consider the decisions of the courts bearing thereupon which I have quoted; and for the simple reason that but very few coincide in their views with these decisions, I will enochao upon your time by quoting a recent decision from the *Medico-Legal Journal* of New York, of September, 1894. In *Haile Curator vs. Texas and P. Ry. Co., United States Circuit Court of Appeals, 60 Federal Reports, 557*, it was held that, "when a passenger on a railway train receives no bodily injury in an accident, caused by the excitement, hardships, and suffering resulting therefrom, the company is not liable in damages therefor, since insanity is not a probable or ordinary result of exposure to a railway accident." In the light of this and former decisions quoted, we must not consider fright or psychic shock. Non-union or necrosis would not be the "ordinary result" of such conditions, and surgical experience has fully proved them to have invariably resulted from well-known systemic conditions in the vast majority of cases.

4. *Fracture of the Arm and Forearm.*—In these fractures we will find the same general conditions to be considered as already mentioned in other fractures. We should consider the difference in right or left, as the usefulness of the member is not so important a factor in the left as in the right arm. A person suffering fracture of the former will not be so long disabled as in the latter, consequently the element of lost time and its value, differs materially. Considerations of permanent injury will seldom attach to fractures of the arm or forearm, unless complicated with injury to joints, which will be classified separately.

The slight deformity usually following fracture at the wrist, (Colles fracture) if not attended with loss of function must not be taken into account, as such slight deformity is the "proximate and usual result," under the most approved treatment.

The approximate amount of damages in case of fracture of the arm, is a proper basis of damages for other fractures, as it is seldom attended with permanent results and future impairment of usefulness. The value of time, expenses incident to it, and reasonable compensation for partial loss of function, beyond, say three months, which would be a fair approximate of the total disability, in a case, compound or simple, not complicated with loss of tissue or comminution of bone. Under contusion and lacerated wounds, mention will be made of such cases.

Fracture of ribs, not attended with perforation of lung, we will not often be called upon to consider. Fracture of pelvis, when not fatal, is a formidable condition of as grave a character as fracture of the femur, and attended with permanent deformity and serious physical shock, followed by permanent impairment of health.

*Fracture of Fingers and Toes.*—Fractures either of digits or phalanges, is attended with loss of time proportionate to that resulting from fracture of arm, but function is sooner restored and approximate amount of such damage not to exceed one-half that of the latter.

5. *Dislocations.*—This class of traumatisms is quite rare in railway practice, and so seldom attended with permanent results that we may with propriety pass it over, only calling attention to undiscovered or neglected cases which, "in spite of" the ignorance or neglect of the surgeon must be considered as proximate, and damages attach by reason of perma-

nent deformity and disability. An exception should also be made of dislocation of the astragalus which is often attended with deformity.

6. *Amputations.*—In this class of traumatisms the same circumstances and conditions prevail as in fractures, with reference to loss of time, suffering, etc. But as regards the degree of permanent disability and approximate effects upon the expectancy of life, there is manifestly a difference especially in the latter. It is a well-known fact that amputations cut short the expectancy of life. Reflex conditions are common in stumps, which often produce serious nervous and even psychic disturbances. Amputation is the opprobrium of surgical art, and beyond the impairment for manual labor there is an element or sense of opprobrium, a mental anguish over the existing deformity. In many such cases I have observed a hypersensitiveness so great that upon the slightest manifestation of pity, sympathy, or any allusion whatever by a warm friend even, he would forfeit their esteem. The approximate amount of permanent damage for earning a livelihood, resulting from amputation of the arm or fore-arm is taken by the Pension Department as a basis of all traumatisms and diseased conditions as well; from \$30 to 45 per month being the pension allowed for such loss of arm or fore-arm. In this Government award other conditions, or resulting conditions, are not followed by any farther increase of pension, the minimum pension named being considered the equivalent of allowance for total disability, unless it be in cases of total helplessness where an attendant is required; and in that case the amount allowed is \$72 per month. From this, allowing for the conditions recognized by the courts quoted in the beginning of this paper, it would be comparatively easy to approximate the total amount of damages in any case of traumatism, taking into account conditions mentioned heretofore and also the normal expectancy of life.

The approximate and just monetary award in other amputations does not differ greatly, except as regards expenses in attending them. The disability for the performance of manual labor would depend somewhat upon the avocation of the claimant, but the loss of an extremity, either upper or lower, is usually considered as total disability. Amputation of digital or phalanged extremities should be considered, as the grasp of the hand is impaired, and the symmetry of the member destroyed; but as compared with the loss of the arm, the damages would be very small, unless all or most of the digits were amputated, when the damages would reasonably be nearly as great as from the former.

7. *Contused and Lacerated Wounds.*—These, the most common of all railway traumatisms, are often serious in character and often complicated with injury to or fracture of osseous structures, or injury of periosteum resulting in necrosis, and in many instances injury of peripheral nerves causing reflex conditions in remote portions of the body or brain. Unless there be actual loss of tissue, we do not, under modern asepsis, often meet with such conditions resulting from traumatisms to the soft tissues. Tetanus and tetany, now known to be of septic origin, are almost unknown where sepsis is prevented by efficient antiseptic agents. It is obvious that the railway companies are, in an economic sense, greatly the gainers by the wonderful results of such antiseptic treatment, as the expenses attending the modern treatment of lacerated wounds are not one-fourth what they were but a few years since, and permanent injuries resulting are far less frequent.

In any case of crushed or lacerated wound, we must observe the same conditions as in the case of compound fractures, considering the loss of time, etc., and taking into account the deformity or impairment of function; and also the uncalled-for damages resultant from the mistake of the company of employing back numbers to do modern surgery.

We would consider scalp wounds attended with fracture as serious, for the reason that they are so often followed by serious results. Aseptically treated, these wounds when not attended by fracture, heal rapidly and seldom become elements in cases of claims for damages.

8. *"Entasis" or Sprains.*—We find this class of injuries to be about 10 per cent. of all railway traumatisms, and will be called upon to consider them by reason of the permanent disabilities often resulting. Sprain of the knee joint often terminates in inflammatory conditions, followed by destruction of the joint and permanent deformity or loss of limb. Damages should be apportioned in such deformity as in other cases of impaired function, and so on. Sprain of the ankle joint we often find a source of permanent impairment, the same conditions pertaining to the wrist joint with its ligamentous and complex articulation. Rupture of tendons

or muscular tissue from sprains is met with, resulting frequently in permanent impairment of function but not often in serious damage.

9. *Injuries to the Eye and Ear.*—These we will send to the specialist who is employed, or should be, by the company, as "Uncle Sam" sets them the example.

10. *Rupture, or Acute Hernia.*—This is of infrequent occurrence, being met with in only about 2 per cent. of all cases of traumatism. Damages could reasonably and approximately be determined as indicated in amputation of the arm, from amount awarded by the Pension Department.

11. *Scalds and Burns.*—This class of injuries occurring only in 3 or 4 per cent. of all cases, is often of serious character, and usually fatal. The super-heated steam of the engine boiler is a terrible agency, and where a surface of the body equal to one square foot comes in contact with it, for sufficient length of time to scald the true derma, death of the victim follows. In cases not so seriously burned, great suffering results, attended with severe nervous shock and followed by serious deformity. If the face be the portion receiving the impact of the steam, as is frequently the case, if recovery take place the patient is subsequently found to be greatly disfigured. The method of "blowing out the ashpan," is often attended with terrible results to the engineer or fireman, as I have myself in several instances observed. In determining the approximate amount of damage in these cases we will usually only be called upon to consider the disfigurement, impairment, or loss of eyesight, as the shock from burns is not, usually, attended with permanent neuroses. Many other conditions might properly be mentioned, but I have only sought to refer to the traumatisms commonly met with.

This will conclude my consideration of this important subject, and I am fully conscious that I have very imperfectly fulfilled the task allotted me: "*The Best Method of Approximately Determining the Amount of Damage Sustained by a Traumatism, from a Monetary Standpoint.*"

#### DISCUSSION.

DR. JOHN E. OWENS, of Chicago—I find very little to say at this moment, except perhaps to express my appreciation of the value of this paper. It is comprehensive and covers a great deal of ground. It has been carefully prepared, and I have been very much instructed by it. At the same time in the discussion I would feel myself involved in an inextricable network were I to state the method of determining from a monetary standpoint the result from traumatism. There are so many elements involved that each case must serve as its own, or should be a problem of itself, and must be decided upon its own merits. I presume that the only discussion I ought to enter upon would be that from the standpoint of a surgeon or physician. At all events, so far as an adjuster is concerned, I have had very little experience, and I have never encouraged it among the surgeons on the lines of roads that I happen to be interested in. There are so many legal points involved in the case, so many circumstances that belong to the train service that I find, and I think others find, it would be impossible for them to wade through all and arrive at a just legal conclusion, to say nothing of the conclusion the doctor or physician himself might arrive at. When I asked a rather prominent gentleman something in reference to such matters, he said: "Is this meeting one of claim agents, of lawyers, or surgeons?" I told him in many cases he would find all these combined in the doctor, and I believe that is the case in some few instances. Again, I believe that the two positions, the position of adjuster and the one of surgeon are somewhat incompatible with each other. If it is known that the surgeon is not an adjuster, the patient unwittingly and sometimes more palpably shows animosity which interferes with the easy adjustment of the case. At the same time we can do considerable. The surgeon or physician, if tactful, can do very much in disabusing the patient's mind of these various conditions of exaggeration and influence brought about by cupidity, which the adjuster or certainly the attorney for the company can never do.

We never know what influences have been brought to

bear on patients (plaintiffs) before they come into the court room. To show you I am right in this matter, I will venture to read some letters which I have secured. (These letters were then read.)

Since being notified that I was to discuss this paper a little, I have talked the matter over with some gentlemen who are very familiar with the workings of the question, and I will read just a few extracts of a letter from an attorney connected with a railway:

"Adopting the language of the clinics, every traumatism may be said to be manifested by two distinct sets of symptoms; the one objective, sensate; the other subjective, insensate; and the law following in the footsteps of surgery allows compensation for each of these manifested effects, combining the two in order to ascertain the extent of the physical impairment as a basis of determining the actual pecuniary loss which to some degree of correctness may be estimated, and at the same time looking at the subjective symptoms as a direct basis for compensation, the amount of which is wholly speculative, conjectural, and is measured only by human sympathy, the only check against which, if indeed there is any check, is what is called judicial discretion, which is but the sympathy of the judge set against the sympathy of the juror.

"Thus the compensation which the law allows consists of two distinct elements: One a compensation and re-imbursement for pecuniary loss; the other a *solatium* wholly speculative in amount for physical pain and mental suffering.

"Here the law in this, as in all other classes of wrongs and injuries, seeks to reimburse the injured person in the pecuniary loss which follows as the natural and proximate result and consequence of the injury. Into this measure of compensation, decreased earning capacity, loss of time, money expended about the treatment and cure of the injury and restoration of the physical condition and all extra expense made reasonably necessary and proper by the injury, enter as elements. The reasonableness and propriety of the expense will vary and be dependent upon differences in the circumstances and conditions of different persons according as they are refined, cultivated, intellectual, accustomed to the conveniences or elegancies of life, or as they may be brutish, coarse, ignorant, accustomed to hardships and poverty.

"The locomotive engineer who earns by his occupation \$2,500 a year, loses both hands in a railroad wreck under circumstances which render the railroad company liable. How much should the company pay on account of lost earning capacity? The simple answer in the abstract is: "He should have such sum annually as equals the difference between the sum he would have been capable of earning each year during his life had he not been injured, and the sum he is capable of earning during the same period. How much is that? How long would he live? If he would have lived to be 80 uninjured, yet how many years and up to what age would he have been capable of earning \$2,500 a year as an engineer? Being engaged in such dangerous occupation, what was his life expectancy? Or being so engaged, what was his expectancy as to immunity from injury as one of the risks of his employment incapacitating him as an engineer and for which the railroad company would not be liable?

"The theory, the abstract is easy. The question in the concrete, the present sum of money to be paid is the difficult thing to be answered.

"It has been contended by some, and even by some judges, that such a sum of money should be at present paid as when invested at the usual legal rate of interest would produce an annual sum equal to the annual loss in earning capacity. According to this method, if the annual difference should

equal \$5,000 and the annual rate of interest 5 per cent., a jury should award \$100,000 present damages. Yet this is obviously unjust, for the reason that the injured person during his life would not have received as much as in all probability he could have earned uninjured, and at his death his heirs would be entitled to the principal which the ancestor would never during his life have been able to accumulate.

"In my judgment the best method of determining this question, should be based upon, but in some respects different from the method of estimating the present cash value of dower estates, life annuities, or annuities for other fixed periods. This method is the result of calculations as to the present value of a fixed annual value or sum continuing for an uncertain period. The probable duration of the period being estimated from the life tables. The method is fully explained in the Wigglesworth Tables, and others.

"Thus a woman 40 years of age having a dower estate valued at \$1,000, the present cash value of such an estate is only \$630.

"In estimating annuities and dower interest, both terms of the proposition are fixed, one, however, being uncertain as to duration. In the question now discussed neither term is fixed for the earning capacity of man is affected, strengthened or impaired by many other causes than his physical and mental condition. And besides, while we have life tables showing the probable duration of the natural life, hence an estimate of the present sum to be paid an injured person based upon the existing tables would be much wider from the mark than on the estimates for annuities and dower interests.

"In the innocence of my youth I used to think that 'it is always the wounded bird that flutters,' but since I have been an attorney for a railroad I have seen full many a bird flutter that was not wounded. As to any basis, method or standard by which the amount of compensation to be allowed for physical pain and mental suffering may be even approximately measured, we are utterly at sea. The courts in allowing compensation for pain and suffering have arbitrarily and widely departed from the rules of law applicable to the measure of damages in all other cases. While this departure from the ordinary rules may meet the approval of our sense of humanity, it can not be reconciled with any correct principle of law, except in cases where the injury has been wilfully or wantonly inflicted in which punitive damages or smart money is allowable not as compensation to the injured person, but rather as a punishment to the wrong-doer.

"That the pain exists at all is a fact known alone to him who suffers it, while others are left to believe or disbelieve its existence accordingly as they may judge of the manifestation thereof by the alleged sufferer; who can say whether my tooth aches or that I suffer constant pain in the spinal column increased by finger pressure, without relying on the evidence of such pain emanating from myself alone? These injuries, these elements of damage, the symptoms of which are purely subjective, are indeed the most dangerous class of cases to railroad companies, and to them railroad surgeons should give careful attention in order as far as possible to detect malingering.

"There is no 'best method' for determining the compensation that should be allowed for physical pain and mental suffering, for the allowance of such compensation is wholly without method, measure or standard of any kind, beyond the varying and uncertain emotions of the human heart."

I believe myself that from a doctor's standpoint, I might venture to detain you just a second more by saying that for the railway surgeon the following points seem very essential, and it is incumbent upon us:

1. To have a due appreciation of the cause, nature and extent of the injury.

2. An acquaintance with the pathology and prognosis of similar injuries where there is no possible liability, and where cupidity can not become an element in the problem.

3. A careful management of the injury according to the most approved methods.

4. An opinion based on the known pathology of the injury.

5. The exclusion of all litigation and other extravagant, unique and inexplicable symptoms which find no foothold in our more fixed medical and surgical literature.

Giving an opinion upon such a basis would enable our attorneys and our claim agents perhaps to more easily arrive at a proper settlement.

DR. W. H. MEYERS, of Myersdale, Pa.—The discussion brought out this point, in reference to men being under the influence of liquor, saying that the essayist was correct, but that some men played the part of impostors and were not in any way entitled to pay from the company. The Baltimore & Ohio Railway Company always pays and settles its cases promptly and liberally. The following is the history of the case:

A. J. I., married; aged 49; residence Uniontown, Pa.; claims to be injured internally in abdominal region in New Castle (yard) Pa., wreck. He says he passed blood from bowels at stool in water closet in ladies' coach; passage examined by Drs. Gildner, Meyers and W. H. Meyers, Jr., and found no blood on examination in water closet nor in snow under water closet. The statement made by Mrs. Amanda Jacobs, 6135 Sangamon Street, Chicago, and others was that he did not complain of any injuries until after men returned from looking at the wreck. Drs. Gildner and Meyers found nothing apparently wrong, except that he was under the influence of some stimulant. Dr. Gildner and Dr. Meyers made a personal examination of patient, with reference to his pulse, examining his eyes, resorting to auscultation, percussion, etc.

DR. REED—The question, as stated in the program, the best method for approximately determining the amount of damage sustained by a traumatism from a monetary standpoint, is one that affects every railroad company in the country. It is one in which the railway surgeon is always called upon sooner or later to determine, and is one in which he is often placed in the most embarrassing position. If he is called upon to testify on the witness stand, this is one of the questions which the attorney for the defense will always ask, either privately or on the witness stand. It is one in which if there is no suit the surgeon is again asked by the company to settle. Now, the question of getting at this matter is one I think of great importance. I have written to quite a number of surgeons who have had experience in this matter, and I at one time prepared an editorial, or rather a paper on this subject, for *The Railway Surgeon*, in which I tried to set forth some of the principles that should govern railway surgeons in estimating these damages. After discussing the matter with the manager of *The Railway Surgeon*, who had supreme control, it was decided that it was not advisable for us to discuss a question of this kind. Now, it does seem to me, gentlemen, that while this is a question that is of serious importance, it is right that we should discuss it. We have no right to turn our back on a fire that is destroying our building. It is our duty to put it out if we can. We, as railway surgeons, can not afford to go on the witness stand and testify to anything that is not the truth. We can not afford to perjure ourselves for our companies, neither can we afford to go on the witness stand and testify in such a way as will destroy a just claim. It is our duty as railway surgeons to testify as to the truth, let it be what it will. Then comes the question, How shall we determine the value of an

injury? Take, for instance, a party who is injured in the arm. We will say there is a Colles fracture, and that the company was liable for the injury. Now, how are we going to determine how much that is worth, and at the same time be fair to the patient and to the company? This is the question that has been brought out in this debate, as I understand it. It seems to me we can, by accumulating facts which every railway surgeon has an opportunity to do, arrive at a general conclusion as to the value of a certain class of injuries. How are we going to do this? We can not apply any ironclad rule and say that a fractured arm is worth \$500, or that a certain limb is worth \$1,000, because there is a gradation of variation. One man's arm may be worth to him \$5,000, while another man's arm may not be worth half that much. I am speaking now of the money value in different men. Why? Because in one case a man may have an occupation whereby he must use one arm more than another, or perhaps any other member of his body; while in the other case, the man may be able to continue his occupation, making just as much money as he did before the loss of the arm. These are points that have to be considered, and the best method of arriving at them is what we want to attain if possible.

It has been my custom for the last fifteen years to take into consideration first the condition of the patient, and the age. Age has something to do with value. A man, 21 years of age, has an earning capacity, so far as age is concerned, superior to a man of 70 years of age. That would be one factor. We should take into consideration the earning capacity of a man or woman, as the case may be, relative to his or her occupation. One laborer, we will say, earns \$500 a year, while another man of higher attainments will earn \$1,500 a year. Another will earn \$2,000 a year, and still another \$5,000. If that party is maimed in such a way as to interfere with his earning capacity, to what extent is he damaged, and that should be a factor in considering the damages sustained by the traumatism. Then again, we must take into consideration in addition to the earning capacity, the expectancy of life which has some bearing on age. Furthermore, we must consider the amount, as the doctor stated in his paper, of actual pain and injury that the party has sustained through traumatism; in other words, the amount of suffering. What is that worth? I have been in the habit of rating a certain amount for suffering sustained by the pauper, just the same as it would be for the millionaire. One would suffer as much as the other, so that the rating is equal or on a level. But the earning capacity of the pauper would be entirely different from that of the millionaire, or of some one whose capacity for earning would be \$1,000 or \$2,000 a year. Then we must take into consideration the amount of time lost and the value of that time rated on the man's earning capacity, which should be based on his age, his salary, or the amount he could earn if he was not injured. I think if we take these matters into consideration we can approximately at least set a value on a broken arm, based on these three leading principles: Age, value of earning capacity, and the amount of damage that we would fix for the actual amount of pain sustained. But, at the same time, when we go before a jury, these questions are generally fixed by this body, and it is hard for us, with all the care we may take, to go before a jury and convince them as to the fixed amount of value a certain party should have for a certain injury. But at the present time, I think the legal departments of our railroads are largely coming to the idea of settling these questions without going into court, as far as possible, and here is the place where you can use these principles to the best advantage. You can rate up a man's injury approximately close to its true value, so that you can say conscientiously of this man that he has a fractured arm,

that he has been off duty for six weeks, and that his time is worth so much a week. We can say there is a certain amount of permanent injury that is worth so much for the balance of his life, taking into consideration his earning capacity. By this method we can arrive at an approximately fair estimate. We should, as railway surgeons, consider these points and keep careful records of our cases. I have records of cases for over fifteen years. I know the length of time the party has been off duty; I know his earning capacity, and know what we have paid him. By taking the average case of fracture of the arm, the average time lost, the average value of time in a certain class of cases, you can estimate the amount within a few hundred dollars of the actual value of each party's time. The main question to settle is this, Should a party be paid for the actual amount of pain they have had for a certain class of injury. One man having a fractured arm will suffer much more pain than another of the same character, because he may be a sensitive nervous man, and consequently suffers far more because of that than the other man who perhaps has more animal nature, and is less sensitive from a nervous standpoint, yet each one loses the same amount of time. So here is a gradation again. I hope we shall hear more on this question. It is one that has not been discussed to any great extent. We can find no literature on the subject except instructions given by accident insurance companies. I feel that it is a subject of sufficient importance for us to discuss and if possible fix a schedule for our guidance in this class of injuries.

DR. ARTHUR D. BEVAN, of Chicago—I think we are treading on dangerous ground. One of the dangers to the good name of railroad surgery is the danger of allowing railway surgeons to be made tools of by the claim agent department and by the law department. I am sorry if I have to differ from the author of the paper and the past speaker, but I should say distinctly that this is not a medical question. It is purely a legal question, and one which belongs to both the law and claim departments. We should not, if we begin our Association with the motto that it is for "the higher order of railway surgery," allow anything of this kind to creep into our work. I may say to you emphatically that I do not believe we should allow railroad surgery to be prostituted to the work of handling this class of cases. We have nothing whatever to do with settling for an injury to a limb or as to the value of loss of life. I speak with some preparation upon this subject because I was down for a discussion of the paper on the best method of determining the value of life where death was caused by accidental means. I have taken some pains to run over the work with some of my legal friends, and without exception they have agreed with me that it is a purely legal question, one which cannot in any way be discussed in a purely medical society. I do not believe that we can do anything more important, or take any more important step in placing this Academy of Railway Surgeons on a high plane, than by recognizing the fact that as railway surgeons we have nothing to do with the legal or claim department. When a man is injured you simply state to the claim or law department the outcome of the injury, and the length of time it will last. It is not for you to determine how much a jury, or judge, or company will allow him as compensation. I therefore wish to take a decided position in regard to this question. There are many chief surgeons here and we ought to discourage the handling and settling of claims by railway surgeons. We ought, on the other hand, to demand that the law and claim departments continue to take these matters in their own hands. Railroad surgery is believed by the public to be notoriously partisan. Your testimony on the witness stand is taken with a great deal of incredulity simply because we allow ourselves to be dragged into this kind of work. We ought to take a decided

stand in this, that all papers read and discussed on these subjects should be recognized as outside of our sphere, as simply being read and discussed because they are of general interest just as any outside matter might be to the physician.

DR. C. K. COLE—I agree with Dr. Bevan as to the relation of the railway surgeon to the patient, the legal department of the road, and to all concerned, and I believe that is true of Dr. Harnden, and the position taken by him, as also Dr. Owens who opened the discussion. The remarks of Dr. Bevan are remarks which have been heard before and on lines which have been somewhat fully discussed in similar organizations to this, and I think we are fully agreed that we should not be partisan, that we should not be biased, that we should give testimony which will be accepted and acceptable to the court and to all concerned, and yet we can not get away from the fact that we have a dual function as railway surgeons. We are executives of the road we represent, but that does not deny to us the privilege of giving fair and impartial testimony. As witnesses we are judicial and I believe, as a matter of fact, we are impartial and non-partisan. I consider this a very vital question for this Academy to discuss. I can not conceive of any more important subject and yet it is to my mind a purely medico-legal question. I take it, Mr. President, that it is so important a subject that if we discuss it fully—if we could take the paper read, have it edited and condensed with the discussions already had, we will evolve facts which will enable us to approximately value life in connection with this class of accidents or cases injured upon our railroads. I had it in my mind to make the proposition that the paper and discussions should be epitomized with a view for further discussion at a subsequent meeting. I had intended to discuss the paper itself, but Drs. Owen and Reed have gone over the ground so fully that I hardly feel warranted in consuming the further time of the Academy to say any more than I have.

DR. W. H. ELLIOTT—In the main I agree with what Dr. Bevan has said on this subject, but I do not think the line of the surgeon's duty in this case has been as clearly stated as it might be, and I rise for that purpose. In the law department of the road I represent, they do not ask the surgeon to take any part at all in settling the claims—in fact, he is not allowed to do it. In the directions given to the surgeons, it is distinctly stated that the surgeons have no right to settle claims, nor to make any promises on part of the company, but they are expected to use all honorable means to prevent law suits. Now, I believe the duty of the surgeon is just this: I do not think it is his business to estimate the money value of an injury. I think that is outside of a surgeon's usual capacity, and furthermore, I think if done it will compromise his position. What I conceive to be the surgeon's duty is this, besides stating the extent, duration, and the exact conditions of the disabled party, that it is a medical question, that he should state clearly to both the law and claim departments of the road he represents just how much the injury, if it is permanent, interferes with the man's earning his livelihood, not how much money he can make a day. The surgeon should give the law and claim departments some basis so that they can make their figures. They are to make the figures, and you are to give the information upon which they are to make a settlement. Then too, the medical man is the only one, I think that can state fairly what has been the amount of suffering in this or that case. He has watched by the patient's bedside, gone there perhaps at midnight to give a hypodermic injection, and he knows, he is accustomed to estimating suffering. He is not a doctor if he does not estimate suffering and try to relieve it. He can state, if the patient is a highly nervous subject, that the suffering has been intense, while

a laboring man, whose injury seems to be a severe one, suffers much less as compared with the other patient from what you would expect from such an injury. After giving an opinion on these two points the business connection of the railway surgeon with the case ceases.

DR. F. H. CALDWELL, of Sanford, Florida—Ten years ago I told my superintendent when we had a hospital system on the road, that I occupied a dual position. I was an employee of the company and an employee of the employees. They pay so much a month to the hospital fund. It was not a charitable institution, and they had a claim upon me as well as the company, and I declined to take any part whatever in the settlement of claims. It would injure my influence for good with the employees, and it would detract from my confidence which the company had in me, and I did not think I could consistently take any action in this way. The president and superintendent of the road sustained my position and since that time I have had nothing whatever to do with damages. The method pursued by the company I represent is this, that as the papers come into my office with the request for information relative to the nature and extent of the injuries received, I indorse the extent and probable outcome of the injury and return them to the office, and that is the last I know of the matter. The rest is settled by the claim department. I showed Mr. Plant this program, but he had already received a copy of it. I told him of the importance of this discussion, we went over the program together, and he said any discussion should be *sub rosa*. "It is all right for you gentlemen to discuss this matter among yourselves and have a fair judgment as to the amount of damages that should accrue." Dr. Cole has made a point which I think is a good one, that if this discussion should be published broadcast, and an anti-railroad attorney should get hold of it, he would make good use of it before a jury if any of us are called upon (which we are frequently) to testify in cases of this kind. I agree fully with those gentlemen who say that this matter should not be published broadcast; that if we do as Dr. Reed suggests, viz., get up a schedule, if there is any important case on hand, it will be brought before a jury and used against the company. The surgeon's duty to his patient is to get him well, if possible. If called upon to go before the court, his duty is to "tell the truth, the whole truth, and nothing but the truth;" whether it be for or against the company he represents. I tell you, gentlemen, that the onus which comes upon us as witnesses before a jury is due to a very large extent to the fact that it has been demonstrated that a large number of surgeons—I do not say any of the gentlemen present have done it—have shown their preference on the witness stand in favor of the company. The sooner we realize that fact, and the sooner we realize the fact that a plain statement of facts made before a jury is the best, the sooner will our testimony be given weight.

DR. LEMON, of Denver—There is no doubt but that all of us as railway surgeons, when cases get into court, have to give opinions. I have made it a rule, which I consider a good one, to confine my statements to the physical signs alone. I always object to answer the question regarding pain. I do not believe any of us can determine how much pain one patient will suffer over another. That is something we can not estimate at all. That is something we should ignore and simply decline to answer. I have frequently said to lawyers, that is something I can not estimate, but the other signs I can.

DR. REED—I desire to make one correction. Dr. Caldwell said I spoke of a schedule of prices. I did not lay down a schedule of prices, and if that impression was conveyed I did not intend it. I meant a schedule of certain things, as it were, that should govern our judgment as to the amount of value, as, for instance, the age, the occupation of the party, and damages, what is the actual injury sustained; that we should be able to designate how much each one should be given according to the patient's situation. I did not mean to convey the idea that we should have fixed prices. We would have to fix the price on principles, and not on any ironclad plan.

DR. HARNDEN—I think the paper has been misinterpreted somewhat by some of the gentlemen, in that I disclaimed any intention in the paper of our becoming claim agents. I would like to know if there is any gentleman in this room who acts as claim agent or does a claim agent's business. I stated in the paper that we as railway surgeons are to act as advisers, and are not expected to take the place of claim agents.

(To be continued.)

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE . . . . . \$5.00

SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, FEBRUARY 9, 1895.

A PROFESSIONAL DUTY.

There are certain obligations a man takes upon himself when he enters one of the learned professions. Among the most important of those duties is that of advancing the general good of the profession itself. Every conscientious physician who loves his work for its own sake, must feel that to a large extent his own standing in the community is measured by the general standing of his profession. To make that profession powerful, to make its influence felt in all directions, in which the profession have an interest, organization is a necessity. We must unite for general advancement, general encouragement of our interests, and mutual improvement. Under what banner can we fall into line more appropriately than under that of the AMERICAN MEDICAL ASSOCIATION?

Membership in that ASSOCIATION, is based on correct local standing. No one not a member of a State or local medical society in good repute can become a member of our already great ASSOCIATION. It is therefore evident that the local society and the State society are fostered and sustained by the ASSOCIATION.

Many gentlemen applying for membership in the ASSOCIATION, have been obliged to wait until they had first joined their local society. This is the practical effect of the law, but *there are hundreds of physicians who are not aware that they may join the ASSOCIATION by simple application, properly certified by the officers of their local society.*

Will our members each for himself, look into this matter in his local society, and by inquiry find out who are members? Let this matter be pushed in the local societies; the JOURNAL will be made better and better, larger and larger, in equal pace with

the growth of the ASSOCIATION. The JOURNAL has already grown to be one of the largest, but we are yet far behind the *British Medical Journal* and the *Semaine Médicale* in the journalistic race for pre-eminence. The medical profession of America more than any other, should have the greatest journal. It is within its capabilities, and within easy reach. Jealousies should be sunk in this matter, for no private publisher can be able to gather the whole profession under his interest, nor so far as we are aware, do any of them expect it.

We urge our members to do their whole duty in increasing the ASSOCIATION membership, at every meeting of their local society, and in six months the work will have been measurably accomplished.

If there is personal feeling, let it slumber; if there have been disappointments, let us forget them; if we want changes in form or matter, let them be urged on the floor where all have an equal voice.

Let us unite as a professional brotherhood, bound by every tie of patriotism, and professional honor!

RELATION OF GOUT AND URIC ACID.

DR. ALEXANDER HAIG, (*British Medical Journal*, Dec. 8, 1894) gives us an extremely simple explanation of the relation of gout to the excretion of uric acid. He finds that when the latter substance is taken into the stomach it acts as a decided stimulant, producing a feeling of buoyancy; this condition is succeeded by depression, disinclination to exercise and headache. The first of these conditions is accounted for on the theory that the uric acid lessens the alkalinity of the blood, and hence this substance is not taken up from the tissues, so that for a time after its ingestion the circulation actually contains less uric acid. Later, when the alkalinity of the blood is restored and uric acid again finds its way into the circulation we have depression and malaise.

DR. HAIG on these premises gives us a theory in explanation of the fact so often noted that many gouty persons improve on a meat diet. This he thinks is due to the free uric acid which such substances contain, and which for a time secures temporary amelioration of the symptoms only to be followed by an aggravation of the disease.

We confess that this view of the matter, attractive and simple as it seems, does not appeal strongly to our judgment. In the first place, if uric acid is absorbed from the tissues, why does it not lessen the alkalinity of the blood, the same as when taken up from the stomach? We do not think that the writer has answered this query. Again, the improvement often noted in gouty subjects, when on a meat diet, is frequently due to the fact that the diet, as a whole is very much lessened.

The logical deduction from DR. HAIG's theories would be a vegetable diet for gouty subjects, but we

know that many patients are not benefited by such regimen, but on the contrary improve when vegetables are restricted.

The truth is that a number of toxemias are dependent upon perversions in the digestive tract, which clinically can not be differentiated from the ordinary forms of uric acid poisoning, and these are often greatly modified by changes in the quality of food. Some patients can not digest fats, others must avoid starches and sugars, while still another class can take proteids only in certain forms.

In the treatment of the uric acid diathesis, too little attention has been paid to the absolute quantity of food taken. It is of little consequence what diet is given, provided the digestive tract is healthy and free from fermentations. To avoid uric acid production we need only reduce *luxus consumption* to the vanishing point.

#### POLLUTION OF NAVIGABLE STREAMS.

House bill, No. 8481, which provides for the appointment of a Commission to investigate the subject of the contamination of such lakes and streams as are the source of water supply to more than one State, still slumbers in committee so far as we are informed, and a petition was introduced into the Senate February 20, from the Pennsylvania Board of Health praying for the passage of the bill.

We are not advised of the exact text of the bill, but it is evident that some measure of this kind should be enacted. Were there a Department of Public Health, all such investigations would naturally fall under its scope, but in the absence of such a Department, special legislation is necessary.

The British Rivers Pollution Commission, instituted by Parliament many years ago, set an excellent example of what such a commission could do to advance the interests of public health, by ascertaining facts and making recommendations for the securing of pure water supply. In this country, work of this character has been done by the Massachusetts State Board of Health, the Illinois State Board of Health and perhaps others, but this work was necessarily limited to State waters, with exception perhaps of the investigation of the waters of the Illinois River, which emptying as it does into the Mississippi, was an object of some solicitude to the good people of St. Louis and other places in Missouri.

But it is obvious that the water of such rivers as the Ohio, and the Mississippi, where the river itself constitutes the State boundary of many States, should be investigated by impartial authority. That authority can only be found in the general government, and as the population deriving water supply from rivers is steadily increasing, there is a more pressing need for action each year.

*Let there be created a Department of Public Health!*

#### LICENSE OF HOSPITALS.

Moved thereto by the inadequacy of existing laws and ordinances to deal with the rapidly growing brood of "faith curists," "Christian scientists," *et hoc genus omne*, and more directly by the difficulty of suppressing a notorious fraud, the "REV." JOHN ALEXANDER DOWIE—a "faith healer" who has been successively, but not successfully, tackled by the State Board of Health for practicing medicine without a license, by the city authorities for maintaining an unsanitary establishment and concealing deaths occurring in his "tabernacle," and by one or more of his victims for obtaining money under false pretences—the Health Commissioner of Chicago, DR. ARTHUR R. REYNOLDS, has succeeded in procuring the enactment of a municipal ordinance the enforcement of which should make short work with this tribe.

It forbids the establishment or maintenance within the city limits of any hospital, other than those of the United States, of the State, the county and the city, except upon license of the Commissioner of Health, who is empowered to make "strict inquiry" into the location of every hospital, the purpose for which it is conducted or maintained, its fitness for such purpose, the nature and kind of treatment given and the qualifications of its chief physician or surgeon under the laws of the State; and to issue, refuse or revoke a license upon the facts disclosed by such "strict inquiry." The chief physician or surgeon or superintendent shall make a report to the Commissioner on or before the fifth day of each calendar month, showing a complete record of such hospital during the preceding month, including the number of inmates received, discharged and died during the month, the causes of deaths and such other information as may be necessary to an intelligent sanitary supervision of the establishment.

For the purposes of the ordinance a "hospital" is defined to mean any place used for the reception or care, *temporary or continuous*, of the sick, injured or dependent (including women awaiting confinement) or used for the treatment of mental or physical disease or bodily injury. Under this definition it is held that "faith cures," quack "dispensaries" and "institutes," "massage parlors," "anatomical museums," lying-in establishments, opium and drink "cures," and kindred institutions must obtain licenses and come under the supervision of the Department of Health, or cease business.

The beneficial scope of the ordinance cannot be overestimated. Its judicious enforcement should largely reduce the aggregate of swindling under the guise of medical and surgical treatment, of the notorious immorality of the "massage parlor" and of the butchery of young women and infants in the dens of procuresses licensed as midwives. Reputable establishments will no doubt welcome the enactment, and it may be profitably copied by other communities.

## MEDICAL COLLEGE "NOTES AND COMMENTS."

By the omission of a reference number preceding the Atlanta Medical College, in the table of Medical Colleges on page 60 of the current volume of the JOURNAL (issue of January 12) the "Notes and Comments" on pages 61 and 62, are made to refer erroneously to the respective colleges by one minus number each. Thus, the "note" numbered 9 should refer to the Atlanta Medical College, and "note" 10 to the Southern Medical College and similar transpositions throughout. As, for example, the note to the Woman's Medical College of Pennsylvania, numbered 36, which reads: "Partly due to the fact that we began our compulsory course next year," etc.; the note numbered 37 belongs to this college and reads: "The recent reduction in the number of students was probably due to the lengthening of the course of study to four years and the advance in the standard of entrance requirements adopted by the college." As the Registrars of one or two colleges—DR. WILLIS G. TUCKER, of the Albany, and DR. R. F. RUTTAN, of the McGill—have been kind enough to point out, the article will be used for reference and no usual correction will be noticed; therefore, and in compliance with requests from others interested, the table and notes will be republished in full in an early issue of the JOURNAL with the comments identified by the college titles.

The returns of the Albany Medical College, made Nov. 1, 1894, were noted at that time "not complete." Under date of the 1st inst., DR. TUCKER furnishes the revised list of attendance, as follows: First-year students, 84; second-year, 54; third-year, 58; total attendance, 196—as against 173 for the last previous session.

DR. RUTTAN, Registrar of the Faculty of Medicine of McGill University, also furnishes a revised list of the same date, as follows: Total attendance, 401—there being 121 in the second year, and 72 in the fourth year; the total attendance at the last previous session was 350.

## CORRESPONDENCE.

## The Practical Importance of Well Established Facts in Therapeutics.

To the Editor:—In order to explain the undeniably miraculous effects of the large dose of alcohol by which on the Alps I was restored from a condition of profound general prostration to one of ability and health, Dr. Davis is obliged to ignore his so-called established facts as regards depression of the nervous system, the diminution of muscular force and the alteration of blood consequent on defective oxygenation and retarded metabolism, and to be driven back on its supposed anesthetic action on the partially sensitive vagus and the insensitive vasomotor nerves. He thinks a dose of chloroform or ether would have produced the same effect. I do not think so. With chloroform I should have been put to sleep never to awaken again. If my vagus and

vasomotor system required a sedative it must have been supplied by healthy blood, for as soon as the circulation was restored and my extremities became warm, the sickness disappeared and my muscles recovered all their power. But the established facts of Dr. Davis are the effects only of the misuse of alcohol. They are seen in perfection in the drunken man. Before the days of chloroform I was present at an operation when the patient was carried from the operating table unconscious from the supposed effect of the shock. He awoke some hours after and to the astonishment of his attendants he asked when the operation would begin. He had fortified his courage by a bottle of brandy without the knowledge of the surgeons and the anesthesia was not limited as in my case to his vagus and vasomotor nerves. It should never be forgotten that the effects of alcohol are not solely determined by the quantity administered—a quantity more than sufficient to make a healthy abstainer drunk might be useless in a case of great exhaustion. It is essential that its effects should be estimated less by the quantity than by the condition of the patient. The effects of small doses must be our guide. This subject was treated by Professor Cerna of Texas, in a very exhaustive manner only last year, *Therapeutic Gazette*, 1894). He says: "In small doses alcohol excites the puerperal and sensory nerves, stimulates the cerebral functions, increases reflex action, increases cardiac action by direct contact with the heart itself, causes a rise of arterial pressure, raises bodily temperature, is a conservative of tissue and a generator of vital force and may therefore be considered as a food."

I was an assistant with Dr. Edward Smith and I can personally testify that small doses of alcohol increased the respiratory action and the evolution of carbonic acid. I am also satisfied that to be favorable, the administration of alcohol must be so adapted to the condition of the patient that the established facts of Dr. Davis shall be conspicuous only by their absence.

But let me endeavor to eliminate the question of nervous irritability by the relation of an experience which must be common to the majority of medical practitioners.

Forty years ago the large towns in England were annually devastated by typhoid fever. In 1846, one-fifth of the entire population of Leicester had the fever. We had then no clinical thermometer. The diagnosis had only just been made and was not universally accepted. We had no trained nurses and an abandoned prison was used as a temporary hospital, of which I had charge. At the end of the year I published an account of 186 cases treated with the cold wet sheet and my mortality was 30 per cent. less than that of my colleagues in the hospital. Typhoid fever was then far more serious, far more infectious, far more fatal than it is to-day. The daughter of a farmer living in an isolated farm house in the forest came on a visit to the town. She contracted typhoid fever and was taken home. She recovered, but both her parents had it and the farm servant died of it. The undertaker who lived in the village more than a mile away, caught the disease which spread to his family and neighborhood. A blacksmith lived at a solitary house on the turnpike road. His son, a youth of 12 years, was employed as errand boy to fetch medicines and medical comforts for many of these patients and he took the fever. During this epidemic, I lost half a pound daily for one month. I paid this boy a visit at 10 o'clock at night. He was in the fourth week of the attack. I found his parents sitting by his bedside awaiting his death. He had taken no food for several hours and they said he could not swallow. He lay before me unconscious, his eyes half closed, his lips black with sordes, his tongue like a piece of red mahogany, his pulse imperceptible, his extremities cold, the respiration slow and shallow, the stomach tympanitic and the evacuations were

passing under him. Nevertheless there were no râles in the lungs, and the heart was still fluttering. I sat by the patient for three hours, and I gave him brandy; at first by drops, lest I should choke him and in order that he might rather inhale than swallow it. Then I gave it by the teaspoonful, and before I left he had taken half a pint. Little by little, the circulation was restored, the extremities became warm and life became a possibility. Beef tea and brandy formed his diet for a week and his recovery was eventually complete. Does any one seriously believe that this result would have followed the administration of milk or milk and water?

Now, sir, these were not the symptoms of nervous irritation but of a profound prostration of the nervous, circulatory, respiratory and vasomotor systems and due first to the poison of typhoid, and second to the paralysis of assimilating power and the drain from the intestinal mucous membrane. The alcohol, large as it was when compared with the weight of the patient's body, produced none of its well established ill effects. It did not make the coma more profound. It did not interfere with the absorption of oxygen, it did not retard metabolism and it did not lessen the heart's action. But according to my view and the experiments of Dr. Cerna, it acted as a food which needed no digestion, no assimilative process. Indeed, it was taken when digestion was no longer possible, and being absorbed by the force of mechanical diffusion it was carried into the blood, then sent directly to the heart which it stimulated to increased action, then to the lungs, where it supplied the material for heat production.

Under the stimulus of warm blood every part of the body was excited to renewed vigor. The brain was aroused from its lethargy of impending death, the vasomotor system was forced into new action, the capillaries made blood from the wasting muscles, digestion recommenced, and all these actions were begun and continued under the use of this marvelous remedy.

With respect to the treatment of pneumonia and the effect of alcohol in my own case, Dr. Davis asks what I would say in regard to the case of an elderly physician who was promptly bled and treated according to the antiphlogistic system and nevertheless lived to a ripe old age? To which I would say, that this treatment would have been well adapted to my own case, and that modern physicians have carried their fear of venesection to a ridiculous extent. With dullness and fine crepitation in all the right lung and in the left also to the level of the fourth rib, with excessive rusty sputum, with great congestion and distension of the right heart, and a rapid intermittent pulse, threatening paralysis or as it is now called "failure," there was every indication for the relief which venesection undoubtedly affords. Surely it is wiser and safer to diminish the congestion by this means than to allow the blood to fill up the pulmonary vesicles and to force its way outward through the bronchial mucous membrane. But failing this very reasonable practice, the only way left was to stimulate the heart so as to force the circulation and overcome the difficulty. The administration of alcohol immediately steadied the action of the heart, stopped the intermissions, reduced the frequency of the pulsations, and increased their power; and thus by improving the general circulation the lung congestion was relieved. This was all it did and rest, nursing and good constitution did the rest. But I believe that these would have failed without the assistance of alcohol.

Now sir, I am not so ignorant as to regard longevity as a test of the value and effects of alcohol. Unusual longevity is to be found in every condition and rank of life. Men obtain great ages in spite of bad habits, bad surroundings and injudicious treatment. But I think it worth noting that a physician could hardly use a drug for over fifty years without

detecting some of the evil effects attributed to it by Dr. Davis, if such in reality occurred. I agree with Dr. Davis that the effects of alcohol on the living body require something more than the impressions of an anesthetic patient. I would commend the experiments of Cerna to his special notice. But there are cases like those I have ventured to describe, where the conditions are definite and the results clear and indisputable. In these cases the margin of error is extremely small, and if you should think further illustrations are required, I could certainly prove its value as a therapeutic agent in a variety of morbid states, with the same certainty that attaches to the administration of an ordinary aperient or a dose of morphin.

Yours very obediently,

J. H. STALLARD, M.D. Lond.,

M. R. C. P., M. R. C. S.

#### A Further Contribution to the Subject of Malaria as a Waterborne Disease.

WASHINGTON, D. C., Feb. 1, 1895.

To the Editor:—In your issue of January 26 last, is an article entitled, "A Further Discussion on Malaria, a Waterborne Disease," by Dr. W. H. Daly, Pittsburg, Pa., which treats of malarious waters as a new idea, and at its close gives a bibliography of the subject, beginning with a paper published in the *Medical Record*, September 15 last, and enumerating nine other articles which have appeared since that date. This might lead some of your readers into the mistake of supposing that anterior to that issue of the *Medical Record* this question had received no attention from the medical profession. Medical officers of the Army by their service in various parts of the country have the incidence of endemic disease placed strikingly before them, and it is not therefore a matter of surprise that they should have given much attention to the propagation of endemic fevers. Dr. Daly will find a full discussion of the prevalence of malarial remittents at Fort Bridger, Wyoming, and the grounds on which they were referred for causation to malaria in the water supply of the garrison in an article on "Mountain Fever and Malarious Waters," *American Journal of Medical Science*, Philadelphia, Pa., 1878, n. s. LXXV, pp. 17-43. He will find a full discussion of the subject also in a chapter on the etiology of the paroxysmal fevers in Part III, of the "Medical Volume of the History of the War," and in the Reports of the Committee on Water Supplies of the American Public Health Association, in the volumes of the reports and papers of that Association, as also in the articles "Malaria" and "Water," in "Wood's Reference Handbook of the Medical Sciences."

For several years past, medical officers of the Army have been reducing the malarial sick rate and building up a new reputation for military posts that were formerly regarded as specially insalubrious, by providing pure water supplies for the men under their care. Particularly at certain of the Texas posts has this been done, as at Forts Brown, McIntosh, Ringgold and Clark. The report of the Surgeon-General for the year ending June 30, 1892, makes special mention of this in the following language:

"In the report from this office for the fiscal year ending June 30, 1890, which summarizes the statistics of sickness at our military posts during the calendar year 1889, the remark was made (page 37) that if Fort Brown, Texas, were expunged from the list of our military stations the prevalence of malarial disease in our Army would be greatly reduced. Fort Brown has not been abandoned, but its malarial record has been expunged, with a consequent material lessening of the malarial rate of the Army. During the calendar year 1889, the post had an admission rate for malarial disease of 1,676 and a non-effective rate of 38.58 per thousand of strength. During the year 1891 the corresponding rates were 16.13 and .35. This change which practically alters

the status of Fort Brown from that of the most unhealthy to one of the most healthy garrisons in the Army has been accomplished solely by the use of a pure water for drinking and cooking, an accidental consequence of the introduction and use of an ice machine. Formerly the water supply was pumped from the river into settling tanks and distributed for use. It is so pumped and distributed now for general purposes; but the water for cooking and drinking is obtained from a steam condensing coil connected with the ice machine. Distilled water was introduced in 1890 and the extraordinary change in the health of the garrison can be attributed to nothing else than to its use; for all the other sanitary conditions and surroundings of the post remain as they were during the years of insalubrity and high rates."

Fort Ringgold, Texas, gives corroborative testimony to the foregoing. Here distilled water was introduced in 1886. The post surgeon considers that its use has reduced the sick rate one-half since that time, and that most of his admissions for malarial disease are among troops whose duties have taken them away temporarily from the post. As a matter of published record the admissions at this station have fallen from 2,304 per thousand of strength during the calendar year 1885 to such rates as 562 in 1889, 865 in 1890 and 1,366 during the past year. Respectfully yours,

CHARLES SMART, Major and Surgeon, U. S. A.

### Morphinism in Children.

BROOKLYN, N. Y., Feb. 1, 1895.

To the Editor:—I am desirous of adding to the clinical literature of morphinism in children. If any reader of your JOURNAL has noted a case, and will furnish me details, I will appreciate the favor and give full credit.

J. B. MATTISON, M.D.

## BOOK NOTICES.

**Clinical Gynecology, Medical and Surgical, for Students and Practitioners.** By eminent American teachers. Edited by JOHN M. KEATING, M.D., LL.D., and by HENRY C. COE, M.D., M.R.C.S. Illustrated. Cl., pp. 994. Philadelphia: J. B. Lippincott Company. 1895.

This volume contains articles by the late William Goodell, William H. Baker, Francis H. Davenport, Hunter Robb, Bache McE. Emmet, Barton C. Hirst, Matthew D. Mann, William M. Polk, J. Whitridge Williams, Henry T. Byford, Paul F. Mundé, Herman J. Boldt, Henry C. Coe, William T. Lusk, Chauncey D. Palmer, Chas. Jewett, and John Polak, Edward E. Montgomery, Dudley P. Allen, Louis A. Duhring, and Milton B. Hartzell.

The surviving editor, Dr. Coe, states that owing to the untimely death of Dr. Keating, the completion of the work devolved upon the present editor, who has as far as possible carried out the plans and wishes of his lamented predecessor. While seeking to preserve that coherence which is desirable in a text-book, he has in the main allowed each contributor to consult his own judgment with regard to the arrangement and phraseology of his article, believing that in this way the individuality of each would best be preserved. The introduction is of unusual interest as the last printed words of the late Prof. Wm. Goodell, and he has assumed unconsciously the reminiscent and prophetic vein. We can give our readers no better idea of his style on this occasion than by quoting his own words:

"One advantage accruing to the writer of an introductory lies in the circumstance that he is not limited to any given text or narrowed down to a special topic. Untethered to thesis or theme, he can range at large over the whole field of the subject-matter and treat it pretty much as he pleases. Now as Mentor he can preach his homily; now as pupil he can con his hornbook.

"In this survey of gynecology I shall not hesitate to bor-

row from my previous writings on the subject, without credit and without stint. I shall also use the pronoun of the first person, not from egotism, but in order to invest my own views with that personality which the editor has urged all his collaborators to assume. Nor, on occasions, shall I hesitate to show myself a proselyte of the gate—one who does not wholly yield up his creed to all the articles of orthodox medical belief, or subscribe to all the obligations of its ritual.

"With the ancients the Golden Age was in the past. With us it looms as the promise of the future; and indeed a great future lies before us. At the brink of the twentieth century let us look back upon the one that is fading away, and a truly wonderful one it has been."

And then the writer follows with a hasty but comprehensive review of the gynecology of the century now drawing to a close. We think him too sweeping when he asserts that the scientific treatment of appendicitis, of perityphlitis and of all intestinal and visceral lesions have come from the advances in gynecology. The truth is that modern abdominal surgery including gynecology proper, has come as a result of the immortal discoveries of Pasteur and the consequent technique of Lister. The writer of this remarkable introduction makes one of the most powerful appeals for the preservation of the ovaries, and as a citizen and patriot not less than a physician, he inveighs against the custom of the time by which the propagation of children has almost urges conservatism in the use of the knife (see page 20) for ailments very frequently having their origin in the nervous system rather than in the reproductive organs.

"Nerve-strain," says our author, "or nerve-exhaustion comes largely from the frets, the griefs, the jealousies, the worries, the bustles, the cares and cares of life. Yet strangely enough, the most common symptoms of this form of nerve disorder in women are the very ones which lay tradition and dogmatic empiricism attribute to ailments of the womb." (Horace summed up these worries in the phrase, *res angustæ domui*.)

The other chapters in the book are written from a clinical standpoint, and are the views of men of great experience as will be seen from the list above given. The work is systematic and we feel sure that it is as a whole the equal of any similar book, and in many respects it is immensely superior to any gynecology recently issued. The surgery of the rectum and anus, and of the breast is given respectively by Dr. Montgomery and Dr. Allen.

**Surgical Pathology and Therapeutics.** By JOHN COLLINS WARREN, M.D., Professor of Surgery in Harvard University; Surgeon to the Massachusetts General Hospital. Illustrated. Cl., pp. 832. Philadelphia: W. B. Saunders. 1895. Price \$6.

Instead of dedicating this book to anybody, Professor Warren has the following motto from the Georgics of Virgil:

*"Felix qui potuit rerum cognoscere causas  
Atque metus omnes et inexorabile fatum,  
Subiecit pedibus strepitumque Acherontis arari."*

Which Dryden has freely translated:

*"Happy the man who studying Nature's laws  
Through known effects can trace the secret cause,  
His mind possessing in a quiet state  
Fearless of Fortune and resigned to Fate."*

The book is divided into thirty-two chapters beside the appendix as follows: I, Bacteriology; II, Surgical Bacteriology; III, Hyperemia; IV, V, Simple Inflammation; VI, VII, VIII, Infective Inflammation; IX, The Process of Repair; X, Gangrene; XI, Shock; XII, Fever; XIII, Surgical Fever; XIV, Septicemia; XV, Pyemia; XVI, Erysipelas; XVII, Hospital Gangrene; XVIII, Tetanus; XIX, Hydrophobia; XX, Actinomycosis; XXI, Asthma; XXII, Glanders; XXIII, Snakebite; XXIV, Tuberculosis; XXV, Surgical Tuberculosis of Joints; XXVI, Tuberculosis of the Soft Parts; XXVII, Diseases of Bone; XXVIII, Tumors; XXIX, Carcinoma; XXX, Sarcoma; XXXI, Benign Tumors; XXXII, Aseptic and Antiseptic Surgery.

The appendix contains articles on the blood serum therapy in rabies; tetanus; treatment of cancer; methods of pre-

paring erysipelas toxin; examination of tumors; staining methods—tumors; so-called parasites of cancer; decalcification of bone. There are 132 illustrations in the text and 4 full page plates.

It is thus seen that the scope of the book is limited strictly to the subjects included in its title. It therefore can not take the place of the more elaborate works on pathology or bacteriology, nor does it assume to do so. The teaching is quite in accord with modern advanced views, but if the author has a leaning it is always in the direction of conservatism. He is always guarded and makes positive assertions only where the proof is undoubted, and usually produced.

In regard to the *Lustgarten bacillus* he says:

"The question of the microbic origin of syphilis has been extensively discussed and investigated, but as yet no definite conclusions have been reached which are generally accepted by bacteriologists."

In regard to the cause of inflammation our author, as we think properly, denies the extreme view of Heuter that all inflammations are due to bacteria, and he recognizes mechanical violence, and chemic action including heat and cold, as agents in the production of certain inflammations.

While usually quite clear there are occasional obscurities, thus on page 162 the author says: "Nearer the central point of the inflammatory process the cut surface has a pork-like aspect." We confess with due humility that we do not know what a "pork-like aspect" is. The chapter on the process of repair is admirably written both as to matter and form. We think, however, the writer is in error where he attributes the priority in the application of the double ligature in tying the larger vessels, to Senn and Ballance and Edmunds, for Prof. Moses Gunn long ago taught that method, and in 1870 formally proposed the "constricting silver ligature" as a substitute for ordinary ligation in innominate aneurysm. The purpose in the case mentioned was not the same as that mentioned by our author on page 254, but the principle was clearly enunciated of occluding the vessel by approximation of its walls without rupture.

The chapters on tumors are excellent and interesting. In regard to the Coley treatment of inoperable sarcomata the author says: "The experience of many prominent surgeons with this method of treatment has not been satisfactory. There is little doubt that it is of little if any value in the treatment of carcinoma. The fact that a considerable number of cases of sarcoma have been benefited by this treatment, and that a few have been cured renders it desirable to experiment further in this direction."

To aid in the correction of the next edition, we note a few errors of proof reading, among them "Kelbs" instead of Klebs, page 67, and "Recklighausen," page 87. These are scarcely worthy of notice as they are such as might occur in any work. It might seem a little perfunctory to devote so much space as is here given to the subject of hospital gangrene, a disease that in the present day has only a historical interest, but as it might possibly "come again some day" when the germicides are away, perhaps the chapter is not altogether in vain.

We congratulate the author on the production of an admirable book, alike creditable to himself and to American surgery, and we venture to predict its entire success. The field was ready, and this work will well occupy it, until a more recent favorite shall appear upon the scene.

#### Fourteenth Annual Report of State Board of Health of New York.

This report, which is for the year 1893, was transmitted to the Assembly by the Governor February, 1894. It consists of two volumes of 869 and 510 pages respectively and a volume of maps. The report gives in detail a statement of the work performed and of all expenses connected therewith. The Board invites attention to the annually increasing amount of work done. The report justly gives credit to the work of the U. S. Marine-Hospital Service. It says:

"Owing to active and efficient work on the part of government inspectors abroad and at ports of embarkation, cholera, which broke out in Western Europe in the spring with renewed vigor, did not gain a foothold in this country."

The Board, however, were not idle, for the threatened invasion caused greater activity on the part of all employed in the health service of the State. Great advancement of hygiene throughout has resulted not only in the prevention of a threatened epidemic, but in the public education and better appreciation of sanitary science, and its practical application. One of the most important duties of the Board consists in the examination and approval of submitted plans for systems of sewers, sewage disposal and water supply of villages, towns and cities throughout the State, and a great portion of the report is properly taken up with a detailed statement of these examinations. The vital importance to the public of the water supply, and of sewage disposal, has created the need for such work by a properly constituted board, and it is impossible to place an estimate on the value of such service. The New York Board is doing excellent work and the report well illustrates it.

## PUBLIC HEALTH.

**Smallpox in Iowa in 1894.**—Dr. J. T. Kennedy, Secretary of the Iowa State Board of Health, in reviewing the health of that State during 1894, says that more than twice the number of cases of smallpox occurred than ever before in the history of the State, in any one year, and the casualties therefrom have been greater. Chicago has been a constant menace, and has furnished nearly all the initial cases. The disease appeared at over twenty different points, and the aggregate number of cases has been over one hundred. At scarcely any point, however, did the disease get beyond the family originally attacked, and at only two points, New Hampton and Pacific Junction, was there any considerable number attacked. Dr. Kennedy compliments the local health boards for their prompt compliance with the rules and regulations of the State Board, whereby the disease was "remarkably well handled" respecting quarantine, disinfection and vaccination.

**Physical Training of Youth.**—A writer in the current number of the *Atlantic Monthly*, after analyzing the various systems of physical training in vogue in the public schools of a number of American cities, comes to the conclusion that no one of them is exactly suited to the requirements of American youth—that the aims of mere muscular development and military action and bearing dictate to a harmful extent the character of the exercises which obtain favor in our schools; and adds: "It is not too much to expect that the character of our physical training will shape in a certain measure the destiny of our nation, for history is emphatic in proving this of other times and peoples; and so it behooves us calmly to examine our ideals, and see if the highest that can be kept in view, considering our peculiar needs, are not those of self-poise and deliberation, and the grace and strength of mind and body which flow from them."

**Booming the Crematory.**—*Florida Health Notes* begins, in the January, 1895, number, a collection of original contributions and extracts "bearing on the discussion and growing practice of this disposition of the dead"—to wit, cremation. It learns that the crematory in San Francisco is so crowded with business that it has to refuse three out of ten offerings made; and a sanitary conference, composed of more than one hundred physicians from all parts of the State, recently passed a resolution declaring emphatically in favor of cremation and urging that it should become the national method of disposing of the dead. In Boston the records of the Massachusetts Cremation Society, whose crematory is near the Forest Hills Cemetery, show that up to June 1, 1894,—that is, five months after the opening of the crematory—there

were forty incinerations, the number constantly increasing each month. In May there were sixteen in all. "Socially considered, all classes of people have been represented in this new mode of disposing of the dead here, and all ages—from 94 to 5 years—figure in the official entries of cremation. The system is a perfect success, and the average time required for the complete reduction of the body to ashes is about one and one-half hours."

**Antitoxin Production.**—The New York City Board of Health is increasing its antitoxin "plant." A new laboratory, to cost \$5,000, is being fitted up at the Willard Parker Hospital, at the foot of East Sixteenth Street and will be in readiness in a short time.

**Asiatic Cholera.**—A cable dispatch of the 2d inst. reports that cholera has broken out at Pera, a suburb of Constantinople. The disease is practically at an end in the Argentine Confederacy, where the most vigorous measures were resorted to—even to burning infected houses with their contents.

**An Epidemic Predicted.**—Colonel Maurice calls attention in the *United Service Magazine* to the Chinese claim that there are 500,000 men massed around Pekin. This force has already been there for some time, and it is likely to remain for several months longer. It is an elementary maxim of military tactics that a large force of men should not be gathered until a short time before they are to be employed; otherwise an epidemic, resulting from enforced lack of sanitary arrangements, is almost inevitable. Therefore, the writer predicts that as soon as warm weather begins in the spring there will be a most frightful outbreak of pestilence in some form or other, probably in many forms, but beginning with malignant typhus in its most virulent shape. Colonel Maurice suggests that while there is yet time all foreigners in Pekin be withdrawn under adequate protection.

**Smallpox.**—During the first thirty-six days of 1895—January 1 to February 5 inclusive—there were 222 new cases of smallpox reported in Chicago, a daily average of 6.3. During January the daily average was 6.5; during the first five days of February the average had fallen to 5.2 per day, but the mortality had increased from 17.6 per cent. for the aggregate, to 23.8 per cent. for February; this increase is attributed to the unusual severity of the weather since the first of the month. Remaining under treatment, midnight February 5, in hospital, 116. Reports of the disease in Detroit are conflicting; Health Officer McLeod reported twenty-eight cases under treatment at the close of the month—eighteen in hospital, ten in homes. From unofficial sources it is learned that Surgeon Hutton, M.-H. S., to whom had been tendered the position of Health Officer, has declined the appointment. Secretary Wingate, of the Wisconsin State Board of Health reports, February 4, five new cases and three deaths in Milwaukee during the week ended February 2; total under treatment, forty-three; in hospitals, fourteen; in homes, twenty-nine. There were also six new cases during the week in Greenfield, Milwaukee County.

**Quinin in Palustral Fevers.**—At a recent meeting of the Paris Therapeutical Society M. Bardet stated that, until lately, quinin salts were administered to travelers who intended visiting tropical or malarious countries. But at a recent meeting of the Paris Therapeutical Society (reported in *Gaz. Med. de Paris*) M. Bardet stated that the number of diseases in which these salts are applicable is diminishing, especially since Ross (India), Miranda-Azevedo (Brazil) and Treille (Algeria) have shown that the tropical bilious fevers are more to be feared than the paludal fevers. These attack especially Europeans living in hot countries whose hygiene is defective and who are given to alcoholic excess. The hygiene of armies sent to these countries should be carefully supervised and the supply of alcoholic drinks interdicted. This gives better results than the prophylactic use of quinin; the latter should be reserved for cases when it is

indispensable, as for example, during prolonged stay in low marshy regions. It is necessary to keep in mind the irritating effect of quinin on the digestive tube, which weakens the individual and also renders him insensible to the quinin salts. Ferrand observed that the use of quinin is attended with many inconveniences. For preventive purposes he thought quinquina was preferable.

**Artificial Foods and Infant Mortality.**—Statistics from the lists of registered deaths in England compiled by Dr. Hugh R. Jones (*Brit. Med. Jour.*) show that 42 per cent. of infant deaths may be referred to digestive disorders. Infant mortality in Norway and Sweden, where almost every child is nursed by its own mother, is but 10 per cent. In Wurtemberg the mortality of breast-fed children is 13.5 per cent., of artificially fed children, 42.7 per cent. In Munich, respectively 15 and 85 per cent. In lower Bavaria, where maternal nursing is the exception, the mortality is 50 per cent. Dr. Hope, Medical Officer of Health of Liverpool, investigated the methods of feeding in 718 fatal cases of diarrhea in children. Of these but 30 were breast fed; 391 were reared wholly on artificial food, while 297 were partly nursed and partly fed on artificial food. Those wholly nursed fare the best, and those partly nursed are better off than those wholly fed on artificial foods. It is clear that maternal nursing should be encouraged, and early weaning and the substitution of artificial foods for the breast-milk should be discouraged; but the tendency is the opposite in all classes of society—a tendency which is increased by the increasing employment of women in industrial and commercial occupations.

**Intermittent Water Filtration.**—In his report to the Massachusetts State Board of Health on water filtration, Mr. G. W. Fuller compares the manner of operating filters in Europe and in this country, to the advantage of the latter. In Europe the filters are operated with the surface of the sand continuously covered with water, while in this country the intermittent method of operation is usually followed, in which from time to time the water is shut off from the surface for a certain period, the beds drained dry, and the pores between the grains of sand become filled with air. The advantage of the intermittent action is that it provides within the filtering material an additional amount of oxygen with which the bacteria may perform their functions, while the advantage of the continuous action is that, when it is selected, the area of the filter beds need not be so great as for intermittent action. From his experimental filtration of the Merrimac River water at Lawrence, Mass., however, the fact appears that there is no marked difference in the average results obtainable by the two methods, the explanation being that a practically sufficient quantity of free oxygen is held in the water as it flows to the filters; oxygen has never been absent in any of the samples of the effluent from the continuously operated tanks, long series of analyses of the effluents being made from both continuous and intermittent filters.

**Cheaper Sulphur.**—Sanitarians who believe in the bactericidal properties of  $\text{SO}_2$ , and followers of that school of medicine whose "third great doctrine" is the psoric origin of at least seven-eighths of all chronic diseases, will rejoice to learn that the great Louisiana sulphur deposit—variously valued at from \$30,000,000 to \$100,000,000—has finally been made available. This vast mass lies some hundreds of feet below the surface in Calcasieu parish and is overlaid by an immense quicksand, to get through which hundreds of thousands of dollars have been spent and several companies bankrupted without ever getting sulphur enough to make a brimstone match. The last fruitless attempt was that of a Belgian engineer who endeavored to conquer the quicksand by freezing it solid and boring it through, erecting valuable refrigerating machinery for that purpose; but the quicksand would not stay frozen, and that system of mining had to be abandoned. Recently the Standard Oil Company got control of the property and set about mining in a fashion the very opposite to that of the Belgian engineer. Instead of using freezing as the means of getting at the sulphur, it is trying heat. Superheated water is forced

through a ten-inch pipe, on the sulphur, melting it, and the liquid sulphur water is then pumped up. Exposure to the air, so as to evaporate the water, leaves almost pure sulphur. A New York *Sun* dispatch says the experiment has been a success beyond expectations. It was tried for the first time only a few days ago, and several tons of sulphur obtained at the first strike. It has been operated successfully ever since.

**Antitoxin Treatment of Diphtheria.**—The JOURNAL is indebted to Dr. C. O. Probst, Secretary of the Ohio State Board of Health, for the report of Dr. W. T. Howard, Jr., of the Pathologic Laboratory of the Western Reserve University at Cleveland, concerning the antitoxin treatment of diphtheria at Ashtabula—"the largest series of cases yet treated with the antitoxin in America," so far as the Secretary is aware.

In all, eighty-two cultures were made by Dr. Howard, to-wit: twenty-nine times in convalescent cases to determine whether or not it was necessary to continue quarantine; in twenty-eight instances for diagnosis; and in twenty-five cases treated with antitoxin. In some of the quarantine cases reported, examinations showed the presence of diphtheria bacilli for many days after the disappearance of the false membrane. In these cases the quarantine was not raised until the throat was proved to be free from diphtheria bacilli, a very much safer procedure than the ordinary time limit usually followed. From the results it appears that the diphtheria bacilli disappear from the throat in a shorter time in cases treated with the antitoxin than in cases treated by the ordinary methods.

The twenty-eight cases treated by Drs. Alrich, Dickson, Dorman, Flower, Gilchrist, Morse and Pardee, between Dec. 17, 1894, and Jan. 5, 1895, were divided into four classes, as follows: Mild five, of medium severity ten, severe seven, malignant six. In every case in which the remedy was used benefit was noted. In all but one case the improvement was marked. In mild cases and in cases of medium severity the affected part cleared up rapidly, decided improvement being noted within twenty-four hours. The dosage varied with the severity of the case. The mild cases received from 12 to 20 c.c. of the remedy in all. The amount given in cases of medium severity varied from 35 to 55 c.c. Cases classed as severe received from 28 to 79 c.c. One of the malignant cases received 113 c.c. in five days. The usual initial dose was the contents of one of the phials (22 to 25 c.c.). The further treatment of the case was governed by the severity of the symptoms and the patient's apparent needs. Where it seemed necessary another dose was given within a few hours, but usually the second dose was not given until after twenty-four hours.

Characteristic changes following the injections were fall in the temperature, slowing and strengthening of the pulse with, in some cases, a rise in the arterial tension. Changes in the appearances of the false membrane were marked. Within twenty-four hours it would lose the characteristic dry, dull, and opaque appearance and grayish color, and become pale white or gray in color and moist and somewhat translucent in appearance. Frequently in this time it would loosen and curl up at the edges. In a variable time, from twenty-four hours to several days, the false membrane would separate, often in large masses. The mucous membrane could then be seen to be more healthy in appearance than in cases not treated with antitoxin. Drs. Flower and Dickson lay especial stress upon this point and note the fact in the reports of their cases. After the use of the remedy, often within twenty-four hours, patients were markedly brighter in appearance.

Of the twenty-eight cases treated, three died, a mortality of 10.7 per cent. The three fatal cases are of particular interest:

The first, N. F., a boy of 6 years, had been ill with diphtheria six days before the treatment was instituted. Two weeks previous to this he had had measles, complicated by bronchitis. When first seen there was a thick false membrane on both tonsils, on the pharynx, extending over the roof of the mouth, and in both nares. He was hoarse and could not

speak above a whisper; the larynx was evidently involved. The cervical glands were very much swollen. Temperature, 103; pulse, 150, weak; respiration, 30. The prostration was great and the case was looked upon as entirely hopeless. He reacted somewhat to the antitoxin and lived two days after the first injection. Before death, although he was intubated, the respirations were 70 per minute and he evidently had pneumonia. Cultures made from the throat showed diphtheria bacilli and large numbers of the staphylococcus aureus. Clinically and bacteriologically this was a case of severe mixed infection.

The second fatal case is of equal interest. N. C., female, 27 years old, ill six days before antitoxin was administered. She was seen by Dr. Dickson with her physician, Dr. Flower, on the third day. They both thought the case hopeless then. At the time of the first injection of antitoxin, there was a thick grayish-yellow false membrane over the tonsils, pharynx and roof of the mouth. She was hoarse, could not speak above a whisper and complained of pain in the larynx and trachea. The cervical glands were markedly swollen. The pulse was weak, 140 per minute. The face and lips were cyanotic. She had not been able to swallow food for twenty-four hours. Under continued large doses (113 c.c. in all) of antitoxin she showed decided improvement. The false membrane cleared off entirely and the throat was clean by the afternoon of the fifth day after the first dose of antitoxin. That morning her pulse was stronger and better than any time during her illness and it was thought that her chances for recovery were good. That afternoon, suddenly, she became pulseless at the wrist and died in a short time of acute dilatation of the heart. As far as the study of the good effects following the administration of antitoxin is concerned, this was the most interesting case presented for observation. She invariably showed marked improvement after each injection of the remedy and the false membrane disappeared in the most satisfactory manner. She had no local treatment after the antitoxin injections were instituted, except an occasional gargle of a solution of Sailer's tablets. The diphtheria bacillus was found in pure culture in the false membrane.

The third fatal case was that of a baby 4 months old, ill with diphtheria four days before antitoxin injections were given. The rectal temperature was 105; the pulse 120 to 160; the respirations accelerated. A false membrane covered the tonsils, uvula and pharynx. Antitoxin was administered on the fourth day of the disease and was followed by a marked improvement; the throat being clear of false membrane on the third day. The child died, however, on the evening of this day. Cultures which were made just before the antitoxin was given showed the diphtheria bacillus and large numbers of the staphylococcus aureus. The child probably recovered from diphtheria and died of septicemia.

In all of the fatal cases the antitoxin treatment was instituted late in the disease. "In the first two of the fatal cases there was involvement of the larynx and the first and last cases were severe types of mixed infection." The first two were said to be the most malignant of the epidemic and on account of their severity were the first cases to receive the antitoxin. The best and surest results were obtained when the antitoxin was administered within the first forty-eight hours of the disease, though there were several malignant cases which showed rapid improvement and recovered when the treatment was not instituted until the sixth day of the disease.

These experiences have in the main confirmed those of other observers in regard to the efficiency of the antitoxin treatment of diphtheria. They tend to emphasize the experience of most of those who have used it—that the earlier the treatment is instituted the better the results and the smaller the doses necessary, and the additional facts that in cases not treated until late in the disease (third to sixth day or later) and in cases of mixed infection, the best results can not be expected.

Study of the cases of diphtheria in Ashtabula and at the Harbor (where diphtheria was endemic) reported to the Health Department from Jan. 1, 1894, to December, 1894, just before the present epidemic started, shows 114 cases with 19 deaths, a mortality of 16.6 per cent. From Dec. 6, 1894, to January 1, 1895 there were reported eighty-two cases of diphtheria with twenty deaths, a mortality of 24.4 per cent.

In this, as in most epidemics, it is probable that the most severe cases were among the first and that the most susceptible individuals were attacked earliest, but after due allowances have been made for these factors the antitoxin treatment has been followed by a most gratifying lowering of the mortality.

As soon as the supply of antitoxin warranted it, an attempt was made to immunize all individuals in infected houses as far as possible. For a variety of reasons this plan could not be applied to every household. Altogether twenty-five persons were given antitoxin for immunization; of these seven contracted diphtheria, but nearly all had mild attacks. It is not improbable that several of these were already infected at the time of the injection. The amount used varied with the age and body weight, from 1 to 4 c. c. being given. In several cases this was followed by erythema and urticaria. In one case the victim in a few minutes was seized with a violent paroxysm of sneezing, which was shortly succeeded by an attack of asthma. Some hours later this was followed by a troublesome urticaria. But as a rule no discomfort followed the administration of the remedy whether it was used for treatment or for immunization.

With patients receiving the antitoxin, little or no local treatment was used. In cases which were not brought under the antitoxin treatment until late in the disease (third to the sixth day) sprays of hydrogen peroxid or of mercuric chlorid when used were always stopped. As routine treatment in connection with the antitoxin, as cleansing agents and for the mechanical effects, patients were made to use a mild gargle of boric acid solution or a solution of Seiler's tablets, both of which may be regarded as harmless. In some cases, however, even this was omitted. The patients were encouraged to eat, and when their condition called for it, were freely stimulated; for this alcohol and strychnin were chiefly relied upon.

## ASSOCIATION NEWS.

**The Section of Neurology and Medical Jurisprudence** have arranged the following symposiums for the May meeting at Baltimore: Epilepsy, Medically, Surgically, and Therapeutically considered; Hypnotism, and Mental Therapeutics, and its Medico-Legal Relations; Electricity, some new Therapeutic Relations and Questions of Treatment. Short practical papers on these topics are urgently solicited. Other papers on subjects belonging to this Section will be welcomed.

## SOCIETY NEWS.

**The Bussey District Medical Society** held a regular meeting at Tracey, Iowa, January 31.

**The Iowa State Medical Society** will hold its forty-fourth annual meeting at Creston, April 17-19.

**The Capital District (Ill.) Medical Society**, at its annual meeting in Springfield elected the following officers: President, Dr. E. J. Brown, Decatur; Secretary, Dr. B. M. Griffith, Springfield; Treasurer, Dr. R. C. Matheny, Springfield.

**Ramsey County (Minn.) Medical Society.**—The thirty-first annual meeting of this society was held January 28. The following officers were elected for the ensuing year: President, Dr. C. E. Riggs; Vice-President, Dr. Willis E. Hallowell; Secretary, Dr. Charles R. Ball; Treasurer, Dr. A. A. Pine.

**The Rome County (N. Y.) Medical Society** perfected its organization January 30, by the election of the following officers: President, Dr. C. C. Reid; First Vice-President, Dr. T. M. Flandrau; Second Vice-President, Dr. E. J. Lawton; Secretary, Dr. Calvin B. West; Treasurer, Dr. James Middleditch.

**The Medical Society of Southwestern Iowa** was organized at Creston, Iowa, January 30. The following officers were elected: President, Dr. B. W. Torrey, Creston; Vice-Presidents, Drs. Cokenower, of Clarinda; E. Potter, of Corning; Stanton, of Chariton; Bosbyshell, of Glenwood; Mulhern, of Greenfield. Treasurer, Dr. Paschal, of Bedford; Secretary, Dr. F. E. Sampson, of Creston. The next meeting will be held in Creston February 21.

## NECROLOGY.

V. W. May, M.D., of Lawrence, Kan., February 4.—William Wallace Cook, M.D., of Woodstock, Ill., February 4, aged 39.—Jamin Strong, M.D., of Cleveland, Ohio, January 28, aged 69.—F. W. Ostrander, M.D., of Brooklyn, N. Y., January 29, aged 90.—Dr. Brandt, of Warrenton, Mo., January 15.—A. T. Stephenson, M.D., of Harrodsburg, Ky., January 12.—Heinrich Harpke, M.D., of Milwaukee, January 12, aged 68.—Miles R. Bohannon, M.D., of Lynchburg, Va., January 19, aged 69.—W. A. McCulley, M.D., of Independence, Kan., January 22.—Cyrus Haven, M.D., of Hannibal, N. Y., January 25.—Wm. M. Fee, M.D., of Melbourne, Fla., January 27, aged 73.—Dr. Stover, Wayland, Mo., February 4.—Francis J. Hammond, M.D., Indianapolis, February 1.—Horace Gaylord, M.D., Pontiac, Ill., January 30.

## MISCELLANY.

**The Philadelphia Medical Club** held its annual meeting January 30. The following officers were elected for the ensuing year: President, Dr. Hobart A. Hare; First Vice-President, Dr. Henry Beates; Second Vice-President, Dr. A. K. Minich; Secretary, Lemuel J. Deal.

**Monument to Charcot.**—The committee appointed to collect funds for the purpose of erecting a monument to Charcot, of which Professor Brouardel is the President, has collected 30,000 francs and as soon as the funds from foreign countries have been turned over, the lists will be closed.

**Von Helmholtz' Library.**—The German Emperor has ordered his Chancellor, Prince Hohenlohe, to purchase the library of the late Prof. Hermann von Helmholtz for the Imperial Institutes of Physics in Berlin. The library is supposed to be the best private collection of works of their class in the empire.

**Jugulation of Pneumonia.**—Petresco, of Bucharest, claims to have successfully jugulated pneumonia by enormous doses of digitalis. In 1891 he had treated 825 cases, with a mortality of 2.06 per cent., and in 1893 he claimed to have treated successfully 1,061 cases during the previous twelve years. (*Rev. de Med.*) He gives one to three drachms daily of digitalis leaf in infusion (5i to 3viifs), a tablespoonful being given every half hour.

**Diagnosis and Treatment of Diphtheritic Angina.**—In twenty-eight cases of angina with false membrane, and suspected diphtheria, only eight had the Löffler bacillus, seven had streptococci, five had staphylococci, eight had different microbes, coli bacilli, pneumococci, etc.; of these eight cases, two died. Catrin has practiced in all cases repeated touching every two or four hours with a solution of potassium permanganate (1 to 100). This solution is neither caustic nor painful.—*Revue des Science Medicales*, Jan. 15, 1895.

**Treatment of Acute Articular Rheumatism by Malakin.**—In a trial made on four rheumatics, Montagnon found that malakin was never harmful even in great doses; that it augmented the quantity of urine; facilitated the elimination of uric acid, and distinctly lowered the temperature; never produced ringing in the ears, or digestive troubles. The ordinary dose is 6 grams in twenty-four hours. It may be carried to 10 grams without danger, in divided doses.—*Revue des Science Medicales*, Jan. 15, 1895.

Cerna, "Notes on the Newer Remedies," 1895, states that malakin (a substance closely related to phenacetin) is best given in wafers or capsules; the single dose is 0.5 to 1 gram, and "for children it can be administered in some kind of fruit jelly, in corresponding doses."

**Washington State Board of Health.**—The Washington State Board of Health and Bureau of Vital Statistics held its regular annual meeting at Olympia, January 21. Dr. J. B. Eagle-

son, of Seattle, was elected President, and Dr. G. S. Armstrong, of Olympia, was re-elected Secretary. The other members of the Board are Dr. N. Fred Essig, of Spokane, Dr. John T. Lee, of Tacoma, and Dr. E. E. Hegg, of North Yakima. The Board decided to establish a laboratory for bacteriologic and experimental work, and appointed Dr. A. B. Kibbe, of Seattle, Director and Bacteriologist.

#### **Society for the Relief of Widows and Orphans of Medical Men.**

—The Society for the Relief of Widows and Orphans of Medical Men of New Jersey was incorporated in 1882 and has continued to grow both in influence and membership. Since its organization, 241 physicians of the State have become members; of which number 22 have died, 28 been dropped for various reasons, leaving at the present time 191 active members. The Permanent Fund amounts to \$1,338.42, and it is intended eventually to allow small annuities to widows and minor children in cases of need. The amount already paid to the families of deceased members amounts to \$2,478. The total cost of running the society during the past year was \$19.67.

**Syphilitic Gangrene of the Tongue.**—At a meeting of the Paris Society of Dermatology, reported in the *Gazette Medicale de Paris*, M. Mendel presented a man aged 55, with gangrene of the tongue very probably of syphilitic origin. The patient presented himself at the Hospital Saint Louis with his tongue enormously swollen and the anterior third, green and pulpy. Two days later this greenish part sloughed off in the form of fetid detritus, and the remainder showed a separated surface already undergoing repair. Two or three similar cases have occurred in carcinoma of the tongue, but it seems probable that in this case we have to deal with syphilis, in the form, possibly, of an unusually large phagedenic gumma. The patient had syphilis in 1882 and has been very poorly taken care of. The characteristic signs of cancer are lacking—cachexia, glandular enlargement, otalgia and spontaneous pains, fetidity and loss of blood.

**Suicide of Physicians.**—Dr. J. U. Hall, one of the editors of the *Colorado Climatologist*, offers as the causes of the increase of suicide among physicians, first, the proneness of medical men to resort to artificial stimuli when overworked; and, second, the overcrowding of the profession whereby the struggle for existence is made so bitter that many conclude that life is not worth living. In his own State, as member of the Colorado Medical Licensing Board, Dr. Hall has helped to license 2,066 physicians since 1881. The total population of Colorado by the last census amounted to only 442,000. Thus they have in fourteen years licensed one physician for every 213 inhabitants. Dr. Hall adds: "It is needless to say that a large part of these have moved on, and are now trying to find a still easier place. If all had remained, we should have died for lack of sufficient oxygen to support us"—an alternative less objectionable only than suicide itself and no less deadly.

**Argon—the New Element.**—At the recent meeting of the Royal Institution in London, on the 31st ult., it is claimed that the existence of the new element, discovered by Lord Rayleigh and Professor Ramsey and to which they have given the name *argon*, was fully demonstrated.\* It is said that the discoverers have finally succeeded in separating it from the atmosphere on a large scale and have sent a portion to Professor Crookes and a portion to Dr. Olszewski of the University of Cracow, to liquefy and solidify, and that these physicists have found that the new substance gives a spectrum of its own and has its own boiling point, freezing point, critical temperature and critical pressure, all different from those of any other element. The cable dispatch says: "Argon gives two spectra, the red and blue, and it is this which raises a doubt whether the investigators are dealing

with one or two substances. If the latter should prove true then there is a new vista opened up, and it is suggested perhaps one of these substances will prove to be Professor Crookes' ideal protyle, the ultimate basis of matter of which all others are only combinations."

**Treatment of Syphilis by Mercurial Injections.**—Lendin has observed in 106 subjects the comparative action of subcutaneous injections of 1, calomel; 2, salicylate of mercury; and 3, mercuric thymol. Forty-three patients were treated with injections of calomel in doses of, gr. 0.05 to gr. 0.2 (in all 186 injections—100 double and 86 single). Of these forty-three patients, thirty-four were treated with calomel from the beginning; the other nine had been given other medicaments as well. The injections of mercuric thymol (83) and of salicylate of mercury (852) were made in sixty-four subjects, in doses of from gr. 0.05 to gr. 0.1, in the region of the great trochanter. These were poorly borne and were replaced by mercury internally and by inunctions. The reaction caused by the calomel injections was always more pronounced than that following the other salts. Suspension in glycerin produced an abscess in 24.5 per cent. of all cases, while suspension in oil produced only 9.7 per cent.; moreover, large and very painful swellings were produced which greatly annoyed the patients. Injections of the thymol and salicylate, on the contrary, in most of the cases were not followed by any inflammatory reaction, or if any appeared it was very slight; with no abscesses and an elevation of temperature in only fifteen cases. The author concludes (*Jour. de Med. de Paris*) that calomel occupies the first place in cases treated for the first time, by reason of its rapid therapeutic action; in cases of relapse, on the contrary, there is no appreciable difference between these three salts of mercury.

**Liability for Personal Injuries is not Changed by Presence of Microbes.**—A novel application of an old rule of law has been made by the United States Circuit Court of Appeals in the case of the Crane Elevator Co. v. Lippert, decided Oct. 1, 1894. This was an action brought to recover damages for personal injuries. The party who instituted it testified that he fell, and struck his shoulder upon some iron. He got up and walked home. He felt some pain in his arm, below the shoulder. It was swollen the next day, but he returned to work, and after working about an hour he went home and went to bed. About four days after, a doctor was called. His arm was then badly swollen. After treatment by two or three different physicians, he went to the hospital, where he was in bed about a month and was operated on by a surgeon, by whom a piece of diseased bone was taken out of his arm. The medical testimony tended to show that, when admitted to the hospital, he was suffering from tubercular osteomyelitis, resulting from the presence of microbes or tuberculous germs in his system; that, if these microbes or germs had not been present in his system, the fall and consequent bruise would not have resulted in the serious injury from which he suffered. The point was, therefore, made by the lawyers that the injury sustained was not the proximate result of the fall, but arose from the presence of tuberculous germs in his system. The court, however, holds otherwise. It says that the wrongful act of the party sued subjected the injured party to other and dependent causes, which were set in motion by the original hurt. It was the hurt occasioned by the fall which afforded an opportunity for the active development of the poisonous germs which had theretofore been innocuous. For this it was answerable. It was the wrongful act which gave rise to the subsequent injury, and it was not apparent that the injury would have occurred in the absence of such cause. The principle applicable is that when there is no intermediate efficient cause, the original wrong must be considered as reaching to the effect, and proximate to it.

**The Bubonic Plague at Hong Kong**, by Yersin, (*Bulletin Méd.* Sept. 24, 1894) and (*Annales d'Institut Pasteur*, viii, 9.) "Note on the plague by Kitasato," (*Bull. Méd.* Sept. 23, 1894.) 1. The bubonic plague which has raged from the month of May last at Hong Kong presents itself with the symptoms and clinical characters of the ancient bubonic plague, which has been observed from time to time in the East. The micro-

### FUNCTIONAL SPINAL PARALYSIS.

Read at the Chicago Academy of Medicine, Jan. 11, 1895.

BY SANGER BROWN, M.D.

CHICAGO, ILL.

Notwithstanding the progress that has been made within the last decade regarding the physiology and anatomy of the spinal cord, as well as the pathology and the pathologic anatomy belonging to the diseases of this organ, much obscurity remains. Many of the diseases of the spinal cord are not rapidly fatal, so that an opportunity for post-mortem examination can not be had at a period when the symptoms would suggest most strongly the desirability of such an examination. An autopsy in many cases is only available after the symptoms have advanced to such a degree owing to the extensive organic changes which have taken place, that examination of the cord at this period is of very little value in discovering the minute pathologic changes which may have given rise to the earlier symptoms. Nothing remains, however, at present but for clinicians to go on carefully reporting irregular and anomalous cases in the hope that the data thus afforded may finally in some way help to elucidate the pathology. It is in accordance with this purpose that the following case is reported:

*Case 1.*—F. O., Norwegian, aged 35, stone cutter, married, was admitted to the Cook County Hospital June 29, 1893. Nothing important in the personal or family history except that he had syphilis fourteen years ago. Habits regular, and he had always enjoyed good health prior to the present illness, which began about two years previous to admission while working at his trade. He worked in all kinds of weather and not infrequently in wet clothing. The first symptoms consisted of a numbness in the fingers and toes which gradually extended upward toward the elbows and knees respectively. There was also at the same time gradually increasing weakness and ataxia which had become so great eighteen months after the onset as to seriously interfere with his work. He could not hold or handle his tools as before, and would sometimes unexpectedly and involuntarily drop them, owing in part to lowered sensation and in part to muscular weakness, and his gait became awkward and uncertain. He knows that sensibility to touch was considerably impaired, but he does not feel so positive regarding the sensibility to pain. He had no trouble at any time with the functions of the eyes, bladder or bowels. About one month before admission he had to give up work entirely and was only able to walk with assistance. From this time forward he grew quite rapidly worse until one month after admission, when he was wholly unable to support himself on his legs and continued so for about six weeks. Examination upon admission revealed impaired sensibility to touch, and pin pricks, especially from the knees downward and less so from the elbows downward, progressively more marked as the distal extremities were approached, but normal elsewhere. The knee jerks were entirely absent, abdominal and cremasteric reflexes were normal, but the condition of the plantar reflex is not noted. Vision and the pupillary reflexes entirely normal. While in the hospital the patient was well nourished, ate and slept well, and was in fact in good general health. Though the appearance of his legs and arms would not indicate

actual atrophy they were rather small, considering the occupation of the patient, and he volunteered the statement that his arms particularly had gradually grown smaller during the last few months in which he had continued to work. As already stated, after he had been in the hospital about ten weeks, the latter six of which he was unable to walk, under the treatment of potassium iodid in full doses strychnia, iron and faradism he began to improve both in regard to motion and sensation and left the hospital fourteen weeks after admission to it, well enough to accept employment in a boiler factory four weeks after his discharge, and three months later all his symptoms had entirely disappeared except that his knee jerks had not returned.

As to his condition at this time his own statement has to be taken. He is an intelligent man and says that he frequently repeated the tests he had often submitted to while in the hospital. Indeed, so complete was his recovery at this time that his work requiring him to swing a thirteen-pound sledge was easily performed, and he could run down a street car, for instance, as readily as ever. A few weeks later he obtained employment at his trade at which he worked steadily and remained entirely well for about six months, when two weeks prior to his present admission, Aug. 20, 1894, the former symptoms somewhat suddenly returned and developed within a few hours to such an extent that he was unable to go on with his work. It should have been stated before that in this attack, and after the symptoms in the previous attack were pretty well developed there was a sense of considerable stiffness in the calves of the legs. In this latter attack, neither the subjective nor objective disturbance was so marked as in the first attack. In one month after the onset he was again entirely unable to walk and in essentially the same condition as before. His inability to walk on this occasion was of three months' duration when he began gradually to gain sufficient power for this purpose, and while the sensory symptoms have improved, if anything more rapidly than before, the improvement in the motor symptoms has been much less rapid. The treatment has been practically the same.

Somewhere in the hospital records it is noted that the gait has the characteristic ataxia of tabes, and the diagnosis of locomotor ataxia is recorded, but while there were evidently distinct signs of ataxy, it may fairly be doubted if the gait was very similar to that so often observed in genuine tabes. Since the patient has been under my observation, though the gait has been quite unsteady and he has been obliged to walk with a cane, I have not thought it strongly suggestive of tabes. It should be added that he can not stand alone with his feet together and his eyes closed, and though the fact is not, I believe, stated in the history sheets, it is very probable that the condition existed when he was first admitted.

The accompanying diagram, prepared by Professor Schaefer, of London, accurately represents the present state of our knowledge regarding the physiologic anatomy of the spinal cord and brain as regards the functions of motion and sensation.

Considering this case in reference to this diagram, in connection with some of the best established facts in the pathology of the nervous system, I beg to make the following suggestions. The symptoms could be accounted for by assuming a functional inactivity of the peripheral nerves supplying the muscles and integument of the extremities. It should be remembered that these are mixed nerves

containing both motor and sensory filaments. It should further be remembered, that the process could not be regarded as being confined to the extremities of one or two particular nerve trunks, but to the peripheral endings of all the several nerve trunks supplying the skin and muscles of the hands and feet.

Recent researches have demonstrated that the main function of the nerve cell is nutrition, and it is therefore reasonable to infer that if the function of the nerve cells (3 and 6) be impaired that the nutrition of their respective fibrous processes (5 and 7) would suffer, and furthermore, that the parts of these processes first to suffer would be the parts most remote from the cell bodies. This hypothesis would

*a*, skin on the surface of the body; *17*, a sensory cell in the medulla oblongata; *b*, sensory cell in the cortex of the brain; *c*, motor cell in the cortex of the brain; *D*, cell in the cerebellum where muscular movements are co-ordinated; *3*, motor cell in the spinal cord; *m*, muscle. The course of a stimulus at "*a*" can readily be followed to the cortex of the brain and back again to the muscle, resulting in a muscular movement.

explain why the disturbance of motion and sensation should begin in the fingers and toes and gradually extend upward. It would also explain why the knee jerks were lost, because the lesion would involve the reflex arc. (*a*, 7, 8, 10, 3, 5, *m*.)

The character of the early motor and sensory symptoms together with their mode of onset, excepting their chronicity, is very similar to that usually observed in cases described as ascending paralysis or ascending myelitis, but the absence of all constitutional symptoms, of disturbance of the functions of the bowels and bladder, together with the fact that complete and somewhat prolonged recovery ensued, make it apparent that the process did not advance to actual inflammation.

As the patient is an intelligent man, one other statement might be made which to some extent supports the view that the function of the cell in the anterior horn of the cord was at least impaired, and that is, without being interrogated upon the point he volunteered the assertion that his legs and arms shrunk considerably. In fact, if the shrinking noted by the patient were a slight degree of genuine atrophy it would be another evidence of the functional impairment of the cells in the anterior horn.

So far as the patient could judge, his recovery was complete, as he himself frequently applied all the tests to which he had been subjected while in the hospital, and could discover no impairment of motion or sensation, and he was even able to stand perfectly well with his feet together and his eyes closed, but he could never succeed in developing a knee jerk. Hence it would have to be assumed, unless he were one of those individuals naturally without a knee jerk, the full and complete functions had not been restored.

Hitherto, when functional disease has been invoked to explain disturbance of motion and sensation, the process has usually been assumed to have its seat in the cortical cells of the cerebrum, and there seems no good reason to doubt that such an assumption is generally correct, but at the same time there appears to me to be no good reason to suppose that functional disturbance might not be confined to the cells in the spinal cord.

In this case a functional disease might be assumed to exist, confined to the cells of the cerebral cortex, which would account for all the symptoms excepting the loss of knee jerks which ought to be increased, or at least present in cortical disease, inasmuch as the inhibitory influence which the upper motor segment (*a*) in the diagram normally exercises over the lower motor segment (*3*) would be impaired, and furthermore, hysterical (cortical) quadriplegia with such an onset and with such sensory symptoms as the patient presented has not been described, so far as I can recollect. I wish to repeat, therefore, that to my mind the type, course and distribution of the symptoms vastly favor the hypothesis that the lesion was spinal.

It might be added that the absence of lightning pains, the rapidly progressive weakness and the complete recovery tell conclusively against a diagnosis of locomotor ataxy; while if myelitis had been assumed to exist and had advanced far enough to have given rise to such severe and persistent paralysis as happened in this case, some more marked indication of permanent injury to the elements of the cord and disturbance of the function of micturition together with increase of the knee jerks might be expected. Neuritis advancing to so high a degree of paralysis would have been accompanied by severe pain, tenderness of the nerve trunks and marked atrophy.

That the functional disturbance above described may indicate the approach of an organic process would seem to my mind not at all improbable.

#### DISCUSSION.

DR. HAROLD N. MOYER—The case as presented by Dr. Brown and his deductions from it are very instructive. If we stop for a moment to consider the pathology of the nervous system we are at once met with three periods. The first includes purely clinical demarkations with the terms locomotor ataxia, spastic spinal paralysis, etc. We then come to the period of pathologic anatomy, and it was but natural the pendu-

lum should swing rapidly in the other direction, and that the term, locomotor ataxia, should yield to the term, posterior spinal sclerosis, and the term, infantile paralysis to poliomyelitis anterior acuta, and other terms distinctive of definite and fixed pathologic changes. That period, I think, has already passed, and we are confronted to-day with certain questions which negative somewhat the strict anatomic distribution of nerve lesions as, for instance, we no longer regard locomotor ataxia or tabes as a pure sclerosis of the posterior columns of the cord, but we class it under the general diseases of the nervous system; and so with many other affections. The reason of this is perfectly apparent. The first and most palpable lesion associated with a given set of symptoms was supposed to be by a direct and positive accounting for that set of symptoms, and he did not take into account the secondary conditions, that may have been produced by the later stages of an exhausting malady; in other words, a mixed change due to marasmus and other depressing conditions which come on late in the development of certain maladies. The pathologic anatomy of paralysis agitans is nothing more than a description of the pathology of the aged or those who die of exhausting diseases. Dr. Brown's paper is to my mind one step in advance along this general line. With regard to the differentiation which he attempts to make between functional and organic paralysis, I will try to point out what I conceive to be an error in his paper. He says that because the paralysis disappears and again returns, is to him evidence of functional derangement. While that may be according to the definition which the Doctor would attach to the term, functional, we know a vast number of organic lesions which pursue this course—paretic dementia, locomotor ataxia, and many other lesions which are associated with demonstrable and early pathologic changes in the nerve cells and nerve fibers, associated with such remissions as were noted in his case. I think also the Doctor's inability to distinguish between the possibility of a peripheral lesion and one involving the spinal cord is a point well taken, and one often lost sight of in the pathology of spinal lesions. I am confident that there is no means of absolutely distinguishing between peripheral nerve lesions and those which involve the anterior horns. I would differ, however, from the Doctor in regard to this being a purely functional lesion, but would not have too much importance attached to that difference, because this term, functional, and the term organic, are used altogether too loosely. I think there is a difference in the mind of almost every observer. One gives a certain definition and weight to the term, functional, and another a somewhat different one, and until the term is more definitely employed I certainly would not attach much importance to it.

I think the case is an exceedingly interesting one, and one that has been carefully observed.

DR. JAMES G. KIERNAN—As to this question of functional and organic conditions, I agree with both Drs. Brown and Moyer in the main, since I do not think there is such a wide difference as might at first be assumed. What is beginning to be true of general neurology was true of psychiatry. At one period lesions were found to explain every form of insanity; at another period there were no lesions at all, and at still another there were doubtful lesions. In dealing, for example, with cerebral conditions which would correspond with the so-called functional spinal conditions mania, melancholia, etc., it is practically settled now that in about 15 per cent. of the cases changes only are present, which are secondary to those which went on in the primary stage. The way to avoid controversy regarding functional and organic, which terms run all through pathology, is to introduce the term and recognize the condition which is present. This change or condition may be designated bio-chemical. Ap-

plying same analogy with regard to the psychoses to the neuroses, which are not very well defined pathologically, conclusions may be made backward from secondary conditions to what bio-chemic change must have happened in leading up to them. More than twenty years ago, Charcot described a case in which hysterical paralyses, implying a spinal element, had so long continued that they had been followed by direct spinal lesions which were secondary to disuse and not primary, as was evident on autopsy being made and revealing certain conditions. Dr. Brown's paper raises the question whether in a large number of these spinal conditions (I will admit this position is taken largely by railway surgeons) there is not a temporary bio-chemic condition which simulates, for the time being, almost all organic conditions. I am strongly of this opinion. For instance, a spinal condition may occur in neurasthenics. So-called spinal neurasthenia may simulate locomotor ataxia completely. When I say completely, I mean even the lightning-like pains, which in fact here are not true lightning-like pains, but topoalgia. When these conditions are continued long enough, in the place of a bio-chemic condition we have a condition of excitation of the local conditions which results in periodic organic change.

With regard to the case under discussion, a somewhat similar one was described about three years ago by Salemi Pace, under the peculiar title of "spinal amnesia." He intended to convey the idea by that term that some of the spinal centers temporarily, as it were, had forgotten their function under certain conditions of shock function, which was gradually regained, the manifestations, however, meanwhile simulating various well marked myelitic conditions and sclerosis of the posterior horns. If the claims made by the railway surgeon could be accepted this condition would be ideally represented. Over-exaggerated as these claims are, since the neurasthenic element is made to simulate everything from locomotor ataxia to myelitis, there are conditions where it may do that. I have been very incredulous as to these conditions, yet a year ago in consultation with Dr. Haskell, of Alton, I saw a case in which every one of the symptoms of locomotor ataxia were present, exclusive of the eye conditions. There was hyperemia of the optic disc, but no other change evident in ophthalmologic examination. There were bladder and rectal symptoms; the bladder symptoms were clearly of psychic origin. Up to this time the urine had to be drawn with a catheter for two weeks. I was satisfied it was one of those rare conditions of traumatic neurasthenia; the patient having developed all these symptoms subsequent to an injury which he had received from his own machinery. He was unable to pass urine without catheterization for two weeks. I was sure there was a psychic element in the case. The night after I saw him the catheter was unnecessary and the man went steadily on toward recovery. The knee jerks were absent, but subsequently reappeared.

In another case which was sent me by Dr. Ribert, of Omaha, the diagnosis of locomotor ataxia was positively made. The man had a gait similar to an ataxic, except it differed in that after he started to walk, and was observed closely, the gait got worse; whereas the ataxic gait, after the man gets started, gets better; in other words, the ataxic makes his cortex do the work, to a certain extent, of the spinal cord. This case had trouble of accommodation, and had hyperemia of the optic disc which had been diagnosed as optic atrophy. He had topoalgic pains which closely resembled the lightning-like pains of locomotor ataxia. That man entirely recovered under the Weir-Mitchell treatment, and static electricity.

A large number of temporary spinal disturbances, occur in lues, diabetes, diphtheria, etc. I am inclined to believe that in almost all the infectious diseases when the knee jerks

disappear conditions which closely simulate organic diseases occur but recover. These cases indicate that in the spinal cord a bio-chemic condition may occur which is not permanent, therefore is not organic, which closely mimics, nay, which precedes all these organic conditions, but which may recover under appropriate treatment. This would explain one of the phenomena everybody has noticed, the cure of "locomotor ataxia" by the quack, the religionists and the faith cures.

DR. JAMES A. LYDSTON—A few points suggested themselves as the paper was read. In the first place it seems with respect to the diagnostic manifestations in the case referred to, that we are too prone to come to a positively definite conclusion in our diagnoses, for the reason that we only have symptomatic phenomena to guide us. It is all very well for us to talk about diagnoses after our patient is dead and the necropsy table shows us various pathologic changes to guide us; but we are delving somewhat in unknown realms, particularly with respect to the cases referred to in the paper this evening, for we know with reference to the diagnostic manifestations of spinal lesions that we do not always have positive unmistakable symptoms to guide us. Particularly is this true with respect to tabes dorsalis, in which we know that in the majority of instances in the early stage there are no diagnostic symptoms to guide the neurologist in coming to a definite conclusion. And it is here that we find the ophthalmologist comes most actively into demand, for in a certain percentage of instances in which tabes dorsalis and various other spinal phenomena are at issue, the ophthalmoscope is the only means at our command of determining positively the diseased condition. It is particularly true with respect to these spinal lesions, and as I said at the outset of my remarks, it is only by careful examination on post-mortem that we find gross or microscopic pathologic changes to account for the various symptomatic phenomena that have caused the patient to consult us with reference to his condition. I have in mind at this moment, a gentlemen, a prominent business man in the city of Chicago, who to-day is suffering with tabes dorsalis and does not know it, nor does he deem it necessary to consult a neurologist with respect to his condition. It seems to me, that in view of these anatomic and pathologic considerations we must consider that, however apparent the disease is of a functional nature, it may be accounted for by circulatory and nutritional changes, and that these changes are caused by some focus or minute foci of disease at some point or points in the spinal cord. These remarks are substantiated by microscopic examinations, anatomic investigations and by physiologic occurrences. Another point that I wish to call attention to is the fact that the knee jerk is not always an absolute test in these cases; as the individual who is suffering with spinal disturbance may in some cases have no disturbance of the knee jerk that can possibly and unequivocally be defined. So that I would say, in conclusion, that cases of apparent functional spinal paralysis are evidences, no doubt, of some pathologic change at some point either focally, or diffusely distributed throughout the cord or the cortical substance.

DR. H. M. BANNISTER—I can add very little to this subject except to confirm what Dr. Kiernan has said by giving my own experience not quite so striking as his, but still in the same general direction. A case occurred in my observation in which there was typical locomotor ataxia, no symptom lacking so far as known at the time, yet it had not been recognized by the patient or his physician. The diagnosis was agreed upon, and although at that time the specific nature of tabes was not generally believed in, I suggested and advised the use of specific treatment. The man improved and died eight years after; I do not know exactly

what his condition was during that time, but I think he died of a complication of spinal disease.

The other case I will refer to bears closely on Dr. Kiernan's case. The patient was one of a neurotic family; one relative committed suicide, another was subject to various nervous troubles, two sisters were arthritic in the last degree, and he himself was subject to attacks of epileptiform migraine sometimes simulating true epilepsy. In connection with his attacks, occasionally he would have symptoms of spinal disease strongly marked—the girdle sensation, exaggerated knee jerk, disturbance of the bladder, etc. I do not recall all the symptoms at this time, but they were very suggestive of myelitis. They all soon passed away and left him well for weeks or months at a time. In connection with these attacks, one peculiarity of the case was that the knee jerk and deep reflexes were expressly exaggerated and the testing of them was a serious matter to him. It threw him entirely off his balance. All these symptoms were temporary, lasting from a few days to a week or two, and recurring at irregular intervals of weeks and months. The case was one which I considered was largely neurasthenic, complicated, however, with more serious nervous troubles closely approaching attacks of epilepsy.

DR. BROWN (closing the discussion)—The term functional disease has a somewhat loose significance. I employ it to designate a disturbance of the function of an organ when by our present methods of investigation no definite pathologic change could be demonstrated in that organ. For the reason stated, it is pretty evident that in this the disease is spinal, and it is hardly conceivable that inflammation could have advanced far enough to produce the symptoms described and then disappear so as to permit a prolonged and almost complete resumption of the natural functions. That the functional disturbance of the cord from which this patient has suffered may, so to speak, herald the approach of permanent organic changes seems to me not improbable, and if so it ought logically to be considered as the beginning of organic disease, while at the same time it is functional within the meaning of the term as above defined. Strictly speaking, the existence of functional disease may be doubted, but nevertheless if used as defined above it is a very convenient term.

## THE ETIOLOGY AND TREATMENT OF INTERNAL STRABISMUS.

Read before the Section on Ophthalmology of the College of Physicians, Philadelphia, Oct. 16, 1894.

BY HOWARD F. HANSELL, A.M., M.D.

PHILADELPHIA.

I can not hope to discuss this extensive subject exhaustively, and I shall, therefore, limit my remarks to a brief consideration of functional internal strabismus arising from the unconscious constant contraction of the ciliary muscle in its effort to sharpen the blurred retinal image of the hypermetropic eye. No theme in ophthalmology has received more attention. A perusal of the literature of the last few years impresses the reader with the unanimity of authors as to their belief of the origin of squint and its proper treatment; yet shows great diversity of opinion 1, as to the part played by amblyopia, whether a cause or effect; 2, the result on vision of tenotomy, and he can not fail to remark that no important or decisive progress has been made since Donders' time, nor are we nearer a solution of the vexed questions than he was. It is worthy of note that thirty years have passed away and our knowledge of the true nature of internal squint has not been materially increased. No such stagnation marks the history of

other branches of ophthalmology. We boast of our progress and justly, for has not the ophthalmoscope revolutionized the study of intra ocular, intra-cranial and constitutional diseases, and cocain and antiseptics the surgery of the eye? But hypermetropic squint, notwithstanding conscious failures in its cure, remains where Donders left it. His great discovery is accepted by the ophthalmic world. The most eminent authorities believe that hypermetropia causes squint. The exceptions are a very small minority. For my part do not question it nor, I believe, does any ophthalmologist within sound of my voice.

Does amblyopia precede or follow the appearance of squint? Is it the cause of the inward deviation or the result of the non-use of the eye? Strabismic weakness of vision or amblyopia is thus defined by Alfred Graefe: "During the existence of a strabismus or after spontaneous or artificial cure, the vision of one eye is diminished below that of the other, and close examination will reveal no cause or one entirely inconsistent with the grade of the vision." He ranges himself in opposition to those who say it depends upon the non-use of the eye or upon the uninterrupted dragging of the retina or nerve by the abnormal convergence, and agrees with Knapp that the unequal action of the external muscles does not develop astigmatism of the cornea and thus produce lessened vision. The arguments he uses are familiar and need not be repeated. He believes that amblyopia is congenital and of central origin, and that hypermetropia is the prime cause of squint, which is maintained by a shortening of the muscle; that but little improvement of vision can be expected after tenotomy. In those cases of amblyopia without squint, he has been able to determine an early squint, which spontaneously disappeared.

Stilling's plausible theory of the position of rest as the cause of strabismus does not seem to have gained adherents. It is scarcely tenable. It is true that, as he says, the bounds of relative accommodation have been overstepped in strabismus, and binocular fixation is no longer a factor in controlling the position of the eyes, but this condition is induced by some antecedent power in active operation, such as hypermetropia, or by some anatomic peculiarity. The squinting position is, no doubt, a subjectively comfortable and restful one, since it enables one of a pair of misshapen eyes to assume the position in the orbit made necessary by the functional, and later anatomic shortening of the muscle. The factors he quotes as corroborating his view—the axis of the orbit, the position of the entrance of the optic nerve and the topographical relation of the fibrous and soft parts—have been used as arguments by those who believe the position of rest is divergence. The homonymous images discovered by experiments made with his own and friends' eyes by momentarily opening and closing the lids while gazing at a star, or light, or by artificial diplopia by Graefe's test, indicate simply the presence of a common muscular anomaly—esophoria, and can not properly be compared with results obtained by examination of a similar number of subjects while asleep or under anesthesia. Before cocain was used in ophthalmology, it was no unusual occurrence to observe, during anesthesia for tenotomy, that the squint had entirely disappeared when monocular, or had been transferred to the other eye. Schneller, in opposing the origin of squint out of "elastic superiority," and his expressions apply as

well in disproving Stilling's theory says: "I remembered that strabismus either disappears or becomes materially lessened in the condition of rest. Yet more marked is this, in deep narcosis, when every active movement ceases. Every convergent squint is lessened; in some entirely ceases, in a few goes over into divergence. It is impossible to determine the effect of operation under narcosis. Not only does convergent and divergent squint diminish or disappear in many cases, but is never, so far as I know, increased. The same happens in the dead. Weiss reports a case where the convergent squint materially lessened in the dead. Also, I remember having seen, during life, a squint which was gone after death." Gardner, of Chicago, in a short paper in *The Archives*, in answer to Stilling's paper, says that squint which is found with amblyopia *acquisita* is usually the divergent form, arising in conformity with Nature's law that predicates that when an organ is not used, its function is gradually lost. "If one eye has become blind from one cause or another, the struggle for binocular vision ceases. When the good eye is directed to an object where convergence is necessary, the blind eye simultaneously converges by force of habit and in obedience to identical nerve stimulation, but as the object is not seen, convergence of this eye becomes unnecessary, and gradually it becomes unsteady, then lags behind and passes into a relative divergent strabismus which may or may not become absolute. The exceptions to this rule are those cases which have enough hypermetropia to induce pathologic convergence, when the amblyopic eye assumes the convergence. These are cases of amblyopia congenita and not *acquisita*." He denies Stilling's assumption that when one eye has turned in, the relation of accommodation and convergence is abolished. On the other hand, the normal exercise of the accommodation in the straight eye is possible only because the squinting eye assumes the convergence of both. Again, it is shown by numerous reliable writers, that it is possible to bring about amelioration or cure of the squint by resumption of the function of both eyes through the continued use of atropin and properly fitted glasses. Now, if convergence were the position of rest, all inducement to recover binocular vision would be wanting and a cure would be in opposition to Nature's law. Moreover, if abnormal convergence were the position of rest of hypermetropia we would find, not only convergent squint in hypermetropia but that it would be more common in hypermetropia than it really is.

The coördination of the visual axes, or the want of it, depends upon several conditions, namely, the refraction, the vision, the relative strengths of the several external muscles, the axes of the orbits and the innervation, including the conductivity of the nerves, the functional activity of their nuclei and of the cortex. Since our study deals only with purely functional deviations, we need consider only the bearing of the refraction, the vision and the innervation:

1. *The Vision*.—Congenital amblyopia, without anatomic changes in the media or fundus that can be detected by the ophthalmoscope or any other means, is associated with internal squint in about 75 per cent. of all cases. Vialet (*Arch. d'Oph.* Vol. xx, p. 289) analyzed 150 cases of strabismus, and found 122 with amblyopia. He says that in eight of fifty-one repeatedly examined cases, improvement of vision

began after tenotomy, and mainly in convergent strabismus with amblyopia of brief existence and low degree. We can only speculate concerning the relation of amblyopia to squint. We must confess ignorance of its true nature and of its etiologic connection. It is generally conceded to be congenital, though the misleading surname "ex-anopsia" still clings to it. That it can be benefited by operation is doubtful, "a pious hope rather than an assured expectation." (Noyes). That it does improve and in a short time disappear so that full acuity of vision is finally acquired in cases where, through accident, the good eye is destroyed, is illustrated by two cases reported by Johnson—one in the transactions of the American Ophthalmological Society of 1893, the second, in the *American Journal of Ophthalmology*, January, 1894. Why, then, does not the same good result ensue after tenotomy? For two reasons: 1, because the parallelism of the axis of the squinting eye with that of the other is seldom obtained—it is simply approximate and conjectural; and 2, there is no incentive to binocular fixation. The patient with sharp acuity in one eye will rely upon that eye for information of the outside world. The dull image in the cortex or visual center, even though that on the retina is accurately defined, will be recognized, if perceived at all, as an annoyance to be suppressed. A patient now under treatment, illustrates this point. Vision of L. is 20-15; R. 20-40. I have succeeded by various operations, in making the axes meet at several distances, but he sees the sharp clear image of the candle flame of the L. in the center of the large, indistinct, retinal or cortical image of the R., and instantly dismisses the latter by an inward or outward rotation of the R. The final result is only cosmetic. I can not agree with Fulton (Transactions, Ninth International Congress) and with Landolt, that vision of the squinting eye is improved after tenotomy, binocular vision being restored, and if the eye continues to squint, vision diminishes, but fully coincide with Wadsworth (*Boston Medical and Surgical Journal*, Jan. 20, 1887), that amblyopia is not caused by squint or that amblyopia improves after squint is corrected. I am inclined to go a step farther, and assert that convergent strabismus with amblyopia is seldom, if ever, permanently cured by tenotomy of the internal muscles and correction of ametropia, however accurate. Stereoscopic exercise, upon which Landolt lays stress, is a useful adjunct in restoring muscular fixation in heterotropia, by exercising weakened muscles, but is of very little service in developing the function of a congenitally imperfect eye.

2. *The Refraction.*—Seventy-five to ninety per cent. of convergent strabismus is found in hypermetropia. Snell (*British Medical Journal*, 1887) makes a higher proportion. He says convergent strabismus stands in direct connection with hypermetropia in 95 per cent. Donders has shown that the relation or connection between hypermetropia and internal squint is that of cause and effect, and his theory has been almost universally conceded to be the true one. Internal squint is occasionally found in E. and in M. In this small minority of cases it would seem as though some other hypothesis would be necessary, but this need is only apparent. It would doubtless be found as others have said, that hypermetropia preceded the M, and again where a myopic correction is worn, the strain on the accommodation of too

high a glass—or the attempt to correct, subjectively, an existing astigmatism, may produce exactly the same effect on convergence as the effort to overcome a shortened axis. Again, some writers attempt to disprove the truth of Donders' theory by claiming, that according to it every hypermetrope should at some time of his life have internal squint. This objection can be successfully refuted. Valude (*Archiv. d'Oph.*, Vol. x, No. 4), teaches the true doctrine of the relation of hypermetropia to internal squint, when he says that convergent strabismus does not depend upon ametropia alone, but that a neuro-pathic disposition is an important, sometimes the principal factor. Moreover, every one who has investigated the condition of the external muscles is convinced that esophoria is a very common anomaly in hypermetropia, and the phorias, or tendencies to squint differ from the tropias or actual turnings, simply and only in degree. The exceptions are rare when we find equilibrium in association with any material error of refraction. Thus we are again brought face to face with the incontrovertible fact, persistently and successfully advocated for the past twenty years, preëminently by the leading ophthalmic surgeons of Philadelphia, as was so ably presented to the Fellows of this College last spring by its honored President, that errors of refraction, particularly hypermetropia and astigmatism are the underlying cause of anomalies of muscular action and that no effort directed toward a restoration to equilibrium can be successful unless attention is first given to relief of accommodative strain by constant wearing of as near as possible a full correction of the optical defect. The general profession is under deep obligation to Weir Mitchell, Dyer, Norris, Thomson and others for the light thrown by their clinical studies on obscure intractable headaches and other disturbances of the nervous system, which showed that their cause was to be sought in accommodative or muscular strain. Ulrich concludes that squint is prevented in hypermetropia by reason of the muscles themselves through a relative weakness of adduction, corresponding in degree to negative accommodation or an absolute muscular incapability and the intellectual necessity of the visual act, which demand the fulfilled function of binocular vision and rebel against the disturbances of diplopia incident to commencing internal strabismus.

3. *The Innervation.*—Full binocular vision in uncorrected hypermetropia depends upon the accommodation, the convergence and their relation to each other. Whenever the desire for binocular vision is impossible of gratification, for instance, when excessive accommodation demands excessive convergence, or when the hypermetropia of one eye exceeds that of the other by several dioptries—2 to 4—or this desire has never existed, the axes of vision are turned toward, rarely from, each other. Thus we have two classes of hypermetropic squint—the alternating and the constant. Again, as has already been alluded to, the disturbance of the relation of accommodation and convergence in hypermetropia does not necessarily induce an obliquity of one of the axes, but may develop latent squint or esophoria. In the latter the desire for fusion is sufficiently strong to equalize, under pressure, abduction and adduction; in the former, abduction has yielded to the greater physiologic force of adduction. In normal muscular action and innervation, the muscles are in equilib-

rium—adduction equals abduction; R. sursumduction equals L. sursumduction, but, if by reason of the refraction of one or both eyes, unequal accommodation, or constitutional disturbances, the innervation or the power of the muscles to respond to the innervation become deranged, we have a pathologic condition of turning or tendency to turn. Here the tests employed under normal conditions to measure adduction and abduction are no longer reliable, and efforts to measure cerebral function, such as fusion force, by constant unalterable agents, like prisms, are attended with varying and inconstant results. Therefore to say that in heterophoria, adduction equals so much, abduction equals so much, and thus to estimate the strengths of the separate muscles is not consistent with scientific principles. While we measure adduction we are also measuring abduction. A prism angle held before one eye will, if not too high, induce contraction of the internal rectus, rotating the cornea inward. The opposite internal rectus will also be stimulated to contract, but if we want to hold single images the external rectus of that eye must contract equally to hold the axis straight. This, again, by stimulating, abduction excites the external rectus of the first eye in equal degree, or, the contraction of the internal rectus of the eye before which the prism is held, acting in lateral movement, stimulates the external rectus of the opposite eye. This can not rotate, but must be held fixed by its internal rectus, which in turn excites its corresponding external rectus in lateral movement in the opposite direction. Thus when we say adduction equals 20 degrees, we mean adduction and abduction are both equal to 10 degrees and each muscle overcomes 5 degrees. In testing sursumduction the same difficulties are met with and the physiology is still more obscure and complicated because eight muscles are involved in each experiment. In actual deviations of one of the axes, adduction and abduction can not be measured by prisms, since there is no binocular fixation and can be only approximately estimated by observation of the lateral movements of the balls. To learn the exact amount of deviation, it is essential: 1, that the patient shall be compelled by all available means to recognize double images of a candle flame at twenty feet and nearer distances; and 2, that the distance between the false and true light be measured by the angle of a prism or by lineal measurement. In manifest squint this distance will be found to vary but slightly from day to day, but in those cases which lie in the borderland between latent and manifest squint, when binocular vision alternates with diplopia the angular deviations are constantly changing, according to the innervation and fusion force exercised at the time of the examination. By this method of examination it will be found that in every case of internal strabismus, the squinting eye is rotated upward. The image of the candle flame will fall in the retina in a plane higher than the plane of the fovea, hence will be seen lower than the true image. In pure internal rotation the images should be on a horizontal plane. This can occur only when the patient's attention is fixed simultaneously on both images, a condition never found in manifest strabismus. In monocular squint, by which I mean cases in which one eye is always used in fixation and the other always is turned inward, the squinting eye is rotated obliquely inward and upward, and the false image maintains a

position lower than the true. In alternating squint, where either eye may be used in fixation, the squinting eye is rotated inward and upward, and when the fixation is transferred to the former squinting eye the inward and upward deviation is also transferred. These phenomena can only be interpreted by pursuing to its proper conclusion Donders' theory of hypermetropic squint.

Abnormal convergence is induced through the supra-normal contraction of the ciliary muscle necessitated in the effort for clear vision. The stimulus thus received by the ciliary branch of the third nerve is communicated to the several nuclei of that nerve in the floor of the fourth ventricle and an order for corresponding contraction sent out to all the muscles supplied by that nerve. If this stimulus could be limited to the interni, simple convergence would result, but clinically, it is shown that the resulting contraction is far more complicated and includes the superior and inferior rectus and the inferior oblique. The simultaneous contraction of these muscles rotates the cornea upward and inward—inward because the opposing external is quiescent, upward, because the two elevators thus set into action overcome the one depressor.

In alternating squint, the transference of fixation involves necessarily a transference of the strabismus. The cornea of the squinting eye is directed inward and upward and not inward alone. The degree of hypertropia bears a constant relation to that of esotropia. I have never found it less than 2 degrees and often as high as 6 and even more. If Donders' theory is correct that primarily hypermetropia and secondarily the accommodation in hypermetropia induces squint, it follows that it must also be the cause of the hypertropia. This condition has often been observed and noted without explanation. I have deemed it a matter of sufficient importance to make it the subject of several articles: 1, because hypertropia is as common as esotropia; and 2, because cognizance of the upward deviation demands a modification of the usual methods of treatment, as well as of the prognosis.

I agree with Carter and others in believing that in all cases of internal squint in which operation is advisable, the tenotomy should be divided between the two internal muscles, and that no permanent good result can be obtained by confining the procedure to the eye which at the time of the examination squints. In constant squint, where the patient can never by reason of amblyopia, voluntarily transfer fixation, binocular vision can scarcely be expected, but the best result is obtained by tenotomy of the interni, the superior rectus of the squinting and the inferior rectus of the fixing eye. It may also be necessary to suture the external rectus of the squinting eye. In alternating squint, where amblyopia is never present and the patient arbitrarily chooses either eye for fixation, binocular vision can be obtained as a permanent result in the great majority of cases, by tenotomy of the interni. The want of equilibrium of the vertical muscles is only apparent and should not receive direct surgical treatment.

In all cases, without exception, the error of refraction must be carefully corrected and a full correction worn, and since the curve of the cornea has been known to be modified by tenotomy, the final correction should be made after operation. In very young persons, tenotomy should be postponed until suffi-

cient time has elapsed to demonstrate the futility of restoring binocular fixation by atropia, glasses, prism and stereopticon exercises and other measures.

My conclusions, scattered here and there through this somewhat rambling paper may be tersely stated as follows:

1. Amblyopia is congenital and not acquired; is not improved by tenotomy when high or of long duration; is always present in monocular squint; is not a factor in alternating squint; can be replaced by full acuity of vision after the hitherto good eye has been rendered by accident or disease inferior to the squinting eye.

2. In monocular constant squint the cornea of the squinting eye is turned upward as well as inward.

3. In concomitant or alternating squint, the non-fixing eye is turned upward as well as inward, and with transference of fixation there will be a transference of both the upward and the inward deviation.

4. Donders' theory, extended to include all the muscles supplied by the third nerve, and not the interni alone, is a sufficiently satisfactory explanation of the upward deviation.

5. Atropia and full correction are, in many cases, curative agents.

6. All operations should be done under cocaine anesthesia.

7. In monocular squint, vertical equilibrium must be restored by tenotomy, while in alternating, division of the interni is sufficient.

## THE MENTAL CONDITION OF ARTHUR DUESTROW.

A REPORT SUBMITTED TO HIS ATTORNEYS.

BY CHARLES GILBERT CHADDOCK, M.D.

Professor of Diseases of the Nervous System, Marlon-Sims College of Medicine; Member of the American Medico Psychological Association; formerly Associate Medical Superintendent Northern Michigan Asylum for the Insane; Neurologist to the Rebekah Hospital; Fellow of the Chicago Academy of Medicine, the Detroit Academy of Medicine, etc.

At the instance of Hon. Charles P. Johnson, his attorney, I examined Arthur Duestrow, with a view to determine whether he was sane or insane. The circumstances to consider were that the client stood indicted for the brutal and motiveless murder of his wife and child; that he had been in confinement, in jail for several months; that he had manifested symptoms indicative of an abnormal mental state; and that the plea of insanity was the only possible preventive of punishment for his atrocious crime. These circumstances made it obligatory upon me to examine him with special reference to the possibility of his feigning insanity as a means of escaping the legal penalty that threatened him.

I visited the prisoner several times in the jail at the Four Courts in St. Louis. He received me kindly and was on all occasions when I was with him polite in manner and remarkably communicative. He always expressed himself with freedom and with every outward sign of sincerity. He willingly submitted to my physical explorations, and gave me every opportunity to satisfy myself.

*Physical Examination.*—He was 26 years of age, and his appearance accorded with his years. He was in a fair state of bodily nutrition, though he weighed several pounds less than he did at the beginning of his incarceration. Height, nearly six feet. His color was good, and his circulation perfect. The heart was found to be normal; pulse rate, normal. There were

no signs of pulmonary disease of any kind. His appetite was excellent and there was no evidence of gastro-intestinal disturbance. There were no symptoms to indicate a diseased condition of the kidneys. His general physical development was good, the muscles were quite firm and fairly developed, considering his past confinement; the skin presented no anomalies. Inspection revealed no marked physical sign of degeneracy. His head was slightly above the average size, and presented no asymmetry. The ears were well formed and the jaws did not deviate markedly from average standards in form.

*Nervous System.*—There was no indication of paralysis, paresis or incoördination; no tremor. Cutaneous sensibility was normal. The knee jerks were present and equal; the pupils reacted normally to light and accommodation, and were of equal and normal size. Articulation was perfect—distinct, unhesitating; no fibrillary twitching of tongue or lips. Sight and hearing were perfect, and there was nothing to indicate anomalies of any of the special senses. No complaint of pain of any kind was made, nor of vertigo. There were no scars indicative of epilepsy.

From these findings I assert that Arthur Duestrow was not suffering with any functional or organic disease of the peripheral nervous system or spinal cord; that there was no organic cerebral disease in his case; at least that the presence of such anomalies in him were not discoverable by any means known to science. Thus the only remaining possibility of disease was that of functional cerebral disturbance.

*Cerebral Functions.*—Emotional state or feelings: There was no sign of depression of feeling—an absence of all the outward expressions of a feeling of sadness or melancholy; the emotions changed with the change of thought, showing no sign of affective inhibition. In striking contrast with such a possibility, his mood, or state of feeling was, on the whole, one of mild expansiveness, expressed in an unmistakable show of satisfaction with self and a manner indicative of a sense of superiority to others.

This emotional state was one that could have no rational root in his circumstances. He was in confinement, deprived of all the amenities of life, associated with the lowest class of men and awaiting trial for his life. Instead of remorse, sorrow, anxiety, fear and depression, his manner, facial expression and conversation revealed a state of mental feeling in striking contrast with these. Had he been an innocent man he would normally have had great cause for fear, since in the newspapers which he received daily he read of the intense popular prejudice against him; as a malingerer, he would necessarily have recognized the small chance of escape he had, even though he simulated insanity to perfection. All these circumstances tending to bring him to some expression of doubts, fear or anxiety for his future, were absolutely without their normal effect on him. On the other hand, the absence of these natural feelings was not occasioned by indifference of his future. The ideas he expressed were in complete accord with his general mood; he was hopeful, ambitious, proud and self-assertive, and the ground for all these was evident in the thoughts he freely expressed, which, at the same time accounted for the apparent absence of remorse and regret. His feeling of satisfaction was so marked and so predominant as to perfectly withstand the presentation and emphasis of facts which would dispel it in any normal person; pervading

consciousness so exclusively as to overcome any tendency to irritation and anger that would naturally flow from strenuous contradiction and opposition to his views. If this remarkable state of feeling was assumed for the purpose of deception, it was done with a perfection and unchanging persistency that absolutely defied its differentiation from a genuine emotional state.

Aside from this state of mild emotional expansiveness, there was no exaltation of feeling in any way resembling the emotional state, characteristic of mania and maniacal states. Therefore, I pronounce the prisoner free from mania and melancholia, and from any disposition to feign either of these.

To form a judgment of his intellect, conversation was used to test his powers of perception, attention, memory, imagination, reasoning and judgment. His perceptions were lively and more or less accurate; he had fair power of attention, his thought was quite clear, his reasoning logical, and he displayed remarkable activity of imagination—all with reference to the premises which formed the material of his mental operations. He entertained a great variety of ideas of intricate construction and complicated association. These facts were sufficient to demonstrate that the prisoner was not afflicted with any form of mental weakness or confusional insanity, and that he made no effort to simulate such a disease. The forms of insanity incident to the originally normal brain having thus been excluded, the inquiry became reduced to the existence of the real or feigned existence of some degenerate form of mental disease. Of these forms, the foregoing considerations, taken with other evidences—which need not be enumerated—have already excluded all but one; namely, depressive reasoning insanity, periodical and circular insanity, and the mental diseases from the neuroses, epilepsy, hysteria, etc. Thus by exclusion it was certain that he was sane, or had or was feigning the only remaining form of degenerate insanity—paranoia.

Paranoia is the name of a *chronic progressive* mental disease, usually manifested in systematized delusions that are of primary origin; that is, delusions that do not arise out of preceding mental depression or exaltation. Commonly this disease is a result of conditions inherent in the brain organization of the individual which determine the form of the disease. Study of cases of paranoia shows that there is always a history of mental symptoms which antedate the development of the perfected delusions, and often other symptoms of a vicious constitutional state of the nervous system in general; and to these are added in many cases the existence of nervous and mental diseases in ancestry that have been influential through heredity. However, paranoia may arise in persons whose heredity is in nowise at fault, and in this case it is usual to find that some decidedly injurious influence has affected the individual early in life in such a way as to lastingly and inherently harm the nervous constitution. Since the constitutional defect which underlies paranoia is imperfection in generation and development, paranoia, with other mental diseases of like origin, is called degenerate. The degeneracy at the bottom of paranoia varies in degree, and we observe corresponding variations in the mental symptoms. Thus the deeper the degeneracy, the earlier the mental disease appears, and the more sure and rapid is the progress to a condition of permanent mental weakness.

The delusions of paranoia all concern the person directly. They are of two kinds: Delusions of persecution and delusions of grandeur. Again, the earlier in life paranoia appears, the greater the chance that the delusions will be of a grand character; hence primary delusions of grandeur indicate deep degeneracy and presage early development of permanent dementia. Arising late in life, the delusions of paranoia are almost certain to be of a persecutory nature, and their character may remain unchanged throughout life. Where primary delusions of persecution arise early in life and are on a deeply degenerate foundation, they are apt to change in character, and this change affords a trustworthy indication of the further course of the malady. This change of delusions of persecution is called the *transformation*. This consists of a change of primary delusions of persecution to delusions of personal aggrandizement. The transformation, whenever it occurs, is a sign that dementia will ultimately come on, and the earlier it takes place, the more rapid the progress to mental weakness will probably be. When the transformation has taken place, there is not necessarily an entire absence of the former persecutory ideas; rather they are overshadowed by the grand delusions. Occurring with the change of ideas, there is a corresponding change of feeling. While persecuted the paranoiac is morose, sullen, silent, suspicious, treacherous and often violent; after the transformation, he becomes talkative, friendly, self-satisfied, proud and important, and may even go so far as to excuse his former imaginary persecutors.

The process by which the transformation is accomplished varies. It may result from a chain of reasoning; it may take place suddenly as a result of an hallucination, a dream, etc. Whether the result of a reasoning process or not, the secondary delusions of grandeur are always intimately logically connected with the primary delusions of persecution. Thus one person concludes, as the logical outcome of his persecutions, that he is entitled to some great privileges of honor, position or fortune which usurpers are in the enjoyment of; and he attributes his persecution to those who occupy the place which he fancies belongs to him. Under appropriate surroundings of life and circumstances of education paranoiacs, after the transformation, become in their thought kings and princes, religious reformers, political enthusiasts, heirs to great estates, great inventors or discoverers. Love plays a prominent part in some cases. It is customary in text-books to make numerous classes of paranoia in accordance with the particular nature of the ideas expressed, but such subdivisions are of very minor importance; and besides in a single case we frequently find a combination of ideas which would require very numerous descriptive terms. Thus in all cases of paranoia, we find sexual elements; we rarely miss a distinct philanthropic motive, after the transformation; religious ideas are but exceptionally wanting; and political views of a delusional character are as common. The reason for this expression of false ideas on so many subjects lies in the fact that the whole mental personality is implicated, and therefore all thoughts and experiences are necessarily and intuitively brought into harmony with the fundamental mental tone.

In paranoia the logical and associative powers of the mind are not necessarily impaired; rather mental associations are facilitated as a result of the extra-

ordinary intensity of consciousness characteristic of the disease. This intensity of consciousness of a direct personal kind accounts for the instantaneous mental assimilation of all ideas, no matter how incongruous or contradictory, and the forcing of them into immediate association and logical relationship with the predominating delusions. Such a phenomenon as this is only possible before much mental weakness has supervened. This automatic assimilation of incongruous ideas shows that in such a case all power of critical examination of facts has been lost; and thus even here there is actually loss as well as distortion of mind.

Hallucinations and illusions, while not a necessary accompaniment of paranoia are rarely wanting, and when present they afford important sources for the creation and elaboration of false ideas.

It now remained to determine whether the prisoner presented a mental condition like that present in paranoia, and if so to ascertain whether it was a product of disease or voluntarily assumed to deceive.

The expansive mood previously described as presented by Arthur Duestrow, corresponds in all its features with that observed in cases of paranoia after the transformation has taken place. In this case the state of feeling was out of all harmony with actual external conditions. Was it in harmony with ideas entertained by the prisoner?

The prisoner's conversation was free and open; there was nothing in his manner to raise a suspicion of a lack of frankness; his mien was open and straightforward. Thus there was no difficulty in inducing him to be as communicative as desired. Without prompting, he went into a detailed description of ideas and experiences of a very remarkable character. He said that he had made the greatest discovery of modern times; namely, the fact of mind-transference and the ultimate possibilities of hypnotism and animal magnetism. By means of this discovery he was about to revolutionize all medical sciences, and liberate the world from crime, vice, and maliciousness. His discovery made clear to him much in his own life that had before remained inexplicable. Hypnotic influence and malicious thought-transference had been used by his enemies to control and persecute him. Thus he had been induced to drink, and injure his wife and child. After his incarceration began, the same influences had been used to persecute and annoy him constantly, thus driving him to attempt suicide. Machines, telephones, batteries, etc., had been used in this way, by placing them in hiding in his cell and elsewhere; and he had been made to have hallucinations and delusions by the same means. This state of unmitigated persecution had continued until he had suddenly discovered the nature of the means used and the great preventive to overcome their malicious use. Since this sudden discovery he was still the object of persecution, but he obviated its effects by using his great preventive. He explained the prevention now as the natural consequence of his being a great pioneer in a new field, likening himself in this respect to Christ, Columbus and others. In this influence of hypnotism, thought-transference and animal magnetism he found an explanation of all diseases and the way to cure all diseases. He gave the details of an elaborate and impossible theory of the relation of the spleen to the "glandular system," the blood, the body, the convolutions of the brain, and its effect to cause and cure

disease by means of animal magnetism. His preventive consisted in his knowledge that possession of the "positive and negative sparks" would keep off the influence of "malicious thought-transference." He had become so accustomed to use this preventive that he could apply it effectually even in sleep, to save himself from persecutors who sought to gain control of him by exercising their influence on him while he was presumably unconscious and unable to protect himself. He asserted that all persons who in any way looked like him, had the same thoughts, the same feelings that he had; that when he was persecuted, those like him were similarly annoyed and controlled. He explained an elaborate system of colored sparks which evidenced great imaginative ingenuity. He sought to show how he could anesthetize a person at a distance by taking chloroform himself and transferring its effects by means of thought. Since his discovery he had become able to exercise the influence on any one. He could make any person do what he willed, think any thought he desired, read their thoughts, etc., etc.

The prisoner made several attempts to display his boasted powers which was successful only in his confiding imagination. These attempts were offered as demonstrations of the truth of his assertions. He tried to tell the hour by means of the mind of a third person in sight of a public clock; to transfer the odor of a rose from a flower-shop blocks away. He told of various vulgar acts to which he had forced others by his power. There was a sexual tinge in much that he said. His discovery had enabled him to read the thoughts of men the world over, and thus he was able to foretell human events. In this way he had learned of his elevation to a high position as surgeon in the army; of his relationship to certain aristocratic persons in Germany; of his election to the College of Jesuits by the Pope for services in revealing the dire designs of members of the Church of God directed against the Church of Rome. Moreover, by the use of his powers he had converted all the physicians who deemed him insane to complete recognition of his sanity. He told how; controlled by malicious thought-transference, he had been made to shoot his wife and child, but explained that the wounds were merely superficial and that they had recovered and now understood what had forced him to act so unnaturally; he had seen his wife and child (illusions) and was therefore convinced that the proceedings against him were a farce and about to be dismissed. The effort to prove him insane was but a ruse of his enemies who sought to influence the lawyers and doctors and make them believe him crazy, in the hope to get him into an asylum. He would show at his trial that he was sane and all the doctors insane. He gave a history of himself which showed that he had repeatedly had illusions and hallucinations, and while under examination he frequently gave signs of having rudimentary hallucinations. His description of hallucinatory experiences was remarkable for its originality and for its perfect correspondence with that given by insane persons of their mental phenomena.

This recital of his ideas might be much further extended, but such a narrative could add nothing to the foregoing exemplification of the general nature and character of his intellectual operations.

The prisoner's description of his life in jail and the evidences at hand, showed that at the beginning

of his confinement he had delusions of persecution and hallucinations; that his mood, corresponding with these, was then silent, sullen and suspicious; that suddenly, after some months, a change had come which was the inauguration of his present state of thought and feeling. The persecutory ideas had persisted but had become subsidiary to the grand delusions and logically connected with them.

No kind of contradiction or demonstration caused him to change countenance or modify his views and assertions. There was perfect harmony between his grand ideas and his expansive mood.

The manner in which the prisoner conversed and defended his impossible and absurd notions was remarkable for the readiness and rapidity with which incongruous ideas and facts were accepted, distorted and explained from his delusional standpoint. The effect of trivialities in their suggestive relation to his mental operations was at once a matter of surprise and wonder to one observing it. It could not be adequately described in words. Never was there anything thus exhibited in any way out of harmony with his predominating state of consciousness. These were the most striking features of his mental condition taken with the constant display of his lack of critical powers.

In his ideas we find delusions of persecution, personal aggrandizements, sexual tinge, religious tendencies, philanthropic schemes, etc. He gives evidence of having had all the symptoms of the developments, course and transformation of the mental state seen in paranoia; of having at present the symptoms characteristic of that disease after the transformation has taken place. His hallucinations and illusions are characteristic in their minutest details of that malady. The instantaneous assimilation of all kinds of sense impressions and ideas, and their immediate harmonious association in consciousness, are again characteristic of certain stages of paranoia. Throughout all the system of symptoms he presents there is a perfection of harmony in their combination that leaves no doubt that he exhibits an exact portrayal of a definite type of mental disease, and that the type is paranoia. Were these symptoms feigned? Since they correspond in minutest detail in development and course with a very definite form of disease; and since they are of the greatest complexity, if feigned, their presence betokens the most profound knowledge of insanity, which could come only after years of study and observation of the insane in constant association with them. Such a knowledge could not be gained from books, much less imparted by word of mouth. If the prisoner can be shown to have spent years with the insane, and to have a mind far above the average, we may allow, for the nonce, that he feigned these symptoms. Allowing this, we should expect an absence of all the ordinary signs of feigning, as we do in this case. Allowing that the prisoner is simulating, with such a profound knowledge of insanity he would certainly choose an easier part to play. Mere delusions of persecution would serve the purpose of a simulator as well; there would be no need to go through the transformation; no need to bring in all ideas—sexual, religious, philanthropic, etc. However, in the symptoms presented by the prisoner there is an element which no person could successfully simulate, no matter if a master in knowledge of the insane mind; namely, that rapidity of reception, associa-

tion and delusional interpretation of all external impressions, experiences and ideas, no matter how inharmonious or contradictory they are in fact;—a process in which there is never any flaw, never anything incompatible with the fundamental state of consciousness. Such rapidity of assimilation and association of mental impressions is seen in other forms of mental disease, but never with the logical connection and systematic creation of mental combination that characterize it when present in paranoia.

The presence of this element, associated with the other mental symptoms in this case, is positive and unmistakable evidence of disease, and as positive evidence of an absence of feigning. In any case of feigned paranoia this element would necessarily be lacking; for it is impossible for a normal mind to act in this way. The normal mind, in possession of its ordinary critical powers is, as it were, by a psychologic law, forced to exercise criticism—to compare, weigh and consider; this requires time, and is shown outwardly in hesitation, delay, uncertainty, and equivocation in the expression of judgments. The paranoiac's mind, devoid of the power of criticism, has no need to weigh or consider; as it were, the explanation of any possible event that can be presented to his mind is ready, created before the event is perceived. In other words his mind receives everything automatically, is never surprised or led away from its predestined path of activity. The reason for this peculiarity lies in the fact that the operations of the mind of the paranoiac are directed by inner cerebral conditions; whereas, in a normal mind the mental activities are constantly modified by the logic of impressions coming through the senses. This process peculiar to the mind of the paranoiac, is involuntary and incapable of voluntary imitation.

The origin, development and transformation of the prisoner's delusions are sufficient to demonstrate their relation to disease; but it might be objected that some other proofs were required to show his false ideas to be insane, rather than sane delusions; for a delusion *per se* is no sign of insanity. A sane delusion is a false belief that has arisen as a result of teaching, ignorance, or erroneous interpretation of experience. Such a delusion may be so tenaciously held as to resist all powers of demonstration and argument, and require a course of careful education to eradicate it. A sane delusion may at any time become an insane delusion, when appropriate conditions arise in the individual. For example, many normal persons entertain delusions concerning so-called thought-transference. Under normal conditions this error has merely an abstract value for the mind that entertains it; it bears no concrete and immediate relation to the individual. To become an insane delusion such a false belief must be brought by the mind into direct bearing upon its operations; the person must find within himself reasons which convince him of this relation—he must interpret inexplicable inner events, activities and sensations as due to the operation of the influence which he has previously believed in only in an abstract and impersonal way. The changes within himself may be normal or abnormal; the absence of critical power which enables them to be brought into immediate relation with the false belief is always due to a diseased mental condition.

Thus in the prisoner's case, his delusions are insane

delusions because, in the abnormal absence of critical power, he brings them into direct relations with events, sensations and phenomena which are present only in his inner consciousness. These facts are sufficient to show beyond a doubt that Arthur Duestrow is insane, that he is suffering with paranoia, and that he is incapable of understanding the nature of the trial he is approaching.

I have never seen or heard of recovery in a case of genuine paranoia. I am confident that in this case an examination of the ancestral and individual history would reveal the degenerate basis of the malady. Remembering the comparatively early age (25) at which the disease reached complete development, the rapid and early completion of the transformation, and the absence of critical powers, it seems probable that dementia will supervene with comparative rapidity. By this, I mean as compared with the oncoming of dementia observed in ordinary cases of paranoia. It may be several years before the mental weakness becomes so apparent as to strike a lay observer. "Acute paranoia," so-called, is a curable disease, but to apply the word, paranoia, to any form of acute mental disease is to do violence to scientific nomenclature; there is no reason to regard this case as one of acute mental disease.

Aside from the probabilities mentioned, there are other possibilities that must be considered in this case. In any case of paranoia, remissions of short or longer duration may occur, and in such an event there is an apparent return to mental health for a time, but always ultimately the symptoms reappear, and the former delusional creations are again taken up and further elaborated. Moreover, a paranoiac may at any time simulate sanity, and that so successfully as to deceive all but the most experienced observers. The simulator of sanity reasons in this manner: "As long as I talk about my ideas, they will think me crazy and deprive me of freedom; therefore I'll conceal my ideas and accommodate myself to those who restrain me." This ruse is only too frequently successful in bringing about release from custody, and numerous paranoiacs have thus hastened from the asylum to kill some person representing an imaginary enemy. The ideas of the paranoiac are not necessarily "fixed" or unchangeable, and therefore it is to be expected that those at present entertained by the prisoner will alter more or less in time, though their general nature will not change until permanent dementia has supervened. A paranoiac may, like any man, become subject to an organic disease, such as paretic dementia; or his fundamental malady may become complicated by some acute mental disease.

Such a consideration as this, suffices to show the utter absurdity of defining a paranoiac as a person whose opinions differ from those entertained by the majority of mankind. Opinion, like a delusion, can never be a sign of insanity until it can be shown to have a foundation in disease.<sup>1</sup>

1320 Union Trust Building.

<sup>1</sup> In this report, the legal requirements restricted the writer to the condition of the prisoner subsequent to the homicide; thus an important part of the medical aspect of the case was excluded. The facts, however, show that there is alcoholism in immediate ancestry, and hysteria in immediate collateral. The previous history of the

## REMOVAL OF THE APPENDAGES AND LIGATION OF THE UTERINE ARTERY TO THE UTERO-CERVICAL JUNCTION.

REPORT OF THIRTY CASES OF A NEW OPERATION.

BY BYRON ROBINSON.

CHICAGO.

The above operation I introduced about two years ago. The technique consists in ligating the appendages and then snipping them off. An aneurysm needle armed with a double ligature is then passed through the broad ligament at the cervico-uterine junction on the inner side of the uterine artery. The one ligature is tied along the side of the uterus including the perpendicular arteries of the uterus, the Fallopian tube, round and ovarian ligaments. The other ligature is tied on the broad ligament including the ligamentum infundibulo-pelvicum. Another method consists in ligating and removing the appendages and then simply ligating the uterine artery once or twice as it courses through the broad ligament by the side of the uterus as low down as the neck. The first method is the best, as it atrophies not only blood vessels but nerves and ganglia. We have ligated the uterine artery down to the cervico-uterine junction in nearly all of the cases. No symp-

This drawing is intended to show the method of operation. The right tube and ovary have been tied by ligature 2 and removed. Ligatures 1 and 3 are introduced on an aneurysm needle and tied. Ligature 4 shows the lowest point at which I have ligated. Ligature 5 might be considered to be within the danger line. The left tube and ovary have not been removed, but ligature 1 includes the tube and artery. I have ligated the uterine artery as low as the point indicated by ligature 3 on the left side. The drawing is somewhat diagrammatic, but the arteries are as natural in their position and relations as I could draw them. Lately I have only used one double ligature to ligate the artery fully as low down as No. 5.

toms of tissue death in the uterus have so far appeared in any of the cases. In some cases pain is severe from twenty-four to forty-eight hours, but it seems due to trauma by the ligatures on large numbers of nerves and ganglia. This pain can be quieted with  $\frac{1}{16}$  gr. morphin once or twice, for the main pain is generally over in fifteen hours. This operation can be widely applied in surgical gynecology. It pro-

prisoner shows marked mental dullness, delusions of suspicion, sexual perversity and intolerance of alcohol. The double murder was presumably connected with a state of alcoholism, and the fully developed mental distortion was manifested immediately after the murder. Thus far it remains uncertain whether the crime was directly the result of delusion, or the deed of an insane man excited by a triviality to ungovernable rage.

duces sufficient shock on the circulatory and nerve apparatus to quickly atrophy growing uterine myomata. The effect of ligating the uterine arteries as they course through the broad ligament is to atrophy the endometrium rapidly—checking endometrial secretions and hemorrhage. The pelvic floor is preserved intact by this operation, obviating the danger of vaginal hernia.

In a vaginal hysterectomy made by Dr. Lucy Waite with my assistance, a vaginal hernia followed several months after the operation. This operation brings on the menopause rapidly. It followed in two months in one case. The operation leaves a functionless, atrophic, normal positioned uterus, which so far among our patients has given no trouble. This report is based on thirty operations made during the last twenty-six months. In several of the cases I assisted Dr. Lucy Waite and Dr. Bertha Van Hoosen, and include them in the report. The utility of the operation consists in the following points:

1. It checks hemorrhage.
2. It arrests menstruation.
3. It elevates the uterus.
4. It shrinks the uterus.
5. It avoids the removal of uterine myoma.
6. It avoids vaginal hernia.

We have proved that the operation is suitable to every one of the above six propositions. Dr. Van Hoosen reports that not one of the cases in which I assisted her in operating has menstruated. I know of not a single case in which Dr. Waite and I operated where menstruation continued. We removed the appendages and tied the uterine arteries on a patient 37 years old, with a myoma extending above the pelvic brim. Three months later the tumor was decreased one-half; eight months later the uterus is what I should term almost normal in size. The operation shrinks the metritic uterus, which nearly always accompanies suppurating appendages. It shrinks the endometrium so that excessive secretions are checked. I have proved the shrinking or atrophying of the large, hard, metritic uterus, time after time, by subsequent examination. The operation elevates the retroverted uterus and maintains it in position. It is superior to hysterectomy, as it leaves a movable uterus.

Two months ago I operated with Dr. Verity, of Chicago, on a case with diseased appendages, and with a large, hard, retroverted metritic uterus. We removed the appendages and tied the uterine arteries almost down to the cervix. Eight weeks subsequent to the operation I examined the patient and the uterus was in distinctly normal position; it was movable and had shrunk at least one-third in size. Two objections might be raised against the operation:

1. The danger of gangrene.
2. The ligation of so much tissue.

I do not consider it an objection that one might penetrate the bladder with a ligature armed needle, or a ureter might be included in the ligature, as any other operation is encumbered with similar dangers. The idea that the ligatures might become infected and produce subsequent fistule, is not a serious objection. I would suggest that the ligature which includes the broad ligament should not include the Fallopian tube with its mucous membrane, as that might enhance the chances for suppuration. The needle could be passed just beneath the tube. This method ought not to protract the operation more than ten

minutes. In the thirty cases, one patient died from the results of the operation. The patient was a weak, worn-out woman of 37, who had a myomatous tumor for some six years. The broad ligament was tied in sections and the tumor shrank so rapidly in four days that it produced a kink in the bowel by dragging on it. The bowel was not completely obstructed. The patient went on well for four days, after which she suddenly sank in a few hours, without many symptoms. An autopsy revealed the fact that in four days the tumor had shrunk enormously, and a kink was found in the bowel. The debility of the patient and the worn-out nervous centers were to blame for this death. The other death among the thirty cases was due to urinary suppression on the sixth day in a woman who had almost flowed to death during six years with a large uterine myoma. The case progressed well for six days after the operation, when the urine ceased to be secreted and she died about thirty-six hours later.

## THE SURGICAL TREATMENT OF INJURIES OF THE HEAD.

TREPHINING FOR CLOT AND PRESSURE SYMPTOMS—NO FRACTURE.

BY R. E. HAUGHTON, M.D.

Formerly Professor of Surgical Pathology, Operative and Clinical Surgery, in Central College of Physicians and Surgeons Indianapolis;  
Member of American Medical Association, of Mississippi Valley Medical Association, of Texas State Medical Association, ex-President Indiana State Medical Association and Honorary Member Ohio State Medical Association.

MIDLAND, TEXAS.

In view of the great apparent progress in cranial surgery, in many forms of disease as microcephalus, idiocy, hydrocephalus, tumors, compression, clots of blood, cases where a transmutation of structure may take place, viz., hyperplasia of connective tissue, neuroglia of Virchow or glioma, I report a case to show what may be accomplished in the earlier stages of severe injury in aid of a final recovery. We must in some degree comprehend the structure and anatomy of the relations of the brain, how protected by its membranes, its bony case, its supply of blood within and without, the sources of blood supply internal and external; and comprehend the dilatation and contraction of the vessels under vasomotor influence, the reflex irritation upon vessels, the difference of cause in coma of compression and cause of irritation which may be reflex or direct, the relation of blood supply to connective tissue, before we are in any sense, in a condition to comprehend the many varieties of symptoms which present themselves, as in disease or injury, which progresses to very serious results. The result of experimentation upon the brains of mammalia with organizations much inferior to man, leave many questions as yet unanswered in regard to the human brain.

The diseases of motility, speech, sensibility and special sense all require a large comprehension of a very large number of pathologic facts which have been so far utilized in connection with the more recent developments in histology, so that to some extent a clinical summary is being reached which enables us in a measure to make out a clinical or surgical diagnosis with some degree of certainty.

Again, cerebral lesions are revealed by symptoms which when classified, enable us with some certainty to reach a diagnosis, for instance, we find a large

group of symptoms which are cerebral or cephalic, which are an entire departure from normal conditions and which, though beginning as to brain, produce disturbance of function of one-half of the body. Consciousness is in entire abeyance, and we have excitement, incoherence, delirium, or we have the opposite conditions of entire absence of brain power in any manifestations of intellect, or if any brain intelligence is manifest there is a complete abolition of motor power by which the senses operate externally. Paralysis of motion and sensation, especially on one side of the body, indicate physiologically, the crossing of fibers as they pass to the cord by way of the medulla oblongata, so that we begin to locate and classify symptoms. Irritation of motor functions, shown in stiffness, spasms or rigidity, clonic or choreic convulsions, with derangement of coördination or tremors of a limb of one-half of the body. The peculiar group of cerebral paralyses are less often produced by hyperemia or anemia of certain brain regions than by localized lesions of a sudden or acute character, viz., hemorrhage, serous effusion, inflammation and results, or hemorrhagic clot and compression because of a more or less widely diffused injury. In addition to these in immediate origin are the results of primary and secondary lesions causing arrest of motor or sensory impulses, because the paths or lines of transmission are injured, compressed or destroyed. The doctrine of localization of function has done much to clear up our ideas as to the relations of certain, local and definite functions residing in a special part of the brain, and thus following out the demonstrated relations of function we are enabled to clear up the diagnosis.

It is well recognized that the hemiplegic type of paralysis upon the opposite side to cerebral lesion is due to disease of motor centers as corpus striatum and lenticular nucleus, or to localized lesions of the cerebral lobes involving the peduncles and pons-varolii. The paralysis of one-half of the body appears in the muscles of the limbs, the extensors and the contraction of the antagonists. The muscles of the paralyzed side generally undergo no noteworthy change in electric sensibility.

This and much more might be said in reference to the varying conditions which may obtain in case of an injury which may be first, concussion, followed at once by symptoms of compression, which may and often does require surgical diagnosis and operative measures to relieve the compression, as in the case I am about to present:

*Case 1.*—Mr. W., a citizen of Midland and a cattle man, had gone out to his ranch to look after his cattle. He rode a horse which was not well broken, and for some reason, not known the animal reared and threw his rider, his head coming in contact with a pile of stone, which struck him about the superior margin of the left parietal bone near the parietal protuberance, producing a contusion of the scalp and also cut down to the bone. His skull was supposed to be fractured, by the physician who was called out to see him and he adhered to this opinion. On the second day Mr. W. was brought to Odessa and from there by train to Midland, a distance of about forty miles. During the time which elapsed from his injury, he was unconscious, paralyzed on the entire right side, stertorous respiration, pulse slow and labored, with difficult respiration at times and spasmodic action of the muscles of the same side as the injury, viz. left. Pupils dilated at first were afterward contracted. Functions of bladder and bowels arrested, except a stillicidium or dribbling from the bladder.

*Diagnosis or Summary.*—Concussion with compression of brain as shown by all the leading symptoms. Shock had been marked from the first, yet a sufficient reaction was secured to

move him as before mentioned, as no operative procedure could be instituted on the ranch. On Feb. 19, 1893, I was called into consultation with Drs. E. and C., just after night as he reached Midland, at nearly dark. The decision was reached that in an operation to determine whether there was fracture, a depressed fracture, it was necessary to elevate the bone, and relieve the pressure as it was a case of compression, though no fracture could be found. It was also determined by the consultation to operate for two reasons: 1, to determine as to the existence of a depressed fracture; 2, if this did not exist to trephine for the purpose of removal of a coagulum of blood, as it was assumed this also might exist from the nature of the injury, and as well from all the symptoms.

On the following morning February 20, we saw the case and proceeded to make an exploratory operation as to fracture, dissected up the scalp for the purpose and clearly demonstrated that no fracture existed. Then we at once proceeded to trephine at the point of contusion to find the cause of compression. We removed a small circle of bone, including both tables and upon its elevation the blood began to well up into the opening, very much as water wells up into a well when you reach it. The blood had not coagulated as it was occasioned by the rupture of divisions of the middle cerebral artery or parietal ascending branch. The dura-mater was carefully protected while using the trephine, hence the blood was from the artery, the middle "ascending parietal artery." There was a large amount of blood which was taken up by small sponges as it filled the opening. When this had been removed there seemed no clot in sight or on touch. The dura mater was intact so that we proceeded to close and dress the wound antiseptically. One suture was placed by a silver wire at the apex of the flaps and the wound had an antiseptic solution of peroxid of hydrogen and bichlorid of mercury in water, 1 to 2000 with light compress and bandage. The wound healed readily without suppuration, and the symptoms of compression slowly passed away. The patient after careful nursing, has recovered so he is working and transacting business, and was able to ride and walk in a few weeks after the operation. Since his recovery he went to Buffalo, New York, to the Surgical Institute to consult (as he believed) abler counsel than he could find on the plains. He came as he went, being informed that so far as surgery was concerned all had been done that could be done. I had an opportunity to determine his condition as he rode out in a buggy as soon as able, and one man who frequently took him out said to me: "He knows a fat steer and its value, and whether he owns it as quickly as he ever did, as I tested his capacity in that direction."

Some questions now arise as to the diagnosis, and in explanation of some if not all the principal facts in this case, it should be remarked here that we have had this year three cases of injury in the head, two of them recovering without any operative procedure, being only concussion of the brain. All of these cases were produced by falls from horses, two occurring in the night and the one here recorded in the day time.

The physiologic and pathologic fact existed of hemiplegia from the injury. This fact indicates, that compression of the fibers or cells of the left parietal convolution as they pass down into the medulla are transferred to the opposite side and (*vice versa*) when the injury is upon the other side. This was the principal fact which guided in this operation and which coincided with the second fact that the ("*pt-de-appui*") or site of injury was on the left, hence other things being equal we should find the compression under the injury.

Again, when we come to make up a diagnosis as to the clonic convulsive action of the same side of the injury, "the hemiplegic type of paralysis upon the side opposite to the cerebral lesion is due to disturbance of the motor ganglia, corpus striatum and lenticular nucleus, or it may be due to localized lesions of the cerebral lobes involving the peduncles and pons varolii."

Again, when hemiplegia occurs upon the same side as the cerebral lesion, a center is found in the motor

ganglia of the opposite side with alteration in the lobes of this side, and it may be with edema or pressure from blood in the parenchyma of the structure of the opposite side. We had a partial hemiplegia on the same side of the injury, but it was not persistent or permanent. This was accounted for from the fact that the concussion by a *contra coup* may have produced small foci of blood deposit and induced the condition of the side injured, or incomplete hemiplegia with startings or twitchings and spasmodic action of the muscles of the arm and leg of the injured side.

I have said the patient was trephined at Midland, and has slowly recovered, regaining such measure of power, intellectually and physically, as to walk about town with a cane yet with irregular, somewhat spasmodic action of the muscles of the limbs below, showing that he has not yet fully recovered the motor control of certain sets of muscles. I believe he will continue to improve in this direction until a fair use of the muscles may be regained.

Later, Jan. 1, 1895, he is still improving, and now superintending and building a large four-story hotel.

Surgical appreciation of methods and operations in traumatic and intra-cranial lesions without fracture. We have already come to a conclusion as to operative methods in cases of fracture, especially with depression of tables and clots of blood which may form in such cases, as in elevation of depressed bone and removal of loose or detached fragments. That is, relieve (*brain pressure*.) This leads us to another step. What shall be done with cases of intra-cranial lesions (traumatic) in which no fracture exists, as was clearly demonstrated in this case? Evidences of compression were clear, yet no fracture existed. What could cause compression? Two conditions clearly; effused blood which may be found beneath the injury of the surface, and points of effusion, (*ecchymosis punctatæ diffusa*) and, finally, fracture by *contra coup* might arise where lesion or force is sufficient. While cerebral localization may not and most probably will not always indicate the spot at which the cranium may be trephined, nevertheless in such a case as I have here described the demand is none the less as imperative as in cases of depressed fracture, as compression by extravasation of blood exists in both cases and in the first class of cases, bone is also depressed. What are the facts in cases where post-mortem examinations have been made?

1. Death occurs in all ages and conditions from such head injuries, without fracture of the skull, and the facts thus shown prove that a large per cent. of cases dying from brain fever and meningitis, especially in children, are the result of inflammatory action about a clot, producing abscess or softening due to some degeneration of injured cerebral tissue. Hence we may deduce a rule of action, that because these cases are not found accompanied by fracture there is certainly no good reason why they should not receive surgical attention, as they are amenable to treatment, as this case shows. Reports of cases, as I have gathered them up, show that the most grave cerebral lesions, manifested by very grave and serious symptoms, are produced without the slightest solution of continuity in the cranial structure and sometimes with no laceration or contusion of the scalp. Concussion of the brain, as a whole, may eventuate in a slow process of inflammation, softening or abscess and death some time after the injury

and when to all appearance the patient had seemingly recovered. I have a case now under observation who received a severe concussion, remaining unconscious for several days, but finally slowly recovering save a little unsteadiness of gait and excitability of manner. He was at first paralyzed in some of the muscles of the right side. No mark or contusion on the head or any part of the body.

The symptoms of pressure are induced by the effusion of the blood between the dura mater and skull as in this case, and which was fluid and not a clot, and the pressure symptoms were of a most severe and profound nature, hemiplegia of one side and partial of the other side, stertor, coma, depression and partial arrest of most of the vital functions, inability to swallow and many others, making up an entire aggregate of symptoms which threatened the life of the person.

Again, a rupture of a larger or smaller trunk or branch of the middle, meningeal or cerebral arteries would produce sudden and great compression and possible death, and yet there has been no fracture or injury external, but as in this case profound disturbance of all the nervous and vascular areas. What shall be done with such cases? Formerly they were bled, purged, blistered and tortured by an experimental medication till the patient was dead, or, with a vital force which would not succumb to the injury, aided by the bombardment of remedies got well in spite of disease and the doctors. The evidence of compression of cortical centers may be determined with some degree of certainty by a comparison of symptoms contrasted as here stated. I quote from the "Encyclopedic Index of Surgery."

## CONCUSSION.

1. Insensibility more or less complete.
2. Respiration feeble.
3. Pulse weak, irregular and frequent.
4. Special senses dull.
5. Pupils variable and sensitive to light.
6. Nausea as recovery goes on.
7. Bowels relaxed, sphincters not paralyzed.
8. Bladder can expel the contents.
9. Comes on instantly, but passes off slowly.

## COMPRESSION.

1. Total insensibility.
2. Respiration stertorous, slow, puffy.
3. Pulse slow, full, labored.
5. Pupils widely dilated or one dilated and the other contracted.
6. Stomach insensitve.
7. Sphincters paralyzed and bowels torpid.
8. Bladder paralyzed.
9. Does not appear at first but grows worse.

The two conditions usually coexist, but the compression is found to exist and hence concussion may pass into compression as the latter term means pressure, and paralysis is usually taken as a distinguishing mark—a diagnostic sign of compression. The cause of compression is here in such cases with no fracture a hemorrhage, and we should know where it is most likely to occur and the fact of compression make us cast about to determine the location of hemorrhage. If it is an injury done to the medulla, cerebral artery or its branches we can determine readily enough from the nature of the injury, as blood may be deposited between the cranium and dura mater, or if the latter is broken or injured, or if not so, sooner or later we have compression of the cortex and also we have pressure upon the ventricles and cerebro-spinal fluid and thus a general disturbance by pressure which must be relieved if possible. These conditions imply extravasation of blood within the cranium, contusion or laceration and these conditions are found upon the surface of the dura mater. In the cavity of the arachnoid, on the brain surface in the substance of the brain as by foci, or in the ventricles, especially the lateral and at the lenticular

nucleus. It may occur in the corpus striatum, thalamus opticus, and if in the cortical structure near the surface may, as the blood continues, force its way through the cerebral matter, uplift the pia mater or find its way into the cavity of the arachnoid. The most common location of hemorrhage is the corpus striatum and thalamus opticus in apoplexy, or from disease of vessels, and rarely in the white structure, viz., corpus callosum. Large amounts of blood will occasion tumefaction and softening of the cerebral mass and flattening of the convolutions of the hemisphere which is the seat of lesion; before an examination may be made it is suspected. Hence a rule of action now is to trephine promptly so that these graver lesions shall not have time to occur, as well as to remove the primary cause of trouble, the blood, whether it be a clot or fluid as pressure exists, and the patient has no power of continuance unless relief can be offered by a removal.

I shall not attempt to follow the blood and tissue changes as it would not be competent, but only to indicate the procedure and the promptness with which it should be done. The surgeon who fails to offer his patient the relief which such a procedure as trephining and removal of so much of cranial bone as may give relief to the pressure, and removal of the clot and fluid *débris* to the great relief of the existing pressure upon the brain, either has not comprehended what it is to take in the situation by a summary, or is too temporizing to be a safe surgeon. Suffice it to say that this case was operated upon Feb. 21, 1893, and is now and has been for a year or more walking around our streets in the transaction of his business, and while he does not walk as steadily as I do, yet he is far better than a dead man and gives promise by improvement that he may yet recover fully, due to the prompt use of the trephine or chisel in removal of blood pressure.

*The Technique of the Operation.*—The method to be pursued in microcephalus and in any condition of the brain requiring an operation is that it shall be done as quickly as possible to give sure and prompt relief to the compressed organ. In cases of injury without fracture but with sufficient evidence to require an operation to be made, the surgeon should resort to one of several methods in exposing the bone and dealing with the scalp. It may be a long U or rather a horse-shoe flap which has been preceded by a running stitch around the region of the flap beyond it, so as to control the bleeding from the scalp. The horse-shoe flap perhaps is preferable, yet if by any preference of education or otherwise, he may resort to the crucial incision, and expose the bone. The trephine may be used in one or more places, and then by cutting forceps cut away the interfering structure so as to gain room and relieve pressure. This should be done, cutting as much or as little as the special case in hand may demand.

It may be found in compression by blood or clot that the blood is found beneath the dura mater or external to it. Then the incision of the dura mater may require to be done to reach the blood, or if there is evidence that there is blood or pus beneath the surface of the dura or pia mater or within the arachnoid spaces, the pressure should be relieved. It may be difficult to determine some cases, yet ordinarily the diagnosis can be made and the operation should follow. In fact, I hold that it is imperatively demanded of the surgeon in the face of unconsciousness

or coma, with paralysis of one or both sides of the body, a slow and labored pulse and more or less difficulty of respiration, relaxation of the sphincters of the body, etc., to operate, and expect beside to benefit and probably save his patient. The technique should be great cleanliness and antiseptic precautions with as much protection to all the delicate structures as may be possible. Antiseptic gauze, iodoform, boracic acid solution (1 to 25 to 50) bichlorid mercury solution (1 to 3000 to 5000) or more, light bandage and compress after parts are externally adjusted. The patient may not be able to take anything until consciousness returns, then light unstimulating diet, quiet and rest in a room well ventilated at temperature of 70 degrees.

*Conditions.*—As a summary of propositions in such cases:

1. Cases of coma by compression, as distinguished from coma by irritation, which may be reflex or direct. We must decide a case, as one of compression, by some intercranial cause before an operation is surgically admissible.

2. That coma from reflex conditions and affecting vessels, and producing coma by irritation, or coma by contraction of vessels, and as a result vascular anemia, must be distinguished from the former.

3. There shall be no fracture in the cases herein considered.

4. We may have concussion and final compression of brain from rupture of vessels, accumulation of blood and pressure symptoms.

5. Given such conditions, what surgical procedure is required if any (except in second proposition), but found in first, second, third and fourth propositions.

Answer to these propositions: Operation—by necessity—except in proposition 2.

## THE SURGICAL TREATMENT OF INJURIES OF THE HEAD.

BY CHARLES B. PARKER, M.D., M.R.C.S., Eng.

CLEVELAND, OHIO.

The treatment of head injuries is a subject of general interest. Such injuries occur in the practice of every medical man. With the exception of such general remedies as rest, ice, cathartics and sedatives their treatment is necessarily surgical, and when successfully carried out furnish a good test of the mastery of the technique of aseptic and antiseptic methods.

No injury of the head can be considered trivial, for the simplest one may lead to fatal consequences. The cause of this results anatomically from the well-known close structural connection between the coverings and contents of the brain, and pathologically, in the fact of direct or embolic germ infection. Anatomically we have a rather thin skin connected to the aponeurosis of the occipito-frontalis muscle by a very dense cellular structure, the fibers of which have something of a ligamentous strength and inclose a peculiarly vascular adipose tissue with which the vessel's walls are intimately connected. The bone is not solid—an outer tough and an inner brittle table, and between, the vascular diploë; beneath these the dura mater. You know how intimately the dura is attached to the inner surface of the calvarium if you have ever attempted to remove it post-mortem. The dura mater is more dense than pericranium or periosteum; it is a fibro-serous membrane. You know

how delicate such membranes are, how easily injured and how easily inflamed. By this intimate structural and continuous vascular arrangement, the force of a blow directed at or nearly at right angles to a given surface of the head may be transmitted directly to this serous membrane, producing hemorrhage, with subsequent pressure and inflammatory symptoms. There is at least one anatomic provision to offset this, provided in the mobility of the scalp upon the pericranium, by which a force impinging upon the head at a tangent becomes a glancing blow and its full force is not transmitted to the brain.

Pathologically the rich vascular and lymphatic circulation supplied through the scalp, pericranium, diploë and dura offers a direct and complete highway for the entrance of infecting germs. When no wound can be made out we must regard the appearance of suppuration following head injuries as due to embolic infection.

We are, perhaps, all ready to acknowledge (from experience) that true acute suppurative inflammation and abscess formation is always the result of the action of germs, and that such inflammation does follow external injury to the skull, and yet at the same time we may be unable to fully appreciate the minute mechanism of its production and utterly unable to demonstrate the path pursued by the morbid agents, even when the inflamed territory or collection of pus is but an inch below and directly beneath the external scar. All this serves to show that it is often difficult and even impossible to predict the extent of the damage and the subsequent danger from the local manifestations of the injury. The symptoms alone are not sufficient. The former closely drawn differential signs between concussion and compression, are found untrustworthy, and we have learned that the question of infection or non-infection is a much more important one. But as a fracture opens up a possibly direct channel of infection, and at the same time may exert a disastrous pressure on the brain, its diagnosis becomes of prime importance. In certain extensive fractures with depression the diagnosis is easy. But in other cases again most difficult:

1. In cases without external wound. It was, I believe, the shrewd Irish surgeon, Abraham Colles, who said a fracture with a depression *always carries the scalp with it*, and that this furnishes the basis for a differential diagnosis between mere contusion of the scalp and fracture of the skull. This is the way he states it: "Run your finger along the scalp towards the tumor, and before it gets to its soft yielding center, your finger will have to raise over a ridge around its margin and then it will suddenly sink, which will not occur if it is really a depression in the bone."

If the bone is really depressed, you will find that the scalp is depressed along with it and there will be no tumor at all, and on running your finger over the place where you feel the depression in the scalp your finger will sink *gradually* into the depression." This observation will serve most useful purpose especially on the frontal and parietal bones, but in depressed fractures, otherwise located, cannot always be made out. Where any doubt exists in such a case, I believe it is proper for the surgeon to make an incision, observing all aseptic precautions, and thus determine beyond the shadow of a doubt the question of fracture or no fracture. I have never in but one case made this incision under such circumstances and found no fracture, and in that case the only effect of the incision

was to hasten the recovery by evacuating the bloody serous effusion, thus relieving the tension and promoting the healing.

2. In injury of the head, with wound, we also find great difficulty occasionally in determining absolutely the presence or absence of fracture. No one now uses the probe in such cases, as it is next to useless and may be dangerous. If any exploration through the wound is desirable after its thorough disinfection, the surgically clean finger can be used. But even then the fracture may be so placed that it can not be detected, as the following case in brief illustrates:

Tommie K., aged 11, was admitted to the Lakeside Hospital, having been struck on the back of the head by a passing freight train. There was a small punctured and lacerated wound just below and in a line with theinion. This was cleansed and carefully examined by the little finger but no fracture or even bare bone could be reached. Patient conscious, pupils dilated, pulse 40, respiration 12. Evidently there was some pressure or serious disturbance at base of the brain. Patient was anesthetized and a sharply curved incision carried out on either side from point of punctured wound for one and three-quarter inches. At the very base of this flap we came upon a V-shaped depressed fracture, base looking up and point buried in the membranes of the base of the brain. The moment the point was elevated the pulse jumped to 94 and the respiration to 26. In this case no suspicion of the fracture could be gained from any examination of the wound itself.

There is another reason why enlarging the wound by incision is useful, and that is the thorough cleansing of the wound. Dirt, hair and other impurities are often carried by the force of the blow beyond the touch or view. I make it an almost universal rule to enlarge the incision, especially in the smaller and punctured wounds of the scalp, and am nearly always rewarded by finding some dirt which could not otherwise be reached, and occasionally a fracture which had not been suspected. This little procedure rarely requires an anesthetic, as the parts are already bruised and numbed.

In compound depressed fractures of the skull, proceeding as above outlined, I am in the habit of using the chisel rather than the trephine to effect the elevation of the depressed bone. With the chisel it is often only necessary to remove a narrow overhanging shelf of bone from the outer table, or to cut through the serrated edge where the depressed bone bends away from the uninjured portion of the skull. The objection that the blows of the hammer add to the already existing concussion does not hold good, for with a properly constructed chisel with a sharply concave or sharp V-shaped cutting edge and a thick handle, such as is found in a shoemaker's awl, the operation may be made entirely by the hand. The chisel saves so much bone, may be operated so much more quickly, and it is next to impossible, unless grossly careless, to injure the dura mater. I have spoken of saving the bone fragments. The following case, in brief, will illustrate my practice:

A little fellow, 5 years of age, while playing, fell from a box car and struck on the iron drawbar of a switch. When he reached the hospital considerable brain matter was found matted in his hair. The whole right side of his head was smashed and flattened, and a fracture extending into the frontal bone in front to the occipital bone behind. He was conscious and promised to be a good boy if I would let him sit up and look out on the lake. He was anesthetized, a large flap raised and the extensive depression exposed. There was a large central oval piece of bone its greatest diameter, perhaps, a little less than three inches, its lesser a little more than two inches and surrounded by a number of small, irregular depressed pieces. By means of a chisel

these smaller fragments were loosened and removed. The large central fragment immediately came into position. It was perfectly loose and bare of both pericranium and dura, and a severe hemorrhage from the middle meningeal and some of the large branches of the middle cerebral occurred. The fragment of bone was raised and a long strip of iodoform gauze packed over the bleeding surface, the end of the gauze being left out at the lower margin of incision for drainage, and the piece of bone returned to its place. Gauze drainage removed at end of thirty-six hours. Wound was re-dressed on fifth day and again on the tenth. At first dressing the fragment of bone showed very white through the bruised wound, but at second dressing it was completely covered by granulations, and recovery took place with some paralysis of motion in the left side.

This is not the only experience I have had in leaving the larger fragments of a depressed fracture in place, and thus far have had no occasion in depressed fractures to insert a sheet of sterilized gold foil or platinum plates to prevent cerebral hernia. I can readily see that it might be of advantage after trephining, especially for epilepsy, to insert some non-irritating substance in the buttonhole to prevent any union between the dura and pericranium. But in nearly every case in which some such method has been attempted, so far as I can learn, though for the time being successful, sooner or later suppuration has occurred with sinus formation which necessitated the removal of the foreign substance.

As a preventive against cerebral hernia, I believe nothing to be of such value as an aseptic wound, and when infectious suppuration has taken place nothing will certainly avert this most distressing and most fatal complication of head injuries.

We may sum up our conclusions as follows:

1. In any case of doubt as to the character of a head injury, to explore by incision if necessary.
2. In the case of wounds, especially the smaller and punctured, to enlarge them for exploration and cleansing.
3. In all cases of fracture, depressed or fissured, to operate, elevating the depression and exploring the fissure for a depression of the inner table, which so often does occur.
4. To leave principal fragments of bone after elevation, if surgically clean, even if entirely detached from the dura mater and pericranium, thus averting cerebral hernia, vertigo and other cerebral disturbances.
5. That all these operative measures should be conducted under the most rigid aseptic and antiseptic measures.

### THE SANITARY CARE OF SMALLPOX AT COOK COUNTY HOSPITAL DURING THE LATE EPIDEMIC.

Read before the Public Health Section of the Chicago Civic Federation.

BY RICHARD BARTLETT OLESON, M.D.

CHICAGO.

Theoretically, smallpox is not treated at the County Hospital. But during the epidemic which existed last winter it became necessary, as a matter of humanity, to provide for the 400 victims of the disease who sought medical aid there. From a sanitary point of view, these were easily separated into two classes; those who only required a place of shelter until they could be sent to the smallpox hospital, and those who were too sick to be moved, needing nursing and medical care.

Early in the epidemic it became very evident that the facilities at the disposal of the City Board of

Health for handling smallpox patients were, to put it mildly, extremely inadequate. As soon as we began to receive patients in any great number we saw that it would be impossible for us to depend on the chance of getting a smallpox ambulance to take them to the special hospital, and so, through the courtesy of the Warden and the Hospital Committee of the County Board, one of the County Hospital ambulances was diverted from its legitimate work and set to conveying smallpox patients from the County Hospital to the pest house. As soon as we got enough patients we made up a load and sent them on. So the ambulance trips were irregular. One patient would simply step into the wagon at once; another might be kept for forty-eight hours. Hence you will see that the hygienic care of the different patients varied greatly.

The way in which we handled an ordinary uncomplicated case that we intended to keep for some time was as follows: All persons seeking admission to the hospital must pass the doorkeepers who soon became quite expert in detaining suspicious cases. At such times the examining physician was at once called, and if he pronounced the case to be variola the man did not enter the hospital building proper, but was taken by an orderly around to the entrance of the contagious disease ward, which can only be reached from the outside. The ward itself is on the fourth floor of the new pavilion and is entirely isolated from the rest of the hospital. In this ward, which is made up of detached rooms, a large apartment with its own special closets and toilet rooms was set apart for the reception of these cases, and here a male nurse dwelt constantly.

Upon admission, patients were given an ordinary scrub bath with soap and water and put to bed, upon a new clean mattress with new bedding, unless they were merely to wait for the ambulance and it was reasonably certain that this would depart soon. In this case, nothing whatever was done to them. The clothes of the bed patients were placed in a corner of the room until they could be fumigated. If it became possible to send a patient to the pest house before fumigation began, he went in his own clothes; otherwise a new suit of hospital clothes was given him. Then he was put into the ambulance, with a certificate from the house physician to the effect that he was a proper case for the smallpox hospital. Then, if he had occupied a bed, the bedding was taken by a special porter out into the large open lot behind the contagious disease ward, and there burned; and we considered our connection with that particular case to be ended.

Owing to the fact, as at first stated, that the hospital did not intend to care for variolous patients, there was no modern fumigating furnace. We improvised a substitute by placing the clothes in a small windowless closet containing a steam coil. The end plug of that coil was taken out, and an iron kettle of one gallon capacity, placed on bricks to elevate it from the floor, was filled with brimstone and alcohol, and the alcohol fired. Then we shut the door, pasted up all the chinks and crannies, turned on the steam from outside and left it for two days. Then we turned off the steam and as soon as we thought the room was cool enough we opened it, raked out the clothes, and put them in a clean closet to await orders.

When a patient who had passed through the disease in the ward completely recovered (and we considered

this point to have been reached when none of the pustular eschars could be found on him), he was given a thorough tub bath in a small bath room just off the ward, ordinary soap and water being used. The tub was then cleaned and the patient bathed in a 1 to 1000 solution of bichlorid, after which a third bath of clear water without soap was given. Then the sites of the eruption were sponged with alcohol (care being taken to protect the eyes) and he was wrapped in a clean old sheet, in which he walked out of the ward to another room. Here the sheet was discarded, his fumigated clothes given him and he was allowed to go free. Then all his bedding, with the last clean sheet just mentioned, was burned, and his bed fitted up fresh for the next case.

Many of the seriously ill died in the ward. When this occurred their bodies were wrapped in a winding sheet soaked in 5 per cent. carbolic solution (the body having first been bathed in the same solution), and a second sheet saturated with 1 to 500 bichlorid placed outside the first. Then the body was placed in a pine coffin, this in a zinc-lined box, the top close fitting, was screwed down tight and the body sent to the cemetery. All his belongings not of value were then burned. Coins, chains, etc., were boiled.

No attending physician visited the smallpox ward. The house physician (who, by a somewhat unfortunate arrangement, had at the same time to attend the measles, diphtheria, scarlet fever and erysipelas wards) on entering the ward assumed a jacket and apron over a special suit of clothes. On leaving, he doffed the jacket and apron, removed his outer garments, and then sterilized his hands before donning the clothes he wore in the other wards.

In conclusion, the writer wishes to take this opportunity of stating that the then Warden of the County Hospital, Mr. W. T. Monroe, deserves the sincere thanks of every citizen of Cook County for the prompt and efficient aid he lent to every effort made for the stamping out of the pest. The house staff put redoubled zeal into their work with the knowledge that the Warden could be depended upon to back them in all their undertakings.

## ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

### HISTORY OF CASE. REMARKS.

Jas. Crawford, aged 8 years, taken ill Aug. 16. Saw him for first time on evening of Aug. 16. Crawford children had arrived from Ireland only three months previously. In this case, as soon as remission and exacerbation began to be distinctly marked (say from about the seventh day), I began using quinia in gr. xx doses in 24 hours. The remission and exacerbation evidently were not affected by the drug for several days, and then variations continued for some time after Aug. 23, when, owing to an accident, I was compelled to suspend the use of the thermometer. I gave quinia from the morning of the twelfth day. The condition of the stomach remained good nearly all the time. I gave beef tea and milk several times each day. In this, although the symptoms and appearance of the patient pointed strongly to yellow fever, and although the urine contained albumen, still the indications afforded by the pulse and thermometer caused hesitation. Quinia, however, although freely used, did not bring about any solution to my doubts, and I finally suspended its use. The fever really seemed to decrease after the twelfth day, and the minimum of pulsations (40) was reached only at the close of the eighteenth day. For several days during the height of the disease, I was considerably annoyed by a free discharge of blood from the gums, which was at last checked by the internal use of the perchlorid of iron. Convalescence was tedious, owing to the great debility of the child, who suffered from several carbuncles attended by sloughing.

### REMARKS.

Father Schneider; taken ill September 20, about 2 P.M.; died on September 23, at 9 A.M. Black vomit. Had spent two years in St. Thomas; came to New Orleans March, 1870. Immediately after his death the bed and bedding and his clothes were burnt; the room and house disinfected a few hours later by the board of health.

Joseph Fitzpatrick, aged 6 years; taken sick September 21. Had spent more than one summer in the city. Recovered. September 21, pulse, morning, 156, evening, 148; Sept. 22, morning, 128, evening, 120; Sept. 23, morning, 108, evening, 104.

### CHAPTER V.

#### POST-MORTEM TEMPERATURE IN YELLOW FEVER.

The medical profession is indebted to Dr. Bennet Dowler, of New Orleans, for the first, and up to the present time the most extensive, observations illustrating the temperature of various portions of the body after death from yellow fever.

The results of the researches of Dr. Dowler were

originally transmitted to the *Western Journal of Medicine and Surgery*, during the winter of 1843-44, but were returned to the author unpublished. The original data were published sixteen years later by Dr. Dowler in the *New Orleans Medical and Surgical Journal*, March, 1860, Vol. xvii, No. 2, pp. 199-220, and from this paper I have consolidated the following tables, which will illustrate the state of our knowledge with reference to the post-mortem temperature in yellow fever:

Temperature of the primary period of those who died of yellow fever.

Hours Sick.	Hand.	Axilla.	Observations.
12	102°	105°	Died in seven days. Died in four days.
12	103°	107°	
12½	105°	105°	
24	104°	107°	
28	107°	107°	
15	102°	102°	
37	97°	102°	
26	104°	109°	
29	107°	108°	
31	103°	104°	
42	97°	102°	Died in two days.
24	99°	100°	
24.6	102.5	101.9	

Temperature of middle period of those who died of yellow fever.

Hours Sick.	Hand.	Axilla.	Observations.
1	99.5°	104 °	Died in three days. Died in four days. Died in three days. Died in three days.
5	101 °	104 °	
5	97 °	102 °	
3½	100 °	105 °	
3½	100 °	105 °	
2	100 °	102 °	
4	104 °	107 °	
3	100 °	104 °	
4	102 °	105 °	
5	91 °	102 °	
6	100 °	105 °	A relapse. Died in four days. Died in three days.
6	102 °	105 °	
7	98 °	100 °	
8	93 °	99 °	
5	99 °	104 °	
8	102 °	102 °	
12	106½°	105 °	
1	99 °	100 °	
6	100 °	104 °	
7	91 °	102 °	
7	101 °	104 °	Died in two days. Died in three days.
8	102 °	102 °	
12	105 °	106½°	
14	101½°	103 °	
6	99 °	103 °	
6.4	99.4	103.39	

Temperature in the primary period of yellow fever in persons who recovered.

Age.	Hours Sick.	Hand.	Axilla.	Observations.
29	31½	102°	106 °	V. s. ad del.; cured in six days.
28	20	102	105	V. s. ad del.; well in six days.
24	8	101	103	V. s. ad del.; well in seven days.
30	9	100	106½	Cured in thirty-eight days.
5	102	104		Intermittent type; well in eight days.
30	12	105	105	V. s. ad del.; cured in six days.
35	13	102	104	Cured in seven days.
24	14	102	104	Cured in ten days.
27	13½	102	104	Cured in twenty days.
21	16	107	107	Cured in seven days.
28	19	102	104	Cured in three days.
29	22	102	104	V. s. ad del.; well in four days.
25	28	102	106	Cured in nine days.
28	26½	102	104	V. s. ad del.; cured in fourteen days.
41	48	99	102	V. s. ad del.; cured in one day.
30	48	98	104	
22	48	104	106	
21	48	102		Ninth day convalescent.
28	48	97	103	Ninth day cured.
26	48	105		Cured in ten days.
29	48	97	102	Cured in six days.
23	60	103		Cured in seven days.
34	24	99	102	
31	14	95	102	Cured in twenty days.
25.5	26.8	101.2°	104.1°	

Temperature in the fatal stage of yellow fever, with some account of the respiratory action.

Hours before Death.	Hand.	Axilla.	Respiration.
10	101 °	102 °	Respiration quick and uneasy.
24	95	104	Respiration quick.
8	101	101	Coma; seven respirations per minute.
1	91	100	Respiration tired, heaving.
1½	94	100	Respiration noisy, quick, laborious.
6	89	100	Respiration noisy, slow.
2¼	70	95	
9	94	100	Respiration imperfect, quick, irregular.
21¼	95	100	Respiration noisy.
21½	104	106	Respiration irregular.
11½	81	90	
11	88	100	Respiration quick, wheezing; coma.
10	84	95	Respiration easy.
7½	86	97	Respiration laborious, irregular.
12	95	102	Stertor; coma.
11	89	95	Respiration quick and irregular.
12	99		Respiration noisy, quick and laborious.
6	83		Respiration imperfect, small, irregular, quiet.
7	81	90	Respiration extremely laborious, gasping.
26½	104	105	Coma; stertor.
24		100	Respiration hurried; coma.
21½	97	104	Coma; stertor.
23	89	98	Respiration quick.
1	84	95	Respiration slow; loud heaving.
67½	101½	103	Respiration imperfect.
5¼	100	101	Respiration quick and irregular.
12	102	102	Respiration quick.
40		97	Respiration quick.
24	89	100	Respiration loud, laborious, rattling; coma.
1		102	Respiration loud, puffing.
2		100	Respiration loud, quick; coma.
48	88½	97½	Respiration quiet, puerile.
2½	89	99	Respiration stertorous; coma.
24	93	97	Respiration hurried, unequal.
28	102	104	Respiration easy.
72	88	101	Respiration quick, very easy.
5		95	Respiration rapid, small.
9		98	Respiration hurried, suffocative.
4½	89	97	Respiration easy.
24	91	101	Respiration imperfect; nineteen per minute.
24	88½	102	Respiration wheezing, puffing; rattling cough.
2	93	97	Respiration irregular, laborious, quick.
24	66	95	Respiration quick, puerile.
12	93	101	Respiration quick, puerile, loud.
12		100	Respiration hurried.
30	104	106½	Respiration hurried.
4	102	104	
6		96	Respiration slow, imperfect.
12	100	101	Respiration fifty-seven; coma.
24	100	103	Respiration stertorous; comatose.
5	89	100	Respiration noisy, slow.
16.6	92.2	99.5	

Temperature of the middle period of yellow fever of those who recovered.

Age.	Days Sick.	Hand.	Axilla.	Observations.
30	6	106 °	108.2°	Third day convalescent.
27	2	102	105

cially of the nervous system is of great practical importance. I have admitted for the sake of argument, that all syphilitics do not present early toxin neuroses. I will now proceed to contradict this assertion. Every syphilitic in my estimation, suffers from toxin neuroses, but as suggested in the early part of my paper the routine neuroses are not recognized as such.

One of the early phenomena of syphilis is the so-called syphilitic fever. This condition consists of an *ensemble* of symptoms of which a high temperature is by no means the most prominent feature. Headache, malaise, neuralgic and rheumatic symptoms occur, and in some cases prove quite troublesome. These various phenomena and indeed, the fever itself, I believe to be due to the action of the toxins upon the sympathetic system, and upon peripheral and central nerve structure. Perverted metabolism from the intoxication of the sympathetic may explain the fever quite satisfactorily. It is to be noted in this connection that not all cases develop this fever. When it does occur, I believe it to be due to nervous instability—so-called idiosyncrasy in this instance. This idiosyncrasy is similar to that which produces untoward effects of drugs, the toxins of shell fish, over-ripe tomatoes, etc. Carrying the argument a little farther, we have an explanation of the initial eruption of secondary syphilis—the roseola. Unlike all other lesions of the skin and mucous membranes, this form does not present in its macules an accumulation of syphilized germinal cells, but a simple vascular change involving vaso-dilation, stagnation and disorganization of the red corpuscles with a liberation of their pigment.

The lesion is non-destructive, and more or less transitory, leaving in its train a coppery or brownish red stain. This roseola is most logically explained by an aberration of vasomotor impulse due to the action of the syphilitic toxins upon the sympathetic. Analogical reasoning is not always satisfactory, but in this instance the analogy furnished by the untoward effects of drug and other toxin eruptions appeal to our sense of clinical discrimination most strongly. Apropos of other toxin eruptions, I desire to call attention to the form that sometimes appears in diphtheria—not the scarlatinoid, in which a mistake in diagnosis or even a mixed infection are possible, but that later type which heralds approaching dissolution. Here, we often have a very fair imitation of the syphilitic roseola.

Another lesion of early syphilis which appeals to me as a neurosis—trophic if you please—is the alopecia. I fully realize that I am treading on dangerous ground; the close association of alopecia with tangible cell deposit in other situations has led to the tacit acceptance of this lesion as an evidence of the action of the *materies morbi* of syphilis *in loco*. Some authorities believe it to be due to local empoisonment of the hair follicle with resultant nutritive perversion. Otis, following Bäumler, and Besiadecki, thinks that alopecia syphilitica is due to pressure innutrition of the hair follicles produced by an accumulation of syphilized cell material. I myself long taught this view. A moment's reflection should convince one of its fallacy. The following considerations are important in this connection:

1. Lesions of the scalp of sufficient prominence to attract attention are rather exceptional in syphilitic alopecia, a few scattered papules and accumulations of epidermal cells or sebum being found in a certain proportion of cases.

2. Scarring is rare and when it does occur, permanent baldness of the affected area results as a rule.

3. Tertiary syphilis in which cell accumulation is most marked is rarely causative of characteristic alopecia.

4. Severe alopecia, not only areate but generalized, may occur without any other lesion. This could hardly occur if the alopecia were due to cell deposit, inasmuch as in the early secondary period when alopecia is most often found the tendency to cell deposit is quite generalized.

Reasoning by analogy, we find much support for the neurotic theory of alopecia. The effects of fright, fevers and head neuralgias on the color and nutrition of the hair are well known. Leloir, Dumesnil and others have cited cases where traumatism of the sympathetic has produced alopecia. Joseph's experiments are quite significant in this connection. He divided the spinal ganglion of the second cervical nerve in cats and thereby produced baldness.

Accepting as I do, the nervous character of the syphilitic roseola and alopecia, these lesions are to me very suggestive. If they are due to disturbance of the sympathetic we have only to imagine similar vasomotor and tropho-neurotic changes in the central and peripheral nervous system, to get a tolerably clear idea of more serious neuroses in early syphilis.

To sum up the question of toxins in early syphilis, I believe that they bear a most important relation to the cephalalgias, neuralgias, bone pains, myalgias, paralyses, and rare cases of mental disturbance found in early syphilis, which affections for the most part are an evidence of the action of the toxins on the nervous system, and especially upon the sympathetic. These disturbances are often transitory, independently of treatment but they leave behind them a vulnerability of nerve tissue which may determine much more serious trouble later on. Precisely how the toxins act we do not know—we are as ignorant here as in the case of many other organic poisons. That vascular changes bordering on inflammation of nerve structure and its envelopes occur in some cases is probable enough, but is difficult of proof. The earlier the disturbance the less likely it is to be due to organic cell deposit.

In concluding what I have to say regarding the relation of the toxins to syphilitic nerve and brain disease, I desire to call attention to one point involved in the views of our distinguished Fellow, Dr. Bannister, to which I beg leave to take exception. I believe firmly that he is correct in his position regarding the syphilo-toxic origin of some cases of general paresis, but I do not believe that the toxin remains latent in the system for a prolonged period. He does not believe that the toxins prepare the way for paresis, but that they exist and are operative at the time the paresis begins. With the cessation of bacterial evolution, I believe that the toxins are eliminated—I do not believe they are stored up for future morbid action. Bacterial evolution probably ceases with the cessation of the active period long before general paresis develops. Cerebral syphilo-toxemia possibly does pave the way for paresis, but it probably does so by profoundly perverting the bio-chemistry and possibly in a minor degree, the structure of the cerebral tissues. This impression produces no very disastrous results in the early history of the case; but later on, as nutrition becomes relatively impaired by advancing age and directly impaired by intervening

pathogenetic factors, serious trouble results. It is a fact well known in pathology, that early damage to tissue may not reveal itself for many years—this aside from disease due to germ infection. This is even true of some cases of malignant disease.

In studying the nervous phenomena inferentially due to cell infiltration in early syphilis, it is to be understood that it is difficult to differentiate them from the toxin variety. The later the development of the phenomena, the greater the probability of the existence of definite organic lesions. In late secondary and tertiary lesions these may be well marked. In a general way, the toxin neuroses have their point of departure during the first three or four months of syphilis, the later varieties being of neoplastic origin. The younger and more active the germ the more virulent and abundant its toxins. In the true tertiary period the syphilitic germ and its toxins are probably no longer a factor in syphilitic neuropathology, save as respects the tissue vulnerability and morbid cell impulse already described.

The exceptions to the general rule regarding the dependence of the very early nerve disturbances upon toxins are chiefly cases in which hemiplegia or some severe form of paralysis develops; in hemiplegia especially, the inference that a localized cell accumulation exists is usually justifiable.

Organic or functional nervous disturbance is produced by syphilitic new growth in numerous ways, viz:

1. By invading the lymphatics surrounding nervous structure.
2. By involving the tissues, chiefly the lymphatic vessels, surrounding the blood vessels supplying or draining the part.
3. By invading the arterial walls.
4. By infiltration of connective and other tissues about nervous structures.
5. By involvement of the nerve or brain tissue proper.
6. By involving nerve sheaths or the cerebro-spinal meninges.

These various conditions act by producing:

1. Irritation.
2. Pressure innutrition, and occasionally degeneration.
3. Passive hyperemia and edema from venous obstruction.
4. Localized anemia (ischemia) from arterial obstruction.
5. Blocking up of the affected area by lymphatic obstruction.

It is rare that extensive destruction of tissue from breaking down of the neoplasm occurs in the earlier nervous lesions. It is to be remembered, however, that gumma at an early period may develop from the intrinsic malignancy of the disease.

The predilection of syphilitic cell growth for lymphatic glands and capillaries is well known; most of the neoplasia of syphilis are essentially processes of lymphatic infiltration and obstruction. This is not only true of the active but also of the sequelar or gummy period. In the latter, however, the process is largely one of lymphatic obstruction and congestion, while in the former, essential infiltration of lymphatic structures exists. The difference between the two may possibly be explained by the hypothesis that the gummata are chiefly due to old-time injury of lymphatic tissue by the essential infiltrations of this tissue incidental to the active period.

Vascular involvement—direct or by the pressure of syphilitic cell growth—is probably the most important factor in the etiology of organic nervous disease in early syphilis; as already remarked, however, the more remote the period after the chancre, the more likely is the process to be due to arterial disease.

The apparent predilection of the syphilitic process for arteries of medium size, and especially those of the brain is well understood, but has not been satisfactorily explained. A brief consideration of a special anatomic point—which still further emphasizes the importance of lymphatic pathology in syphilis—makes this circumstance fairly intelligible.

The peri-vascular lymph spaces are an integral element of the lymphatic system, and share in its special susceptibility to syphilitic involvement. Pressure upon and inelasticity of small or medium sized arteries, quite seriously disturb nutrition of the supplied area, with consequent aberration of function in the latter. This is a very important matter as regards the brain. The perivascular spaces of the large trunks are involved it is true, but the resultant pressure and inelasticity are a trivial matter in comparison with the resisting power of the large arterial tubes and the relative quantity of fluid forced through them.

Another vital point is this; the tunica adventitia of the vessels is probably a part of the lymphatic system; it certainly is extensively involved in early syphilis. Hutchinson seems to believe that the tunica intima is primarily involved, the adventitia sometimes and the middle coat only secondarily, but despite so weighty an opinion, the author inclines to the view that the point of departure is the adventitia. Apparent evidence to the contrary probably depends upon the fact that most of the cases studied have been late cases.

Hutchinson says that syphilitic arteritis does not produce aneurysm. This is true as regards the early stages, but the endarteritis of late syphilis is a most prolific cause of those miliary aneurysms which bear so important a relation to cerebral disease, especially of the apoplectic variety.

With reference to Mr. Hutchinson's opinions of vasculo-cerebral syphilis, it is a peculiar fact that some of the cases which he records are directly opposed to his own views regarding the point of departure of the pathologic process. He quotes a case reported by Sharkey in the transactions of the Pathological Society of London, of a man who died of vasculo-cerebral disease in the seventh month of syphilis, while still covered with a secondary eruption. The disease was symmetrical, affecting both middle cerebrals. "*The process had begun in the tunica adventitia and had spread inward.*"<sup>1</sup> Both arteries were occluded, the right completely so, and the areas supplied by them were softened. The patient had suffered from headache and was under treatment for syphilis when he had suddenly passed into a semi-comatose condition, with convulsions of the extremities; in this state he remained until his death one week later. Another case which he quotes, is from Dr. Clifford Allbutt, of Leeds. The age of this patient's syphilis is not given. In the brain were found scattered masses of syphilitic neoplasm involving the smaller arteries; these varied from the size of a pea to a walnut and were somewhat indurated. *Micro-*

<sup>1</sup> Italics mine.

*scopic examination showed that the process began with cell exudation and proliferation in the perivascular canals, finally causing great perivascular thickening."*<sup>2</sup>

The Fellows of the Academy will please note the support afforded by these cases to the views which I have expressed regarding the relation of the tunica adventitia and the perivascular lymph spaces to the initial arterial lesions of syphilis. It would appear that Hutchinson has formed his conclusions mainly from cases of late syphilis in which the point of arterial departure is often lost in the extensive gummy changes and secondary degenerations of this period. The earlier vascular changes which are really at the bottom of the difficulty have usually disappeared, the latter changes which replace them being given credit for the entire field of pathologic change. In the presence of large diffused gummata, with or without degeneration of the inner tunic of the vessels, it is by no means surprising that the earlier changes are masked, underestimated or entirely overlooked, even though they have not completely disappeared, as I believe they are most likely to do. Early perivascular exudate especially, may produce most disastrous effects on vascular wall nutrition and yet be removed in due time. Its presence in tertiary cerebral syphilis would be conclusive; its absence, however, argues little. It is probable that the arterial changes of early syphilis are chiefly operative in the production of ischemia of the brain and nerve tissue, with resultant loss of function. Vicarious hyperemia from obstruction of certain areas and compensatory pressure in others, supplied by sound vascular twigs from the same vessel, is a possible element. Passive congestion and edema from venous involvement are additional possible factors. Hutchinson has called attention to a peculiar form of phlebitis due to syphilis; this may occur in the brain.

It is not beyond the bounds of logic to assert that all of the conditions described may possibly co-exist and that intoxication by syphilitic toxins may be superadded.

Hemorrhages, distinct tumors, embolism, thrombosis, vascular ulcerations—softening of the tunica intima—are not to be expected in this early stage. Intra-cranial nodes, while possible, are certainly rare at this time. Meningeal infiltrations probably occur, but as a rule do not appear to excite symptoms. Such damage as may be done early in the disease manifests itself by symptoms at a relatively much later period.

It is obvious from what has been said, that the changes mentioned as characteristic of syphilitic cell deposit, are much more likely to be localized than those due to a universally circulating toxin. It is to be remembered, however, that the toxin may cause symptoms referable to a particular area of nervous distribution, by producing aberrations of vasomotor impulse through its action on the sympathetic. Involvement of nerve and brain tissue has been mentioned as occurring in very early syphilis, but it must be very rare. Such invasion as does occur must be slight, and acts merely by laying the foundation for later gummy disease. It will be understood in this connection, that I do not deny the possibility of precocious gummata of the brain. In such cases, however, there are abundant extra cranial evidences of malignancy. In a general way it will be found that large circumscribed gummata are characteristic of the tertiary period, while those of the earlier period are

not only small but disseminate. The disseminated lesions of early involvement of the choroid, fairly illustrate what may be expected in the brain in early syphilis.

(To be continued.)

## SOCIETY PROCEEDINGS.

### Associated Health Authorities of Pennsylvania.

*Second Annual Meeting held at Harrisburg, Jan. 30, 1895.*

MAJOR M. VEALE, First Vice-President, Health Officer of Philadelphia, presided.

Gov. D. H. HASTINGS, ex-officio President, was presented with a handsome gavel by Dr. B. Lee in behalf of the State Board of Health.

SECRETARY ATKINSON, in the absence of Dr. C. McIntire, read his paper on

#### THE SANITARY TREATMENT OF COMMUNICABLE DISEASES.

A communicable disease is one able to be communicated from one person to another, either by direct contact or through food or drink. The sanitary treatment is the means adapted to prevent this. Our methods depend upon the hypothesis we adopt. Thus cholera flourished in spite of our efforts, till we learned that it was a waterborne disease; then our efforts succeeded. Many diseases are known to be associated with a pathogenic microbe, the method of conveyance differing with different diseases. When a disease is to be combated, the Health Officer adds materially to the expense, etc. Hence in our sanitary treatment we should impose no unnecessary burden. We should live up to the knowledge we have; thus in typhoid, as we are reasonably sure that it is not carried by the air, but by the person becoming soiled by the alvine discharges from the patient, there is no need to include this disease among those where special precautions are to be taken for transportation upon railways, etc. Cerebro-spinal meningitis does not seem any more communicable than pneumonia; then why should physicians be compelled to report it? We should frankly acknowledge our limited knowledge, and where the case involves unsolved problems, our precautions should include an attempt to protect against every plausible method of communication. We should ever be on the alert to learn new facts, and modify our treatment accordingly. The Health Officer should be a physician, not a policeman. The municipality should be willing to pay as much to him as to its attorney or surveyor. Without this a self-respecting physician should decline the position. On these foundations, I will outline the treatment. Diphtheria will be a good illustration. Compulsory notification should be insisted on. If in doubt as in chickenpox, it should be reported. In diphtheria, not only pseudo-membranous croup but diphtheritic sore throat should be reported. With proper care, no harm will result, lives may be saved and a source of temptation removed from the physician who may desire to save the patient from the surveillance of the Health Officer. This person visits the house as soon as possible, and in diphtheria separates the sick and the attendants from the well, if necessary sending them to a hospital. Next he inoculates as many prepared tubes as he may require with the secretions of the throat of every one, quarantines the house till the bacteriologist reports, say twenty-four hours. If needed, suggests to the attending physician the use of antiseptic sprays to the air passages of the apparently well. It is not wise for him to suggest any treatment for the sick. He directs isolation. In diphtheria two rooms are enough; one for the patient, one in which the attendants change clothing before mingling with others. The nurse is to be instructed in disinfecting the discharges, especially from the throat and nose. Restriction depends upon the intelligence and willingness of the family. When the bacteriologist reports, raise the quarantine from those free from the microbe. If the isolation has been observed, and throats sprayed, the chance for infection has been slight. If others

<sup>2</sup> Italics mine.

show presence of the microbe, isolate at once and refer to the physician. Placard the house at first visit. The Health Officer should next visit the school or work shop of the patient, and inoculate tubes from the throats of every one in the room. Further precautions will depend upon the result from these tubes. All articles capable of disinfection should be so treated. When recovery occurs, continue isolation till the throat is free of bacilli; no other time will be safe. If death occurs no public funeral should be permitted. Dr. Geo. Duffield's "prophylaxis" is bacteriologic diagnosis; quarantine of quarters; isolation absolute with one nurse; better disinfection under the charge of the Health Officer; notifying pastors of churches and superintendents of Sunday schools of the disease and its locality; the establishment of the overflow drinking cup in all our schools.

MAJOR VEALE emphatically indorsed the points in the paper, and quoted largely from his experience with the city of Philadelphia.

MR. CROSBY GRAY, of the Department of Public Health read a paper on the

#### LEGISLATIVE RESTRICTION OF COMMUNICABLE DISEASES.

He indorsed the whole of the paper of Dr. McIntire. The foundation for this treatment is law; education will not suffice. The health authorities must be notified early. Unfortunately, some doctors say diphtheria is not infectious nor contagious. These persons must be met and if such a one purposely diagnosed wrongly, his is the responsibility. The law must name those diseases to be reported; then the health authorities must be empowered to act, to isolate, either at home or remove to a hospital. Placarding is very necessary. It protects the community and discourages indiscriminate visiting. The public must be informed how to avoid the disease. The law must not permit placards to be removed, and must require in case of death that the body be disinfected, placed in a coffin in as short a time as possible and not again exposed. The funeral must be private, and the burial speedy. Under no circumstances should children be permitted at the funeral. The services, if any, should be brief, and no transfer of the corpse allowed to another house. Heads of families and heads of churches should be held responsible for infraction of this law. The law should also authorize the thorough disinfection of the premises, the clothing, everything, and this must be done by the authorities, not trusted to the family. He had great faith in fire, hence burn up all articles that can be so treated. Vehicles in which such bodies are removed should be prescribed by law, as often disease is spread by the use of a carriage in which others ride with the corpse. Schools are hotbeds for the spread of disease, hence the law should prevent return to school till all danger is past. Certificates of the danger being past should be demanded, and these based on the bacteriologic examination. Next, certificates of vaccination required before entering school should set forth a successful result. Again, those who have suffered with variola should not be allowed to mingle with others till pronounced free from infection whether by their clothing or persons. The law should not permit the transfer, in any way, of furniture so infected, as this is a common mode of carrying disease. No buildings should be rented until fully disinfected satisfactorily to the authorities. Dr. McIntire gives excellent advice but the law must stand by and enforce these provisions.

MAJOR M. VEALE read a paper on "Compulsory Vaccination. Will Vaccination Protect?"

DR. W. M. WELCH, in charge of the Municipal Hospital for Infectious Diseases, Philadelphia, speaks from an experience of twenty-five years, and nearly 6,000 cases. Variola 2,831 cases; deaths 1,534, per cent. 54.18; varioloid 2,169 cases; deaths 28 per cent. He says: "All unvaccinated cases if recovery took place, were disfigured for life; all vaccinated after a few months showed little if any appearance to indicate that they had suffered. Whole families have been brought to the hospital, all the unvaccinated ill with smallpox, the vaccinated children not." He gives the most positive testimony to this end. During all these years he saw no nurse, laundress, cook, etc., when properly vaccinated before going on duty, take smallpox. He believes that if all persons were properly vaccinated in infancy and again at puberty, smallpox would disappear. Dr. Severidge, an eminent Scotch physician, gives similar testimony. The Board of Health of Philadelphia, from its experience demanded the right to enforce vaccination.

DR. A. H. DORR, Health Officer of New York, considers it evident that the people of this country are not protected as they should be. Many children remain unvaccinated as late

as the fifth or sixth year, and revaccination receives practically little consideration. In London, in 1790, in 100,000 persons there were 712 deaths; in 1883 the average was 3.40. Primary vaccination but not re-vaccination is compulsory in England; in Germany both are compulsory, and the deaths in 100,000 were 0.30. This proves the need of vaccination. Neither prejudice, ignorance nor any other personal consideration can intervene to prevent the law-making power which has been lodged by the people with the government of the State, to make all needful regulations touching the security of public health and human life. This power in the State is qualified only by such conditions as to the manner of its exercise as are necessary to secure the individual citizen from unjust and arbitrary interference.

DR. J. T. ROTHROCK, of the State Forestry Commission, was invited to the privileges of the Association, and spoke in reply on the great need for a number of public reservations to preserve the forests, and which he said would equal, if not surpass, the sanitary surroundings for which the Adirondacks were so famed.

A resolution was unanimously adopted urging this upon the attention of the Legislature.

At the afternoon session, it was agreed to petition the Legislature for \$1,000 to publish the proceedings of the Association.

MAJOR VEALE having presented the subject of the "Need of Hospitals for Tuberculosis," a special committee was appointed on that subject.

By request, DR. W. B. ATKINSON detailed the proper methods for prevention of diphtheria by the use of chlorin and sulphur in the infected house. The laws of the Association were amended to admit as Associate Members all who had formerly been members of local health boards, etc.

#### THURSDAY SESSION.

The officers for 1895 were elected, as follows: First Vice-President, Major M. Veale, Philadelphia; second Vice-President, Crosby Gray, Pittsburg; third Vice-President, Dr. W. E. Allen, Scranton; Treasurer, Dr. J. C. Green, West Chester; Secretary, Dr. Wm. B. Atkinson, Philadelphia.

On motion, His Excellency, ex-Governor Robert E. Pattison, was made an Honorary Member. The Legislature was petitioned to pass acts for the creation of township boards of health, as well as a number of other acts tending to aid in the proper sanitation of the State.

DR. HUGH HAMILTON, Harrisburg, exhibited and explained charts showing the relation of topography and sewerage in the town.

M. G. LIPPERT, C. E., read a paper on the "Best Means of Educating the General Public in Matters of Practical Hygiene." Under hygiene we understand that branch of science which treats of the preservation and promotion of health. Sir John Simon says: "Ignorant men may sneer at the pretensions of sanitary science. Weak and timorous men hesitate to commit themselves to its principles, so large is their application. Selfish men may shrink from the labor of change. Wicked men may turn indifferently from considering that which concerns the health and happiness of millions of their fellow creatures, but in the great objects which it proposes to itself it transcends in importance all other sciences, and in its beneficent operation it seems to embody the spirit and fulfill the intentions of practical Christianity. Yet there is less attention paid to its study than any other branch of science. It is uphill work to interest the public; we have to look to the schools to lay the foundation. Physiology and hygiene as taught in the schools is nothing but a series of temperance lectures and an effort should be made to interest our legislators to amend the laws and allow of a more rational instruction in hygiene. Once properly taught, time is only needed to have it exert a beneficial influence on domestic and public life. We must not wait, but educate our cotemporaries by disseminating information through the press, pamphlets, circulars, etc. Our own State Board is doing good work and local boards can aid in epidemics by publishing these matters in their local papers. The people are led to study them and thus we educate them. Unfortunately, epidemics are needed to waken them to this study. Health journals play an important part; monthlies are now publishing articles on the subject in an attractive form; sanitary associations are also aiding, but best of all are local sanitary associations. Voluntary sanitary committees have been formed in a number of localities in the State. These should be instituted everywhere, and the women should be enlisted and then trust to their good sense, tact, influence and enthusiastic coöperation. We find by their Health Protective Associations in Philadelphia, Pitts-

burg, etc., that they are fully alive, and smaller places may pattern after these. Physicians, civil engineers, lawyers, editors, etc., should be called on by the ladies to aid by their intimacy with many points. Let us all make the effort and organize our own communities. It may take time, patience and perseverance, yet it is worth the effort.

After some discussion Dr. Groff offered the following:

WHEREAS, It has been affirmed that the instruction in hygiene and sanitary science in the public schools of the State is from books, unreliable and without scientific standing; and,

WHEREAS, These allegations are denied; therefore be it

Resolved, That the President appoint a committee of three to examine the books in use and the methods employed in teaching hygiene and sanitary science in this State, said committee to report at the next annual meeting of this Association.

The committee was increased to five and the resolution adopted.

Dr. J. S. CARPENTER, of Pottsville, read a paper on "Typhoid Fever," giving details of the epidemic at Mt. Carbon, with charts showing the gradual progress of the disease from the initial case.

Dr. E. G. MATSON, of Pittsburg, read a similar paper, showing how the disease progressed in cities.

Dr. J. C. HUTTON, Health Commissioner of Harrisburg, exhibited and described diagrams of hospitals for contagious diseases in cities and towns of modern size. He showed how readily and cheaply such hospitals could be prepared and fully relieve the locality of the dread pestilence in their midst. This attracted much attention, and regret was expressed that the time did not permit of a visit to such a building some miles out of the city.

Dr. E. LEE spoke on the proper use of disinfectants, detailing the best for each special occasion and the need of their use, with proper intelligence, the frequent waste and improper use giving rise to false security and the continuance of disease.

A special committee was appointed to prepare a code of health laws for the State, that all Boards may work under uniform conditions.

Prof. T. M. DROWN, Chemist of the Massachusetts State Board of Health, addressed the Association and a few members of the Legislature in the evening, showing how the work was being done in his State, and the good flowing from it in the way of water supply examinations, etc.

## SELECTIONS.

**Symptomatology and Diagnosis in Spinal Traumatism which Involve the Osseous Framework.**—Abstract of an essay read before the Section on Surgery at the International Medical Congress at Rome, April 3, 1894, by Dr. T. H. Manley, of New York. Dr. Manley said: "The symptomatology of osseous disorganization in traumatism of the spine is anything but definite; the bony segments of the vertebral column are so deeply lodged, so powerfully braced, and so shaped and heaped on each other by such an imbricated arrangement that nothing less than great and concentrated violence can cause a fracture of them, and when it does occur in the large majority of cases there is no visible or palpable displacement. In the greater number the cord entirely escapes, or only suffers such trivial contusion that nothing more than a temporary numbness at the periphery, supplied by the nerve roots beyond the site of injury, follows. In the greater number of cases the apophyses alone suffer fracture when the transverse spinous process or posterior neck is involved; but it is only when the displacement of the fragments is inward and the cord is crushed through that symptoms of paralysis or paraplegia follow. There is every reason to believe that the spinal cord can bear moderate compression and laceration, combined with considerable longitudinal tension, without sustaining any serious damage. Experimentation has clearly proved that the spine may sustain fracture involving the apophyses and extend completely through the bodies without a single neural symptom following. In several animals on which I have instituted experiments to determine this question, I was able to produce the most extensive description of fracture, in several of which the spinous body was completely fractured horizontally across and through, thereby producing a distinct communication between the posterior mediastinum or pleural cavity and the spinal canal; and yet no paralysis of any kind succeeded the physical violence employed. Spinal

fracture possesses no definite symptomatology; therefore, it may be said, its diagnosis in many cases is quite impossible.

"Fortunately for the patient, the failure to accurately locate and appreciate the precise extent and character of the fracture in no important manner influences treatment. Of late, since the advent of the antiseptic method of wound treatment, some have advocated the making of a free incision over the plane of suspected fracture, when we would be enabled to freely explore the suspected area and, if need be, at the same time deal with the displaced fragments. At first sight this might seem a rational and prudent line of action, though if we investigate but superficially into the anatomic, structural composition of the spine, and consider what occurs in a fracture in this region, we shall the better appreciate its fallacious foundation. The spine is not, as has been alleged, in any manner analogous in structure or arrangement with the head; and therefore, because we may generally, readily, and safely expose the brain the same can not be done with the spinal cord. The spinal cord, being very deeply lodged, is always very difficult of access and requires an extensive sacrifice of bone in order to make an opening of ample size to explore and manipulate through. And now, after our incision, which in this region is always attended with a great loss of blood where the bones are exposed: *a*, there may be no fracture; *b*, one or more fractures may escape detection; and *c*, if the fracture involves one or more of the bodies our posterior incision will avail us nothing, as the cord fixed in position by its nerve roots, obscures our view of their posterior surfaces. If, however, there has been a positive depression of the bony fragments on the cord and it is completely crushed through, of what avail will be an exploratory incision or a laminectomy in the way of repairing or restoring an organ totally destroyed beyond the point of compression? Not only is the diagnosis of spinal fracture often attended with quite insurmountable difficulties on the living, but even on the cadaver it may very often escape detection or be but imperfectly recognized by the *en courant* method of making necropsies on those who are presumed to have succumbed to spinal injuries, or they are associated with other internal complications. A post-mortem examination of the spine for a traumatic lesion of it, in order to be thorough, exact, and of any scientific value, always requires that the entire spinal column should be completely detached from the occiput, ribs and sacrum. Then it should be brought into good light, and segment after segment, when the soft parts have been removed, be carefully manipulated and scrutinized. When the examination has been completed it may be returned and fixed in the breach from which it was removed and be covered in."—From the *London Lancet*.

## NECROLOGY.

R. C. CHENAULT, M.D., February 8, at his home in Glenview, near Louisville, of pneumonia. Dr. Chenault was born near Richmond, Madison County, Ky., and was a brother of Col. Waller Chenault, of Morgan's command, who was killed in the battle of Green River Bridge, and a cousin of Prof. J. W. Chenault, the well known educator of this city. He was graduated from the Jefferson Medical College, Philadelphia, and on his return formed a partnership with Dr. Alexander R. McKee, a noted physician of Central Kentucky. Later, he was appointed by Governor Leslie as Superintendent of the Eastern Insane Asylum at Lexington, Ky., which he managed with ability. After retiring from that place he established the High Oaks Sanitarium at Lexington. Three years ago he removed to Louisville, and retired from active practice. He was 60 years of age and a life-long member of the Baptist Church. His remains will be buried in his old home at Richmond, Ky.

D. H. OLIVER, M.D., of Indianapolis, February 3.—Jessie D. Wood, M.D., of Topeka, Kan., February 2.—Nimrod Thompson, M.D., of Smyrna, Tenn., February 1, aged 83.—F. R. Graham, M.D., of Chester, Pa., January 27, aged 69. Cyrus Falconer, M.D., of Hamilton, Ohio, January 28, aged 85.—John K. Stark, M.D., of St. Louis, January 26, aged 66.—J. O. Whitney, M.D., of Pawtucket, R. I., January 23, aged 72.—C. A. Morse, M.D., of Cambridge, Mass., January 31, aged 83.—G. A. Rex, M.D., of Philadelphia, February 4, aged 50.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

## SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

## MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, FEBRUARY 16, 1895.

## HYPNOTISM AND CRIME.

Our readers will recall that a few years since there was much written on this subject in French journals relative to the celebrated case of GABRIEL BOMPARD, who committed a capital crime while, as she claimed, under hypnotic suggestion. Of late there has been a revival of the discussion in this country, and one man has been acquitted of murder and his alleged hypnotizer convicted. In another place a reign of terror has been established not unlike that which prevailed in Salem during the celebrated witchcraft epidemic.

While the general phenomena of hypnotism have been fairly well understood by the profession, a very exaggerated opinion of the power of this condition has obtained among the laity. Sensational novels of the Trilby order have done much to spread, not a knowledge of hypnotism, but a more or less distorted caricature illuminated by the fervid necessities of the story writer.

Sensational views like the above will be scouted by the scientific, yet there is a sufficient substratum of truth in the phenomena of hypnotism to make its medico-legal relations of great importance. It is a singular fact that even recent works on medical jurisprudence, notably the "System of Legal Medicine" (R. B. TREAT, 1894) practically ignores the forensic aspects of the subject.

One great difficulty in defining the forensic relation of hypnotism was to get some fixed point. It all seemed so vague and intangible that the application of legal rules appeared to be hopeless. This difficulty has been overcome by an article from the pen of THOMPSON JAY HUDSON (*New York Medical Journal*, Jan. 26, 1895). The writer rejects the theo-

ries of CHARCOT and RICHER, that hypnotism is but a phase of hysteria and accepts the definition of BERNHEIM, that it is "the induction of a peculiar psychical condition which increases the susceptibility to suggestion." It is the view that hypnotic influence is an essence or current, that proceeds from the operator, and not a subjective state only in the person hypnotized, is what gives this subject such terror for the ignorant.

MR. HUDSON shows how the prevalent view that a person may be induced to commit a crime while under its influence, is brought about by the fact that a person in such a state usually accepts the will of the operator as his own. If the operator suggests that he is an angel or a demon, he will act the part to the life within the limits of his mental and physical capacities. He points out how these facts with the various laboratory experiments have been made to do duty in formulating a very incorrect idea of the power of suggestion while in the hypnotic state.

The laboratory experiment in which a hypnotized person is given a dagger and informed that it is a real dagger, and told to strike at another person, is supposed to represent what might actually occur in real life were the hypnotizer an evil disposed person who wished a certain crime committed and had the subject well under control. MR. HUDSON points out how very erroneous such a deduction would be, for he says the conditions are very different in real life. In a laboratory experiment, the one who is hypnotized knows he is surrounded by friends, that no possible harm will come to him or to others, and that in yielding to the will of the operator no chances are taken. These unconscious or what HUDSON terms, auto-suggestions are the real ones which influence the hypnotized person, that is, if one suggestion counteracts another, no action will take place. If one is stronger than another, action will take place along the line of least resistance. He therefore divides auto-suggestions into four classes: 1, volitional; 2, moral and educational; 3, instinctive; and 4, environment. Therefore the argument becomes simply this, that in a given case, if a person in a hypnotic state has a criminal act suggested to him, if he yields to that impulse, he is essentially a criminal in his nature. If, on the contrary, instinctive, moral or educational suggestions are encountered, the act will not be done. That this is a fact, and that very little importance can be attached to the laboratory experiment, is well shown by the example cited by DR. JAMES R. COCKE, of Boston. Standing in front of a deeply hypnotized subject, he placed a card in her hands, telling her that it was a dagger, and commanded her to stab him. This command was immediately obeyed with the greatest alacrity. He then handed her an open pocket knife and again commanded her to stab him. She raised her hand as if to execute the command,

but hesitated and immediately had an hysterical attack, which put an end to the experiment.

The explanation of the foregoing is to be found in the instinctive and moral auto-suggestions previously existing in the mind of the patient. If they are of sufficient strength to overcome the oral suggestions of the operator the act is not committed; if, on the contrary, the auto-suggestions are imperfect they will not neutralize the oral promptings and the latter suggestions will prevail.

It will be seen, therefore, that no new psychical elements are introduced into the problem, but the old ones of criminal surroundings and environment which furnish the motive for the commission of all crimes. The logical deduction from these premises is that hypnotism as a defence for crime can have no standing in a court of law; that the commission of crime is as much determined by the moral character of the individual in a hypnotic state as it is in his waking moments.

#### THE PATHOLOGY OF NEURITIS.

The importance of the pathologic condition of neuritis or inflammation of the nerves has been fully recognized only in a comparatively recent period. In the older books it is often only mentioned as a rare or exceptional condition, and as late as twenty years ago text-books on nervous disorders scarcely noticed it, or did so only as a possible complication of other diseases and of traumatisms. Still its importance and prevalence were emphasized by a few leading authorities, notably, REMAK, ERB, WEIR MITCHELL and others, and it can not, therefore be regarded as a new discovery in pathology; it was rather only an overlooked fact by the many, and was acknowledged but by the few. The recognition of the frequency of neuritis in later years may perhaps be said to date from the elaborate discussion of the subject by FRIEDREICH in his monograph on progressive muscular atrophy and by ERB in ZIEMSEN'S "Handbook of Special Pathology and Therapeutics," and the writings of WEIR MITCHELL in this country, who demonstrated its importance at a comparatively early period. At the present time it plays an increasingly important rôle in nervous pathology and is found connected with a very large proportion of all the general systemic infections. It formed the subject of an interesting discussion at the Congress of French Alienists and Neurologists last year, where the prevalent view seemed to be that, except in special traumatic cases and those due to cold, etc., it is largely the result of some morbid agent acting on the nervous system. Whether this acted primarily in the nervous centers as held by ERB and others, or whether the action is peripheral throughout was not unanimously agreed; in a few conditions, such as lepra, it seems probable that we shall have to admit

a purely peripheral infection and the later involvement of the centers as due to an ascending neuritis.

Two forms of neuritis, it was held, should therefore be recognized, the descending and the ascending, the former probably secondary to alterations in the brain or cord, and the latter a peripherally originating affection in which the higher centers are only secondarily affected. It was shown that the apparent intact condition of the central nervous system in many cases of polyneuritis did not necessarily imply that they had no part in the pathology of the affection, but only indicated that the changes recognizable by our methods were located in the peripheral nerves. Inflammation of the nerves is readily transmissible as irritation, only appearing in its fully developed form at points of special weakness, the "neuritis migrans" of KLEHM and others, and the periphery of the nervous system is in many ways one of its most vulnerable parts.

A very important communication on this subject is that of EDINGER, in which he offers what is to a considerable extent, a new explanation of the pathology of neuritis. Basing himself on the facts that active function of an organ involves its structural change, a tissue waste which under normal conditions is restored, but in conditions of weakness or innutrition leads to retrogressive alterations, and that a weakened and ill nourished tissue gives way and is encroached upon by the more active and healthy structures, he accounts for neuritic disorders by supposing a disproportion of function and restitution in the nerve, and proliferation of the interstitial tissue, the neuroglia, at the expense of the nervous elements and hence general nerve degeneration or neuritis. It is this encroaching of healthy upon diseased tissue that according to WEIGERT constitutes interstitial inflammation and sclerosis, and it has the effect of still further mechanically embarrassing and ultimately destroying function.

This theory does not do away with that of the generally infectious or toxic origin of neuritis, but it is perhaps the best that has been offered to explain its mode of operation. It is easy to see how under the influence of some abnormal agency the exhausted nerve elements may fail to undergo proper repair and neuritis ensue, and the theory has also an important and obvious bearing on the therapeutics. It also helps to explain many peculiarities, such as the proclivity of certain nerves to the neuritic process, the mild neuritis of old age studied recently by OPPENHEIM, etc. In many ways it clears up the hitherto somewhat dubious pathology of the disorder.

#### MEDICAL JOURNALS.

An old member of the ASSOCIATION, and one whose business qualifications have commanded scarcely less respect than his known professional skill, has sent

the editor a copy of a letter he addressed to a friend who consulted him about starting a new medical journal.

The reply ran something like this:

*My Dear Doctor:*—Your courteous letter asking my advice about starting a new journal is at hand, and in answer I have to say frankly that in my opinion we have too many medical journals now. Let us do our best to improve those we have, by contributions and pecuniary support and thus advance American medical literature.

Yours very truly,

No one can look over the list of medical journals without realizing that our fellow member told the truth. The essence of success lies in concentration. The scattering of energy and force is sheer waste. There are many medical journals worthy of life and continued existence. They have a field. Let them be supported. But when the day shall come that every two medical men own a medical journal, and every six medical men manage an alleged medical college, it is time to speak frankly on the subject. A half supported medical journal is a half starved one, and a half starved medical journal bears on its face a mute but appealing cry for sympathy and support which is quite as plain, as if the words were distinctly expressed.

Nor is medical science or the profession generally benefited by increase in the number of the journals. On the contrary, many a valuable article is lost or worse than lost by the obscurity in which it slumbers, an obscurity which grows deeper and deeper with the mutations of time.

#### A MATTER OF NOMENCLATURE.

The term, antitoxin, now so extensively employed to designate the sterilized blood serum of an animal rendered immune to a specific disease, is in some respects an unfortunate one. About four years ago it was applied to one of the coal tar derivatives and a company was formed in England for the purpose of exploiting the drug as a proprietary preparation.

It may be doubted whether the term is sufficiently specific to be applied to a single preparation, but is rather to be used in a general sense the same as antipyretic, antacid and antiscorbutic have been so long employed.

The term serum therapy, is an excellent one and ought to be retained, but "*heil serum*," that has been employed to designate the remedy for diphtheria is certainly very unfortunate as applied to a single product.

Why not drop the prefix anti, and simply compound the name of the disease with serum, thus "diphtheria serum, fifteen hundred antitoxin units?" Subsequently we may have varicella serum or scarlatina serum. The method is simple, expressive and avoids some of the confusion into which we have fallen.

## CORRESPONDENCE.

### Corwin's Double Binaural Stethoscope.

CHICAGO, Feb. 12, 1895.

*To the Editor:*—The accompanying cut represents the instrument which I have used in class demonstration of physical diagnosis in Rush Medical College for the past two years, with very great satisfaction both to myself and the students. By it both teacher and taught are enabled to hear sounds under like circumstances of time and place, and the instructor is therefore sure that what he hears and describes is heard by the student. Demonstration of sounds by the use of separate stethoscopes is sometimes tedious and uncertain, owing to the varying manner of applying the instrument, and the variable occurrence of adventitious sounds both in time, place and character, owing to the difference in the depth of respiration, occurrence of cough, and the various changes, functional and pathologic, which take place within the body.

The first instrument made, was a combination of two of Knight's stethoscopes, united by a common chest piece. While this proved the practicability of the idea, I have as regards durability, pliability and compactness, obtained a very serviceable instrument by uniting two of my own stethoscopes as represented. The same scheme has been carried further by a combination of four instruments with a common chest piece. But this has no further advantage other than that of a possible time-saver.

I recommend the double stethoscope to the profession as being of use possibly in some cases of consultation, but especially to those who are engaged in teaching this branch of medicine.

A. M. CORWIN, M.D.

### An Old Instrument for Intestinal Anastomosis.

THE PRECURSOR OF THE BUTTON.

CHICAGO, Feb. 12, 1895.

*To the Editor:*—About seventy years ago a surgeon named Denans, in France, reported to the Royal Medical Society of Marseilles his experiments with an instrument acting on the principle of the intestinal button. The report was published by the Society in 1826. (*Recueil de la Societe Royale de Medicine de Marseille*, 1 an., No. 1, 1826.) Chelius, of Heidel-

berg, quotes it in the sixth edition of his "System of Surgery," translated by South in 1847, (vol. III, p. 509) in the following words:

"In complete division of the intestine, Denans introduces into the upper and lower end of the gut a silver or zinc ring, thrusting it inward about two lines from each end; he then brings the two ends together over a third ring, of which the two springs retain the external rings. The included ends of the intestine mortify, and the rings thereby becoming unfastened are discharged by stool, after they have united the serous surfaces in contact. This experiment in the dog has most successful results."

It is not clear that Denans tried his instrument on human beings.

EDMUND ANDREWS, M.D.

#### American Medical Publishers' Association.

ST. JOSEPH, Mo., Feb. 6, 1895.

To the Editor:—Please be kind enough to announce in your next issue, the meeting of the American Medical Publishers' Association, which will occur on May 6, 1895, at the Eutaw House, Baltimore, Md. A program of interesting papers is being prepared, and a full attendance of the medical publishers of the United States is desired.

Yours very truly,

CHARLES WOOD FASSETT, Secretary.

LONDON B. EDWARDS, M.D., President.

### BOOK NOTICES.

**Relations of Diseases of the Eye to General Diseases.** By MAX KNIES, Professor Extraordinary at the University of Freiburg. Forming a Supplementary Volume to every Manual and Text-book of Practical Medicine and Ophthalmology. Edited by HENRY D. NOYES, A.M., M.D., Professor of Ophthalmology and Otology in Bellevue Hospital Medical College, etc. Octavo, 470 pages, illustrated, extra muslin. Price \$4.25.

The doctrine of mutual interdependence taught by the fable of the belly and the members, was taught by what was apparently thought at the time a self-evident physiologic fact. Yet there is little doubt but the practitioner who palpates the abdomen, and searches the test meal carefully, usually forgets that the patient has any eyes, and the ophthalmologist as blindly ignores the fact that his patient has any stomach or any nervous system beyond the optic nerve. To be the mutual friend and Mentor, and perhaps referee between various specialists and the general physician and general surgeon is the object of this book, and it would seem on examination as if every possible connection between abnormality of the eyes, and injuries and diseases of the remainder of the body, was enumerated in its proper order. The book is not one to sit down and read from "title page to colophon" as one would a novel or a new book on serum-therapy but rather one for reference, in particular cases, as one looks at a dictionary for a particular word. But for all that, few books have been written more philosophically or from a broader physiologic basis. There is no redundancy or padding; the author holds closely to his text and the translator and editor have apparently made little variation from the original. We quote from the opening chapter:

#### THE NERVOUS SYSTEM.

"The relations between the eye and the nervous system are mutual. It is rare to find eye diseases the starting point for diseases of the nervous system. Much more frequently diseases of the nervous system, especially of the central organs, cause disorders of the eye. These may be of a functional character, or may be objectively visible, such as stasis, inflammation of the optic nerve, exophthalmus, spasm and paralysis of the ocular muscles, etc. The functional disturbances of the eye often constitute important local symptoms and are indispensable in the local diagnosis of

brain diseases. On the other hand, the changes visible with the ophthalmoscope in the optic nerve, retina, vitreous body, etc., are of a more general character, and usually enlighten us rather as to the character, than the location of the disease of the brain."

Again, page 265:

#### DISEASES OF THE DIGESTIVE ORGANS.

"While there are manifold relations between diseases of the skin and the eye, this is true only to a slight extent of diseases of the digestive organs apart from a few very general occurrences."

And then follow reports of poisoning from the instillations of various medicaments into the eyelids, and the escape of the same through the nasal duct into the pharynx, ocular affections from diseased teeth, visual weakness from hemorrhages, yellow vision in jaundice and the like.

Taken all in all, this book occupies a unique place in medical literature and will be a valuable addition to any library not already possessing it in the original. The American editor has made some valuable additions, and has done his part well.

### PUBLIC HEALTH.

**Smallpox in Chicago.**—There is a gratifying reduction in the number of new cases of smallpox in Chicago during the present month. Between January 1 and February 12 inclusive there was a total of 240 new cases, but of this number 201 occurred in January—a daily average of 6.5—and only 39 in February—a daily average of less than 3.3. The death rate is correspondingly reduced; for January the mortality was 17.2 per cent.; for the first twelve days of February it is 9.6 per cent. The total number of cases under treatment since January 1, has been 324, including 84 remaining over Dec. 31, 1894; remaining in hospital, midnight of February 12, 91.

**Antitoxin as a Prophylactic.**—During the epidemic of diphtheria last December, noted in the JOURNAL at the time, the Children's Hospital at Boston, Mass., was so seriously overcrowded that applications for admission were refused. It is reported that the disease recently appeared again in the institution and the diphtheria antitoxin was freely used as a prophylactic. All the patients were given an injection of the serum and admissions were allowed only on condition that each child should be so treated on entrance. It is asserted that all cases of diphtheria entered for treatment were cured, and that there was no extension of the disease among the new admissions, the immunization being complete.

**An Absurd "Pure Food" Law.**—The absurdity of the legislation against oleomargarine in the interest of "pure dairy butter" was laughably demonstrated last week at the annual meeting of the Pennsylvania State Dairymen at Meadville, Pa., when prizes were offered for the best butter exhibited. Mr. A. J. Palm, editor of the Meadville Messenger, who has strenuously opposed the present State law against "imitation butter," sent to Chicago for three packages, which he exhibited as butter and gave the names of three of his dairymen friends as exhibitors. The one pound package of imitation received second premium and a third premium was awarded on the five pound package. The five pound package of imitation butter scored one point higher than the best dairy butter in the one pound package.

**Stamping out Tuberculosis.**—It is estimated that it will require \$500,000 to stamp out tuberculosis among the cattle in the State of Massachusetts. The following are the figures submitted at a meeting of the Committee on Public Health and Agriculture of the Massachusetts Legislature recently:

Whole number of cows in the State, 186,806; neat cattle other than cows, 47,528; number under one year old, 15,000; total number, 249,334. Ten per cent. of these being the number estimated to be infected, 24,933. Average value of these at \$20 apiece, \$498,660. Cost of making the test and sundry expenses, \$101,340, making a total of \$600,000, to which should be added \$50,000, for salaries for the commissioners for five years, making a grand total of \$650,000.

A bill before the Michigan Legislature provides that all persons before they can teach public or private schools in Michigan shall be examined and obtain a certificate from a physician that he or she is not afflicted with any communicable form of consumption. In support of the bill it is asserted that teachers having the disease have communicated it to their pupils simply by coughing and expectorating on the floor. Another bill before the same body calls for an appropriation to buy ground in the vicinity of the city of Ann Arbor whereon to build and equip a consumption hospital.

**Hygiene of Paris in 1894.**—The movement of the population of a city of 2,500,000 inhabitants constitutes a source fecund with practical teachings of hygiene, says *L'Union Medicale*. Pathogenic influences are felt there so keenly and translated in such exact proportions that they are amplified, so to speak, as by a projecting instrument. When the temperature is lowered suddenly the number of pneumonias is correspondingly elevated; when from any cause it is necessary to turn the Seine water into the city pipes, the typhoid curve is elevated and remains so during the time of this exceptional distribution; when a small epidemic of variola develops, the number of vaccinations is multiplied, and soon the disease falls below the normal. Differences of detail, errors in diagnosis,—all causes of error fade away before the authoritative evidence of large numbers. The year just ended is particularly interesting and the weekly bulletins of the municipality furnish the necessary figures. The first thing that strikes one is the notable diminution in the general mortality. It is more than a tenth lower than the mean of the three preceding years. And what is still more remarkable this diminution is not found in the communicable diseases. Typhoid fever, variola and phthisis, on the contrary, present a rather marked elevation. The first two, in fact, assumed somewhat the nature of an epidemic at the beginning of the year. Diphtheria alone fell below the mean. The following table shows these differences more clearly:

Year.	Typhoid Fever.	Variola.	Diphtheria.	Tuberculosis.	Total Mortality.
1891 . .	476	39	1,361	11,895	52,558
1892 . .	799	42	1,557	12,153	57,137
1893 . .	649	302	1,465	12,267	52,955
1894 . .	758	183	1,149	12,288	49,079

The constant augmentation of the number of deaths due to disease is also worthy of note. It is in accord with the progressive increase of the population. The Minotaur exacts each year its proportional tribute of young lives without being influenced by anything.

**Etiology of Cholera in Buda-Pesth in 1892-93.**—Detvös, in a communication to the Royal Medical Society of Buda-Pesth, seeks to determine the hygiene of habitations and industrial occupations in the epidemic of cholera in 1892-93, (*Le Bulletin Medical*). He has been able to gather 19,000 observations. It is shown that cholera raged most fiercely in the quarters of the city where non-filtered water was drunk. The new Francis Josef barracks, on the contrary, escaped the epidemic entirely. In a tile factory, where a large number of workmen were attacked it was found that they drank from a clay hole in which fecal discharges had been thrown. In another tile factory, where the disease was also prevalent, choleraic vibrios were found in the drinking water. The disease

disappeared quickly when the use of canal water, artificially filtered, was prevented. Ten and six-tenths per cent. of the patients lived in unhygienic and over-crowded dwellings; 41.5 per cent. were day laborers; most of the others being coachmen or domestics out of employment; 8 per cent. belonged to the upper classes; 22.4 per cent. were alcoholics; 19.6 per cent. had been sick previously and 49.7 per cent. habitually used cold and dry food. M. Detvös was not able to trace any relation between the epidemic and the ground water, the temperature or the humidity of the soil, but abundant rains increased the morbidity. The water from canals artificially filtered was shown to be more infectious and richer in microbes than non-filtered water which was simply left to settle. Persons who drank directly from the Danube furnished a large number of cases.

## MISCELLANY.

**The College of Physicians and Surgeons of New York** was damaged by fire January 27. Estimated loss is \$10,000.

**STUDENT.**—Why does the Belladonna mean "beautiful lady?"

**PROFESSOR.**—Because it is paralyzant to the heart and a sympathetic stimulant, two characteristics of the "beautiful lady."—*The Corpuscule*.

**Giantism a Disease.**—Dr. Charles A. Dana, in the current number of *Scribner's*, discusses the function of the pituitary gland, and—following Marié's discovery, that hypertrophy of this body is frequently followed by abnormal growths—surmises that giantism is simply the result of such hypertrophy, is, in fact, a form of acromegaly. It is thence suggested that it would be interesting to learn the condition of this gland in the pygmies.

**May Testify as to Neuritis Following an Injury.**—In an action for personal injuries where it was alleged that the plaintiff's body was injured by dislocation, straining and laceration, and injuries of muscles, nerves and otherwise, and there was evidence which tended to show that the knee and hip were injured, and that the sciatic nerve became inflamed in consequence, the Supreme Court of Michigan held (*Williams v. Cleveland, C., C. & St. L. Ry. Co.*, decided Dec. 7, 1894) that a physician might give evidence tending to show that, as a result of the injury, neuritis followed.

**Should Go to the Jury.**—When a competent physician acquainted with the facts, and judging from objective symptoms which are consistent with the opinion expressed, expresses an opinion that in his judgment an injury will be permanent, Judge Rumsey, of the Supreme Court of New York, holds, in the case of *Brooks v. Rochester Ry. Co.*, decided October, 1894, the jury may, upon such testimony, find that the opinion is well founded. Certainly, he says, when such an opinion is expressed in that way, the question is for the jury, and not for the court.

**Dangers of Chloroform Narcosis in Diabetic Patients.**—Baixer calls attention (*Centralb. f. Chirurg.*) to the dangers of chloroform in diabetic patients, basing his remarks on three cases of his own and other cases in the literature. On recovering from the narcosis the patients may feel all right but in twenty-four to forty-eight hours they experience a sense of inquietude, then of hebetude, which passes into coma, in which state they very often succumb. Nothing characteristic is discovered at the necropsy. The author has been able to find acetone and acetic acid in the intestines, even in non-diabetic patients. As chloroform in diabetic patients—perhaps by some yet unknown change in metabolism—may give rise to dangerous secondary symptoms ending in coma and death, the author thinks the existence of diabetes is an absolute contra-indication to chloroform narcosis.

**Salicylic Acid Externally in Articular Rheumatism.**—Suspecting that the therapeutic action of salicylic acid in acute articular rheumatism was due to the anti-neuralgic action of the medicament on the rheumatic arthritis, and not to any specific action of its own, M. Maragliano requested MM. Jemma and Marengo to institute experiments on the curative influence of the drug applied locally in the form of an ointment. This mode of administering the acid was found to be preferable to giving it by the mouth; the derangements of digestion—even gastritis sometimes—so frequently observed when used internally do not follow its external application. From the author's researches (*Gaz. d. Osp.*) it is seen that salicylic acid has a decided and constant analgesic property; it acts on the diseased joints like a mild revulsant, not giving rise to any subjective symptoms. Its antipyretic action is very slight, but this is also true of it when given by the mouth.

**Amputation of the Penis.**—Pousson describes (*Ann. de Mal. Org. Gen. Ur.*), a method of amputating the penis which he asserts assures hemostasis during the operation, closes the corpora cavernosa hermetically and produces a sort of artificial hypospadias with a meatus of maximum size and constant permeability. It is a development of the methods of Esmarch, Phelip, Assaky and Guyon. Antiseptic methods having been employed a rubber bougie (No. 18 or 20) is introduced into the urethra which, serving as a support for the penis, facilitates the operation. This consists of three stages: 1, incision of the skin and ligation of the dorsal arteries—the skin is incised at the point where the corpora cavernosa are to be divided; the incision is raquette shaped, with the tail below; the dorsal arteries are then ligated; 2, the division of the corpora and of the corpus spongiosum and suture of the fibrous envelope—the corpora cavernosa are divided a little obliquely, following the skin incision; the corpus spongiosum is dissected up for a centimeter and a half above this and then cut; the fibrous envelope of the corpora is then closed with catgut; 3, establishment of hypospadias and suture of the urethral mucous membrane to the skin—a No. 18 or 20 sound is placed in the urethra and allowed to remain until about the fifth day when it is taken out and by about the tenth day reunion is complete. The author reports three cases, in all of which this method was successful.

**Municipal Power where Smallpox is Epidemic.**—To prevent injury to the health of the public generally, and to its individual inhabitants is, the Supreme Court of Appeals of West Virginia holds, in the case of *Thomas v. Town of Mason*, decided Nov. 24, 1894, one of the most important functions of a municipal corporation, and, when not expressly given, is conferred by implication upon all governing municipal boards, as a part of the police power of the State, delegated to them by the Legislature, so that reasonable by-laws in relation thereto have always been sustained as within the individual authority of such corporations to ordain. And the establishment of a State and local boards of health is not to be regarded as detracting from the general powers of municipal government unless such legislative intent clearly appears. The power to relieve the indigent sick in times of epidemic disease is inherent in every municipal corporation, upon the ground of self-protection; if upon no higher ground. Consequently when there is an epidemic of smallpox or other dangerous contagious disease within the corporate limits, the council of such city, town or village has power to provide for the medical treatment and care of poor persons residing therein. Moreover, this power, it is held, is expressly conferred in West Virginia by a statute which confers upon the town council, and imposes on it, the duty to take care to prevent injury or annoyance to the public or individuals from anything dangerous, offensive, or unwhole-

some, and stating that it shall have power to make and pass all needful orders, by-laws, ordinances, resolutions, rules, and regulations not contrary to the constitution and laws of the State. (Sections 28 and 43 of Chapter 47 of the Code.) It may, therefore, for example, employ a practicing physician of skill and experience to treat certain poor persons for smallpox, who are proper residents of the town. And having power to create a debt, it can, in a proper case, be compelled by mandamus to provide funds for its payment.

**Discovery of the "Missing Link."**—Dr. Eugene Dubois, Dutch army surgeon at Batavia, announces the discovery of what he calls the *Pithecanthropus Erectus*—a supposed intermediate type between the apes and man. This discovery, according to *Le Progres Medical*, has aroused intense enthusiasm in the scientific circles of Europe and, if confirmed, will demolish the anti-Darwinists. M. Dubois found the remains in the lower quaternary of Sumatra. They consist of a well-preserved skull, a femur and a tooth; the two latter were found a few feet away from the skull. The cranium is intermediate between those of the anthropoid apes and of the native Australians. It has the characteristics of the celebrated Neanderthal skull exaggerated, with its enormous supra-orbital ridges. The cranium is 185 ctm. long, 130 broad, and has a capacity of about 900 to 1000 cubic centimeters—a capacity much larger than that of the gorilla, but inferior to that of primitive man. This capacity is found only among imbeciles in man. The tooth, which was the third upper molar on the right, was enormous and resembled one from an ape more than a human tooth. The position of the foramen magnum and the posterior aspect of the skull show it was more nearly perpendicular than in any anthropoid. The gibbon, of all the apes, walks the most easily, yet it is much more differentiated from man than is this skull. We may conclude then that this man-monkey was adapted for walking and a study of the femur confirms this. Dr. D. G. Brinton, in a letter to *Science* says: "One of the bearings of this discovery is upon the original birthplace of the human race. The author believes that the steps in the immediate genealogy of our species were these: *Prothyllobates*, *Anthropopithecus Sivalensis*, *Pithecanthropus erectus* and *homo sapiens*. This series takes us to the Indian faunal province and to the other aspects of the great Himalayan chain, as the region somewhere in which our specific division of the great organic chain first came into being."

**Advance in Medical Education.**—Certificates of having worthily completed the preparatory medical course of the Nebraska State University will hereafter admit students—without entrance examination—to the first year classes in the Department of Medicine and Surgery of the Michigan State University and to the St. Louis Medical College; to the second year in the Northwestern University Medical School, to the University of Pennsylvania Medical Department, to the Omaha Medical College and to the John A. Creighton Medical College; and to the third year of the Cincinnati College of Medicine and Surgery. The preparatory medical course of the University covers a term of three years and is open to students of either sex who have a fair mastery of English grammar, arithmetic, descriptive and physical geography and elementary history of the United States; students possessing higher qualifications are given credit therefore on entering and can thus shorten their term. The first year's work includes a thorough course in English, a course in Latin, algebra to quadratics, the first two books of geometry, logic and elementary courses in botany, chemistry and physics; in the second year structural and physiologic botany, the chemistry of the metallic elements and their compounds with five hours' laboratory work each week, rhetoric and theme-writing, lectures and laboratory work in physics, sound and heat, general osteology, hygiene and sanitation and physical training in the gymnasium; the third year covers pharmaceutical botany, a con-

## ORIGINAL ARTICLES.

### A COMMON INJURY OF THE NERVOUS SYSTEM OF THE MODERN CHILD.

Read before the Southern California Medical Society, Dec. 5, 1894.

BY NORMAN BRIDGE, A.M., M.D.

PROFESSOR OF CLINICAL MEDICINE, ETC., RUSH MEDICAL COLLEGE  
CHICAGO.

Man's place in the universe is determined by the character and development of his nervous system. His brain and spinal cord preëminently determine his character and force. Defects of other organs, as heart, lungs, kidneys and spleen may destroy his life. But defect or weakness of brain and cord, while perhaps permitting him to live long, will handicap him perpetually.

The conservation of the nervous system must be, from birth to death, of paramount importance. Next to the forces that make the general bodily strength and vigor, those that influence the development and automatism of the nervous system are most of all potent in determining the career of the individual; it is true of no other set of organs, as of the nervous system, that impressions and influences of very early life determine the final result.

A child has the natural right to the most successful and complete career of adult life that is possible to it. Any rational sacrifice or discipline in early years is both justifiable and desirable, if it will perfect and round out the life and character as a whole, and give the individual the best chance in the race for success and the greatest aggregate of happiness. Parents have always tried to train their children by their best light, and so as to make the probability of this success the greatest. There can be no discounting the good intentions for their children of the great world of parents. But they have to-day numerous standards and systems of bringing up and educating children for their best good, and many of the systems are in their tendency and results diametrically opposed to others, and the history of the race has witnessed numerous successive changes among the same people. Old systems and ways have been discarded for new ones, always on the theory that the new are better. Changes have sometimes been made in accordance with changed notions of what the highest purpose of a child's life is, but probably not generally nor often.

Nearly all seem to agree that most children may have to earn their bread directly or indirectly, to live in civilized if not enlightened society, and that they ought to have comfortable if not happy lives of peace and amity. The inexorable struggle for existence is never lost sight of by any one undertaking in a large way and seriously the development and care of children. A conspicuous few, however, and those most able to do the very best for their children, do seem to

think a child should become solely an ornamental part of society. The multifarious and manifold changes in methods of education and care of the young in the past, show the difficulties of the subject, and suggest that the last word has by no means yet been said.

Insanity and various nervous disorders that more or less disable their victims are alarmingly prevalent, and probably on the increase among our people. Why this tendency? That the cause spends its force on the nervous system can not be doubted. If a nervous degeneracy of the race is threatened or imminent, the basis of it must be found in some habit of life or development of the individual, and carried on probably through successive generations of individuals.

Nature is a good bookkeeper. It is true of nerve cells, as it is in the philosophy of life, that you can not both have your cake and eat it. Brain cells and all cells are in their capacity for function limited by their inherent and congenital potentiality, differing in different individuals, and always dependent for their best on good pabulum, freedom from effete matter, and time for recuperation after function. Long periods of nervous and mental strain can be compensated for only by longer rest; this is unavoidable if a genuine restoration of power is to be accomplished. Excessive strain of nervous system as a result of passion or indulgence of any sort ends in reduced power that can only be partially restored by prolonged abstinence and rest. Infantile insomnia for a year or two is sometimes followed by some years of excessive sleeping, after which the normal conditions and habits are restored. Look at the army of broken-down men of business and women of society who must absent themselves from friends and business for months together for rest and recuperation by changed conditions!

It is doubtful whether excessive strain of any organ of the body, any set or system of cells, is ever entirely recovered from; for cells produce their successors, and the progeny of severely debilitated cells—potentially debilitated—can hardly be expected to be of the highest or the original standard. Manifestly, sections of the human race are becoming congenitally weaker in integrity of nerve cells, or the tension of modern life is becoming more severe—the power is lessening or the load is becoming heavier.

Among the prevailing nervous affections, short of insanity are: 1, nervous and mental weakness shown on slight exertion, so-called nervous prostration; great nervousness on exertion, and easy demoralization; 2, a tendency to pain, especially in the head, pain on the slightest overwork or severe mental or ocular attention, pain especially in the back (so-called spinal irritation); and 3, hysteria in some of its forms; spasms, hysterical neuralgias, amyosthenia and aberrations of sight. These forms are often in-

terdependent, frequently co-exist, and are interchangeable. Is there any nexus between this class of symptoms and any of the prevalent habits of the people? I think there is.

First of all, the nervous strain involved in life in society in America is greater than formerly, and so brain cells and their power are worn out faster; the load is heavier. Then the unwholesomeness of the lives of many infants and children, on their nervous side, reduces the capacity of their brains to bear worry in their maturity, and so the power is reduced. Nothing illustrates this better than the growth of the hysterical habit, as nothing shows better than that how easy it is for injury to be done to the mental and emotional nature. The hysterical tendency grows by what it feeds upon. Emotional excitement, the shortest step beyond the wholesome limit, is always liable if not certain, to beget emotional lack of stability; then excessive mobility of nervous force in the emotional direction may occur, and frequent and ready explosions. Personal attention received, compliments, praise, produce it to a moderate degree; but personal attention expected, looked for or demanded, cause it to a much greater degree and more than anything else in the world. Indeed, expectation of the attentions of others, their consideration, compliments and applause, the fear these may not be received; grief, chagrin and jealousy at their not coming, or because they are not of the right kind or degree, or just to the liking of the recipient, more than anything else tend to develop the hysterical constitution, and to worry and wear out the nervous and mental resources. That mental worry and not work wears us out is an old true doctrine. But worry is an emotion entirely, and certainly for many people the secret of happiness is to minify or destroy this emotion.

The history of medicine is full of examples of disease produced by the carking emotions of an over-desire for attention, and of jealousy. Wier Mitchell has described them and their treatment. With these people, to a singularly morbid condition of mind is added the most amazing system of tricks and deceptions to induce sympathy. A patient refuses to eat, and is the wonder of the neighborhood—she eats surreptitiously. One is completely bed-ridden and can not eat without vomiting—she does sometimes actually vomit—but her nurse is pledged to keep as a secret the fact that she walks about at night and eats freely and retains her food. One woman, a supposed wreck of nerves, keeps up her high fever for weeks by sending the nurse out of the room for some trifle whenever her temperature is being taken, and then shaking the mercury upward in the thermometer. There is no manner of deception short of crime, if crime even has been the limit, that such patients have not perpetrated at the behest of their insatiable craving.

These morbid states grow out of perfectly normal love of the companionship and fellowship of mankind; it is only normal emotion run mad. Imagination, love of companionship belong to every child; we can not stop nor curb them much, nor should we care to; it is the morbidity that kills, and the habit of exaggeration and emotional, even hysterical, exaltation is a thing that comes to children, in a smaller way, as truly as to men. No observing physician who has treated many nervous children has failed to note how quickly some of these develop symptoms that are inquired about in their hearing; how they often

complain of pains and other morbid phenomena, wholly as a result of suggestion or mimetism.

The treatment is to take away all the incentives to the deception by stopping absolutely all gratification of the morbid emotions. Nobody is allowed to speak to the patient for days who could possibly express sympathy, or pity, or wonder, and the treatment is usually successful. The fuel is cut off, and the flame dies.

For the neuralgias, nervous prostration and the inability for connected thought, no treatment is so successful as perfect rest, and freedom from care and worry. It consists, in other words, in freeing the mind from every influence that has caused the trouble, and putting it and the body in a wholesome state of good hygiene. If the recuperation can be complete, and the causative influences can be avoided, the brain does not fall again into the same condition. The remedy for the trouble is to avoid the cause.

One of the first experiences in the life of a child after birth is of caressings and other proofs of affection. These are precious to the groping susceptibilities of the new being, as they are precious through life. But perhaps before the end of the first week the child has, if it be born to parents of nervous temperament, learned to demand these attentions. It must be walked with, trotted or sung to, to court sleep, and soon will not fall asleep otherwise. It could not go to sleep disappointed, and till it gets the sweet pabulum of lulling affection it is disappointed. It finds in its mother's heart the same desire to give as it has to have, and so the habit grows and the child is carried on into years, led, followed, obeyed, played with, entertained, and not a minute to *itself* for its poor brain cells to run in spontaneous action. So he becomes an autocrat in the home; he demands everything, and if he does not get everything he wants, he gets some supposedly good thing in its place, and he certainly receives constant attention and makes incalculable work for every one about him. He must be perpetually amused; if he cries he must be fed, often not good food but goodies; he must be talked to, carried about, drums and music are invoked—anything to satisfy him or stop his crying. He can not sleep unless he is carried in the arms, perhaps for hours, or rocked or sung to; then if the lulling stops he is awake again to demand the same process repeated. And he is withal a very poor sleeper.

We have changed in recent years our methods of dealing with children. Formerly they were taught not only obedience but to be seen and not heard, and seen without ostentation; now we rush the most promising of them forward, and lead them to feel, what is largely true, that the world is theirs, and it is a question whether we have gained by the change.

Many men and women look back with regret on the severe lines of their own childhood, and thank Heaven that *their* children's lot is cast in gentler ones—but the children are less vigorous than their parents, have more pain and discomfort, hysteria and neurasthenia, and can accomplish less in the arithmetic of the world; moreover, they have proportionately fewer children than their parents had, and the latter had fewer than the grandparents. Thus the so-called higher civilization and development, and more indulgence of children in what on the moment they wish for, is constantly deteriorating the race, or a distinct and supposedly favored part of it, while they accentuate its refinements of taste

and increase its avidity for pleasure. They cause such effect of exhaustion of the nervous system of the individual, whether man or child, that a single generation is sufficient to show the reduced resistance to the effects of the environment on brain and nerves.

A great lesson that philosophers of all times have taught is the folly of mortgaging the future for the present, of yielding to the desire for a momentary, intense, present pleasure at the expense of the comfort of the long future. It has been through the ages notorious that adults are in danger of doing this, and Goethe told only the story that was as old as the thought of the race; Faust was merely the example of a class of intense men and women of all times, ready to promise their future to the devil, or anybody or anything, if their present pleasures can be secured. The nineteenth century has witnessed the extension to a large number of children of this sort of sin against mankind, and with both the connivance and assistance of their parents.

Instead of allowing the child what it desires, if it is good and not bad for its development, it is often allowed everything it likes unless it can be seen to be harmful for the moment. With greater companionship and comradeship with their children, parents easily conclude that they should have the same indulgence of pleasures as the grown people. Is it any wonder the children should, many of them, with such latitude, increase their intellectual and nervous speed, and wear out their cerebral dynamos? The wonder is, rather, that we who pretend to think should wonder at it.

What is the remedy?

1. Give the child, if possible, good general physical health. To this end he must have much outdoor life, good ventilation of his rooms, wholesome food in abundance, which he must eat as deliberately as possible. Relieve him of every local irritation or chronic inflammation of any part of his body; for such, especially if of the genito-urinary organs, are sure, in a reflex way, to harm the nervous system, to his life-long and unspeakable injury.

2. This good bodily and brain health can be attained only by long hours of sleep. A child should always go to bed early, *volens volens*, and it should then have its sound sleep out without being awakened. Other things equal, probably not another rule of childhood is so useful as to insist on the largest measure of sleep possible.

3. For his brain's future, be absolutely honest with him. Give him every good and pleasure that will aid his development and strength for the race of life; these will give him a childhood happy enough, and always blessed to look back upon. Withhold the bad things. Be as candid and honest with a child as you are with your insane patients. From such you often withhold what they ask, and insist on what they dislike, and candidly tell them it is all for their good. Why can we not be as fair with the young?

4. If this basis is to be followed, certain definite things in the lives of many children must be omitted. We must, as far as possible, compel a tranquil nervous and intellectual life. Every indulgence that will minister solely or greatly to nervous excitement and emotional exaltation must be refused. Stop walking with the baby and rocking him to sleep. Attend to his normal wants, especially as to food and temperature, then put him in his bed and

let him alone. The instant he finds this rule inexorable he will acquiesce, to his benefit and delight; will have more and better sleep, and gain in nervous strength.

Never "show off" a child. The trotting of him out in public to speak or play or do "smart things" usually panders to his vanity, if not that of his parents, and develops the hysterical disposition. There is no good in it for any child.

Never boast of the exploits of a child in his presence, for it encourages his pride, and pride is a vicious emotion in children as it is in adults—and it is not the quality of self-respect, which is always good.

Avoid any influence that exaggerates or accentuates the sense of personal embarrassment of a child and teach him, if possible, that bashfulness is not a sin, nor a thing to be made fun of.

Don't repeatedly nag the child to preserve the clothes he wears, or about his general neatness or even as to many good manners that he will take on instinctively at his adolescence. We don't try to make infants behave like ladies and gentlemen; then why should we little children, or even big children, at the expense of their regard for us, and the good influence we have over them? Above all things, don't humiliate a sensitive child in public.

For a nervous child, reduce the emotional excitement to a minimum; and for the excitement of play and bustle with other children, which prevents eating or sleeping well, *compel* certain hours each day to be spent alone or with an unemotional person who will refrain from entertaining him. He must amuse himself and rest. A child reduced in weight by lack of food, with poor digestion from bolting the little he does eat, but who plays furiously and to exhaustion throughout his school noontime, and who sleeps poorly and with dreams and nightmare, may often be brought to himself and made a new person by being compelled to stay in the house at least one hour in the middle of the day, and to go to bed early. Left to the resources of his own ingenuity for a time each day, he finds he has an appetite, and he soon has better digestion and sleeps sweetly, and grows in weight and strength. Probably there is no method of correction of a disobedient child so useful in all ways as to make him stop and go to bed in a room alone. He dislikes it, but the punishment is devoid of brutality, and the child rests and thinks by himself.

Stop the course of things in which the child is constantly pandered to, amused and kept occupied. Let him learn to be something of and to himself, work out to some slight extent his own mental salvation, and learn that it is possible for him to stop and think and do nothing for a perceptible time. He may envy other children whom he sees having more done for them, but he will some day look back on the time of youth with a stronger brain than the favored children whom he envied can, and his totality of enjoyment throughout his existence will be greater than theirs.

The brain of every child that is worth much is active in its own way, and quite sufficiently imaginative. We may well direct its activity into wholesome channels of education and equipment for its future, but we are not called upon to increase the normal activity of its brain cells and wear out the powers it ought to have for the more useful years of adult life, or to make for it a new world of fancy and imagination.

tion. All the joys and sweet memories of fairy tales are but a beggarly compensation to a large class of sensitive children who, with the fairy tales unavoidably acquire a belief in the reality of ghosts and hobgoblins, and are for years nightly terrified by thoughts of them. It is no reply to this contention that it is unfair to deprive the child of imagination; nobody ever succeeded in doing this and probably nobody ever will, nor is it desirable to. But let him build up his own imaginative world out of the actualities of his environment and of himself, and he will come to mature years with a maturer and more wholesome and promising mind. Many a boy left to himself in these matters has evolved so much of the philosophy of life that, when, later, he reads Plato and Socrates and Emerson, he seems to be repeatedly confronting the children of his own brain.

Nor does this plea deserve the censure that it would deprive child life of its pleasures. It looks far away from such a calamity. But there are pleasures and pleasures, and the circus and spectacular performance do not furnish the kind of enjoyment that is most lasting or permanently satisfying to a normal child. They wear him out and give him troubled dreams and make him sick. No parent would think of daily sending a child into such excitement. The fatuous sin of modern, evolved and cultivated society is that it is doing its utmost to give its children the same character of excitement, only under different color and in a lesser degree, and not far from six days every week, and then wondering that we have among us a growing army of worn-out children, neurasthenics and emotional invalids.

Los Angeles.

### INEBRIETY AND IMBECILITY—A MEDICO-LEGAL STUDY.

Read before the Association for the Study and Cure of Inebriety, at the Annual Meeting in New York City, Jan. 4, 1895.

BY T. D. CROTHERS, M.D.

SUPERINTENDENT WALNUT LODGE HOSPITAL, ETC., ETC., HARTFORD, CONN.

The following records of two cases bring into prominence again the old conception of inebriety, and the recent modern view accepted by the more intelligent courts and jurors.

In March, 1894, John Cronin was tried and convicted for the murder of Albert Skinner.

"The facts relating to his crime are these: He was a farm laborer 37 years old, living about Hartford. He has been a periodic drinker since early life, and when sober is a quiet peaceable man; when drinking is excitable, irritable, abusive and often quarrelsome. He has been arrested and confined in jail twice for intoxication. His drink periods have been growing longer and the sober intervals shorter for the past few years. He has been growing more irritable and stupid when drunk lately.

"For at least two weeks before the murder he was idle and drank continuously. He was intoxicated on the night before the murder. A few weeks before this time he had a drunken altercation with the man he shot and at that time made a threat to shoot him. Amicable relations were re-established and he seemed to be on good terms with the man, with whom he had formerly boarded and been very intimate.

"On the morning of Oct. 6, 1893, he went to the house of this man, Albert Skinner, and without a word of provocation shot him at the breakfast table. He was pushed and thrown out of the house twice in

a few minutes and stood round on the street near the house with a revolver in his pocket, making no attempt to shoot again and coolly boasting of what he had done. He submitted to restraint and expressed a wish to shoot others also, justifying himself and affirming that he was ready to accept the consequences, and be hung, and if he was permitted would kill others. These expressions of regret that he had not shot more persons were repeated several times.

"He was recognized as having been drinking by his breath and strange actions, but several witnesses thought he was fully conscious of his acts and their consequences.

"For the next two days all the witnesses seem to agree that he was in a semi-dazed condition of mind, indifferent to all surroundings and would not talk. After this his manner changed and he responded to inquiries and conversed, claiming not to recollect any of the past occurrences, and the crime. He said that Skinner, the murdered man, was the best friend he ever had."

This crime was characterized by two very unusual lines of conduct:

1. Shooting the man in open day in his own home, without a word of provocation, boldly and under the possible observation of many persons. Firing only one shot and standing round to see the result, being pushed out of the door by the wife of the murdered man, and going back into the house again, was thrown out by the son; also making no attempt to shoot other persons or run away.

2. Offering no resistance when the pistol was taken from him, submitting to arrest, acknowledging the crime and in violent language expressing a desire to repeat the act on the murdered man and others, and take the consequences. His cool indifference, and violent expressions unaccompanied by acts, or delirious excitement seemed to those about him not to indicate drunkenness, although his breath was strong with the odor of spirits and his manner was strange and unusual.

Thirteen months after the commission of the crime I examined him in the State Prison. During all these months he has been free from spirits, and it would be natural to expect that his condition of body and mind would be very near normal.

His appearance was that of a short, stout-built man, with a small irregular shaped head, retreating forehead, sunken tremulous eyes, large stigmatic ears and high palate arch. He walked with a shuffling unsteady gait, and when seated, supported his head on his hands, and seldom looked up. He answered questions slowly and with hesitation and seemed in doubt unless the questions were direct and repeated. The answers began in a natural tone of voice and dropped down to a whisper at the close of the sentence. This hesitation and doubt differed widely from the cunning reserve of one who would conceal his mental operations, in the apparent feebleness and effort to give some answer and overcome an aversion and incapacity for sustained reason or explanation of any event. The impression given was that of a naturally defective brain, already approaching and evidently in the penumbra region of imbecility.

He appeared in fair health and without delusions, and profoundly indifferent to any past, present or future conditions. As a result of persistent questioning the following facts were brought out, most of which have been confirmed from other sources, hence they are

generally correct: He was intoxicated at about 15 years of age, and has used spirits continuously and at times to great excess up to the present. He both drinks alone and in company, and when intoxicated has little or no recollection of what he does or says. His memory has never been good. At times he can recall events when drinking, at others they are a blank. Concerning the homicide he has no recollection of it; the blank of memory extends from the night before the crime, to some time after being placed in jail.

He can not understand why he should have shot Skinner as he was his best friend. He gave the history of a fall on his head with a period of unconsciousness and a scar showing a scalp wound was exhibited as evidence of it.

Three years ago he was made unconscious by a fall from a railroad train and laid up with injuries of the back and knee for two months. He has been struck on the head several times when drinking and made unconscious. For the past few years when drinking he has been more irritable and quarrelsome and been told that he was crazy at those times. He makes no complaint against any one, and expresses no sorrow or indignation at anything concerning the crime or trial. He is strangely indifferent concerning his life, and would not escape if he could but is ready to die at any time. It makes no difference to him what the result may be.

Concerning the future he has been told that by repentance one can go to heaven; if this is a mistake he will accept the situation. His wishes are of no account as 'the Lord and the law will have their own way.' No questions of his moral responsibility and guilt in this crime, excite any emotion or nervousness, or apparent realization of his condition. He expresses himself coolly and with utter unconcern. At times a half imbecile smile would appear, when he could not answer the question, and did not know what to say. There was no irritation or excitement or depression or annoyance from questions which were pressed, and if different answers were suggested he would select the briefest one.

When the same question was put in a different form, he seemed not to realize it but answered in monosyllables, irrespective of any previous answer. In all this there was no criminal cunning or attempt to conceal or to appear crazy, but clearly the natural working of a feeble and imbecile mind. He seemed to have a remarkably abnormal brain, in which all the higher functions were paralyzed, and the normal consciousness of duty and responsibility were absent.

A study of the heredity of this case was startling.

The near relatives on both his father's and mother's side were hard drinkers, and on his mother's side insanity and epilepsy appear frequently. None of his relatives exhibited anything more than a very low order of intelligence.

His maternal grandparents were William and Mary Callahan, of Country Antrim, Ireland. William died in middle life and Mary lived to be 60 years old, and was insane for some years before her death. Catherine, the eldest daughter, the aunt of John Cronin, became insane from the death of her child and the desertion of her husband, recovering in part and coming to this country, where she died in middle life. Michael, the second child, was early addicted to drinking intoxicants, and his mother tried to kill the appetite by mixing snuff with his drinks. He en-

listed in the English army, was discharged insane and wandered about in the woods and finally died of exposure. Thomas Callahan, the second son, lives in Hartford and is a respectable man. He drank until he was 50 years of age, since which time he abandoned the habit. He testified as to the facts of his nephew's ancestry before the Board of Pardons, and appeared to be a quiet man, "thick" in his memory, and in the appreciation of what the counsel was trying to bring out.

Margaret Callahan, the youngest child of William and Mary, and the mother of John Cronin, was a nervous excitable girl, who went to Wales with her older sister, Catherine. There she married Peter Cronin, a Welsh miner, of a boisterous nature and a man who drank to excess. His wife drank with him daily and they lived in a state of perpetual trouble. At last Peter was murdered in a drunken row and Margaret became insane for a time. Her sister Catherine took her home and adopted John Cronin, who was 1 year old at the time. He lived with his aunt until he was 8 years old, when he was put out to work.

His mother, Margaret, came to this country and married a man named Moran, who is now dead. There were three children by this marriage, one dying in early life and two daughters surviving. One of these, Mrs. George Somers, is subject to epileptic fits, is a hard drinker, and has attempted suicide. She has been in the county jail in this city for drunkenness.

Margaret Moran, the mother of John Cronin, is well known to the authorities of Hartford. She has been a drinking, troublesome woman during her long residence in and about Hartford and was surrendered to the authorities by her brother, Thomas Callahan, after he had endured her boisterous and wild ways, while under the influence of drink, as long as he could. She is now an inmate of the almshouse in this town, where she has been for nearly five years.

This brief sketch of Cronin's ancestry shows that his father and mother were both inebriates, an uncle and aunt were insane, and a half sister is a drinking, epileptic degenerate. Of the direct stock of his father, John Cronin, was the last, and of his mother the worst descendant.

In these facts a very clear history can be traced of what is well known as alcoholic insanity of the imbecile and epileptic class, the prominent symptoms of which are a marked degenerating heredity, usually from an alcoholic, insane or idiotic ancestry, or practically from a dying family, where the race stock is exhausted, enfeebled and approaching extinction. Alcoholism in such a family is a symptom of progressive degeneration. The drinking is always followed by insane, epileptic and impulsive conduct. When not drinking, apparent sanity and normal conduct may be the rule, but the strain of alcohol on a defective brain will bring on homicide, suicide or epileptic explosions. The use of alcohol is always followed by delirious conditions, delusions and strange unusual acts.

Failures of memory are common symptoms, and may be total or partial. After a time a progressive palsy of the higher brain functions appears. In most of these hereditary defects this moral palsy and loss of consciousness of right and wrong, of duty and obligation, is an inheritance which the use of alcohol develops. All such cases show this strange indifference and unconsciousness of their acts and the consequences. The man's talk and conduct in a

criminal act is only a link in the chain; by itself it may display a cunning, deliberation, mature judgment and recognition of all the consequences, and yet when the other links in the history are known, it will be found to be the act of a clearly insane man.

The act of shooting Skinner with foolish boasts and general conduct, noted by great coolness and indifference, is a good illustration. What he did and said at this time and the impression he created on the minds of persons about him, is a small part of his history, and when judged alone may be very misleading, but taken in connection with all the facts of his life, points out the real condition of health or disease. It is evident that Cronin's mental condition at the time of this homicide must be judged from the facts of his inheritance, from the facts of his surroundings and manner of life, also from his conduct and acts when sober and drinking, and from all the circumstances and conditions which have been influential in his history.

The State assumed that Cronin had a low criminal brain, capable of deliberation and premeditation, and with power of control. That he could reason clearly concerning his acts and their consequences. That in the crime he displayed malice and revenge and full consciousness of the nature of this act, and the legal penalties.

That he was not only conscious of his conduct, but had the power of control and concealment, to take advantage of favoring conditions. That he has been and is of sufficient mental capacity to distinguish between right and wrong in the abstract, and and at the time of crime was of sound mind. That his claims of no memory of the act, and cool indifference, are mere subterfuges for concealment.

The fact of his periodical intoxication and drinking the day before the crime, were assumed to be aggravations and additional evidence of his responsibility.

I urged that Cronin could not have a sound brain, that his twenty years of drinking had so fixed and intensified the inherited defects that he could not reason or discriminate soundly. That in some respects his conduct would be automatic, where the motives and conditions of living were the same, but change these and his disease would be seen. Also, he had "a defective brain showing great disturbance from the use of alcohol, would always be swayed by morbid impulses of any form, and crime, suicide and other abnormal acts would be the rule and not the exception."

Many authorities have pointed out the evident unsoundness of degenerative neurotics, who were alcoholics of long standing. The acts of such persons are always open to suspicion and where crime is committed there is always a doubt. Unusual strange conduct can only be explained on the theory of brain degeneration and disease. While it may lack many of the symptoms of so-called insanity, it will nevertheless show degrees of palsy and brain disorder which can not be mistaken.

This case was argued in all the courts and decided against the prisoner, and finally the Board of Pardons declared him sane, and Cronin was hung Dec. 19, 1894. He maintained the same stolid indifference to the last, sleeping soundly up to a short time before the execution.

The second case was tried at Norwich, Conn., in May, 1894, and was that of Michal Donovan, who

shot and killed John Bell some months before. Donovan was a laborer in charge of a stationary engine, 45 years of age, and a man of quiet peaceable character. He was married and had a grown up family, and was a retiring, hard working man. For five years he had used spirits to excess at irregular times and intervals and was always silent and stupid when drinking, never quarrelsome or violent. During the year 1893 Donovan had drank more than usual, and been stupid nearly every night. In December of that year Bell, a colored man, had called him insulting names and was very abusive for some supposed slight. At this time Donovan paid no attention to this, saying he was not worth noticing and appeared to be in no way disturbed by Bell's insults. Two days after he took an old revolver to a shop to be repaired and loaded, telling many persons he was going to shoot Bell. He drank several times and showed the revolver and affirmed that he was going to find Bell and kill him. This he did in a short time and without any words or apparent excitement, finally, he shot at Bell and finding that he staggered and fell, fired his pistol in the water, and replaced it in his pocket. Quietly walking back, stopping to drink at two saloons, telling the barkeepers that he had shot Bell, he went home, changed his clothes, and walked over to the station house giving himself up. That night and the next day he suffered from delirium and delusions and was treated as suffering from a mild attack of delirium tremens. He soon after recovered and denied all recollection of the crime. From this point on to the time of the trial he was quiet, indifferent and seemed not to be interested in anything and only manifested emotion when visited by his family. When examined in jail he seemed to be dull and although in fair physical health, was strangely indifferent to the results of the trial. Expressed sorrow for having killed Bell, but did not remember the facts of the crime, and seemed to be unconcerned. He could not give a connected account of the difficulties which led up to the crime, and the suspected motive for shooting Bell, who had threatened to have him turned away from his place of work. His mind seemed confused as to events and his own conduct for some time past. In the history of his family an uncle on his mother's side became insane in middle life and was confined in an asylum until death. Donovan had been a moderate drinker up to about 40 years of age, when he began to have distinct drink paroxysms. These increased in frequency and duration until finally he drank steadily every day. The past six months he drank almost every hour, and was many times unfit for work. He complained of his head feeling bad and said he was "not right" dating from the time of an injury from a fall from a wagon. In a conversation with the medical experts for the State, two days later, he described the act of killing, denying that he had said he was going to kill Bell, and in a disjointed way explaining why he had shot Bell. His statements were opposed to the testimony of other witnesses, and seemed to be based on the history of the crime as repeated by others to him. Two medical experts swore that he was sane at the time of the crime and was conscious of his acts and their consequences. The two experts for the defense affirmed that it was a clear case of alcoholic imbecility and unconsciousness of acts, and nature of the crime, and that at present he was of a low order of intelligence, with un-

sound degenerative brain. They further urged that the cool preparation for the crime and telling what he was going to do, committing the act in broad daylight where he was seen by others, was clearly insanity. Such conduct following excesses in the use of drink, could not come from a mind sane and conscious of the acts committed. The counsel for the defense, Messrs. Hull, of New London, and Thayre, of Norwich, urged that there was more than reasonable doubt of the soundness of the prisoner's mind at the time of the commission of the crime. Also that his excessive drinking before the crime would of necessity so impair his reason and judgment that any unusual acts would be more or less insane and be committed without conscious reason. They urged that this crime in its boldness and strange premeditation and execution, and his delirious condition after, was strong proof of insanity. The experts for the defense affirmed that the man at the time the crime was committed was suffering from alcoholic dementia, and when confined had an attack of delirium tremens, from which he recovered with an enfeebled demented brain, and at present is in a low parietic condition.

The verdict was manslaughter and imprisonment for life. This was a rational modern disposition of the case.

Both of these cases were alike in the well marked evidence of imbecility due directly to alcohol. In the Cronin case, the heredity intensified and made the degree of degeneration very clear, and placed the assumption of insanity and unconsciousness without power of control, beyond all possible doubt. In the latter case, Donovan's conduct before and during the commission of the crime and after, clearly indicated the impossibility of mental soundness. Neither of these cases were able to reason rationally, or to form motives and to act upon them with reasonable consciousness of their import and consequences.

The hanging of Cronin ignored all modern facts concerning the brain and its disorders, and was a reversion to the theories that prevailed two centuries ago. Donovan's sentence recognized the dawn of a new era in jurisprudence, and progress along the lines of development, with clearer conceptions of the relations and limits of responsibility.

### BLISTERING BY SUGGESTION.

Read before the Chicago Academy of Medicine, Jan. 11, 1895.

BY H. C. B. ALEXANDER, M.D.

CHICAGO.

As early as 1840 Dr. Lewis Prejalmini with "magnetized" paper produced the effect of cantharides. As Bjornstrom remarks, suggestion not "magnetized" paper caused the blistering. Bjornstrom demonstrates that, by suggestion, congestion may be produced, carried to raised swelling of the skin, to a blister like that of cantharides, to bloody transudation and even to complete formation of a wound. Charcot and his pupils thus produced all the phenomena of burns. Beaunis hypnotized a susceptible subject, told her that upon awakening she would have a red spot under her forearm which he tapped slightly but so as to avoid redness from pressure. Ten minutes after awakening there was evident redness at the place touched which increased in size, was visible about twenty minutes and then gradually disappeared. By suggestion Beaunis could cause the

mark to remain forty-eight hours. Facachon informed a hypnotized susceptible subject that a topoalgic spot would be blistered by cantharides. The next morning pain had vanished and blebs full of serum were present. He cured a right clavicular topoalgia in the same subject by suggestion, during hypnotization, of an actual cautery with the seeming result of a burn. The experiments of Charcot and his pupils in the same direction have had almost identical results. Beaunis made several experiments on Facachon's subject. May 12, 1885, she was hypnotized at 11 A.M.; on her back at a point unreachable by her hands, a strip of eight gummed stamps was fastened. A similar strip had been eighteen hours on another arm without effect. Over these a compress was placed and the subject thrice told that cantharides had been used. She was closely watched during the day and hypnotized at night with instructions to awake at 7 P.M. At 8 A.M., Facachon removed the compress in presence of Bernheim, Leibault, Leigeois, Beaunis and others. When the stamps were removed the underlying skin over about five centimeters was thicker, yellowish, white and inflamed but without blistering. Half a centimeter of surrounding skin was intensely red and swollen. The spot was covered with a dry compress; three hours later the spot had the same appearance and was photographed one hour thereafter. The photograph showed about five blisters. They increased, secreted serum and later suppurated. Later, the arm of the same subject was blistered in like manner.

Another subject suffered greatly from topoalgia. Facachon blistered her by suggestion, below the left ear and on the left temple. Facachon made cantharides inactive in the first subject by suggestion. Having by experiments on a second person, determined that his cantharides blister was active, he used two of the three parts of the same blister on his subject. The third part had been applied with due effect upon a patient needing counter-irritation. The subject was hypnotized; one piece of the same plaster placed on the left arm and the other on the right. The subject was told that the left arm would not blister, while the right would. Nine hours later when the bandages were removed the left arm was normal, the right blistered. My own case occurred in an hysteric in whom the neuropathic element was partly the result of environment. One evening a cutting from a roll of belladonna plaster was placed over a topoalgic spot on the neck. The same roll of plaster had been used on other patients without dermic effect. A decided blister, however, appeared under the plaster. At the outset while the possibility of untoward effects was taken into consideration, it was thought more probable that the blister was due to auto-suggestion, as the patient believed that the object of the plaster was to blister. The blister healed rapidly under lanolin dressing and suggestion. A control experiment was made. Cantharides was applied about 9 P.M., on a new topoalgic spot of which the patient complained without effect; the patient having been assured that it was simply a pain curing plaster. The spot remained free from redness until about 9 A.M. the next morning, when an incautious remark of the nurse led the patient to surmise that a real blister had been applied, and in an hour, wheals followed by vesicles appeared and disappeared. The patient had been meanwhile informed that the nurse

had unadvisedly used the term, blister. The cantharides plaster was carefully tested before being used. The chief value of the present case lies in its control experiments. The patient, while obviously in a condition extremely susceptible to suggestion, at no time was in the true hypnotic state.

These cases and those in which bleeding occurs at written points in dermatographic subjects, explain the cases of stigmatization which from time to time appear in religious communities and of which the latest case was reported by Dr. M. F. Cooney as having occurred in Kentucky. In many of these cases the influence of suggestion is evident, from the fact that the side wound of Christ occurred on the right side in lieu of the left, because of the ignorance of the stigmatized subject.

### THE NON-TOXICITY OF UREA.

BY R. HARVEY COOK, A.M., M.D.

ASSISTANT PHYSICIAN OXFORD RETREAT, OXFORD, OHIO.

Urea being the final product of tissue metamorphosis and apparently playing no rôle whatever in our economy, it was natural to consider it a waste material, of which our system should rid itself. Finding this material diminished in various affections it was *a priori* considered that the system must be overloaded with this effete material, urea.

That urea is even yet considered a toxic body by many, is apparent from the numerous articles attributing toxic effects to this substance. The recent article by Dr. J. Nelson Teeter, on "The Relation of Urea to Epilepsy," which appeared in the January number of the *American Journal of Insanity*, has caused me to write my observations and experiments in regard to the toxicity of urea.

Perhaps no one has done more toward fathoming the mysterious depths of auto-intoxication than has Bouchard; to him my experiments are due, nor do my experiments differ from his, but prove to my satisfaction that his conclusions are justifiable, *i. e.*, that urea is not a toxic substance—or rather is not toxic in the quantity found in any known pathologic state.

My first experiment was to inject into the vein of a rabbit weighing 1.247 kilograms, 2 grams urea in fifty c.c. water. The animal showed neither stupor, somnolence nor convulsions. Since the solution was injected directly into the vein, it was not possible for the urea to have been eliminated as rapidly as it was absorbed. Supposing 1 kilogram of animal to form .4 grams urea—which is the amount normally ascribed—this animal would normally have formed in twenty-four hours only .498 grams, but we injected 2 grams which is four times the amount formed in twenty-four hours; this animal could have retained the entire amount of urea formed in four days and suffered no ill effects. Accordingly, man could retain with impunity four times the amount of urea formed in twenty-four hours. Since he forms say 32 grams per diem, we would have  $32 \times 4.128$  grams, which is over four ounces. The conclusion must then be that the various phenomena attributed to the poisonous effects of urea are not due to the same, but probably some other body.

I have repeated the experiment, with some increase in the amount of urea, and find in order to kill 1 kilogram of animal it is necessary to use 6 grams of urea. A man of medium weight, say 60 kilograms, will then

require 360 grams to produce death. A man of this weight should form 24 grams urea in twenty-four hours; but we have shown it would take 360 grams to poison him, which is fifteen times more than he forms in twenty-four hours; therefore that his death should be due to retention of urea, he would have to retain the entire amount of urea fifteen days. These experiments show conclusively that urea, contrary to what is generally believed, is but feebly toxic.

In double calculous obstruction, uremic (so-called) accidents occur on the second or third day, but according to the above observation, the person has formed at this time only one-eighth of the amount of urea necessary to cause death.

According to Bouchard, urea is a diuretic. While, then, this product of disassimilation causes the kidney to secrete, it not only makes its own escape, but likewise removes other waste material from the system. In cases of hepatic uremia, where there is not sufficient urea, or in cases of some pathologic state of the kidney, upon which urea can no longer act, we find as a result a diminished amount of urea, and as a result of this deficiency of nature's diuretic, an overloading of the system with various other substances; and to these we must look as the cause of intoxication.

Although urea in itself is not a toxic body, the value of a quantitative estimation of urea is not to be lost sight of; for since this is the substance which forces the renal barrier, it necessarily follows that if the urea be diminished we must find other waste material diminished in proportion, thus making the quantity of urea a criterion, to a certain extent, of the toxic matter retained within the system. I have under observation cases of insanity undoubtedly caused by an auto-intoxication, in which the urea is at times reduced to 9 grams per diem, this showing to my mind that the toxic materials are retained in the system in some proportion at least to the urea.

### A NEW OPERATION FOR THE RADICAL CURE OF HEMORRHOIDS.

BY N. H. HENDERSON, M.D.

SURGEON TO LAKESIDE HOSPITAL,  
CHICAGO.

A few years ago the surgeon who had before him a case of hemorrhoids found himself between the devil of ligation and the deep sea of the actual cautery. But in the great "onward march" of surgery this particular field has not been overlooked, and to the specialist there are few cases not amenable to some form of treatment.

When Dr. Whitehead gave to the profession the "Whitehead operation for the radical cure of piles," much was said for and against it. Then Dr. Pratt introduced the famous "American operation." Both are too familiar to require description, and both have much to recommend them, as well as much that invokes criticism. It would seem that in the simple operation of destroying a few hemorrhoids, there would be little room for difference of technique, yet how often a slight change in the *modus operandi* will simplify and render easy a once difficult problem, at the same time giving better results.

It is my purpose to describe an operation, which, by virtue of its simplicity, is preferable to either the Whitehead or the American, in cases where either of the latter are indicated.

The patient is prepared as for any operation on the rectum, by giving liberal cathartics twenty-four hours previous, followed in twelve hours by a copious enema, light or perfectly liquid diet for twenty-four or thirty-six hours before the operation. When on the table, wash out the rectum and dilate thoroughly with a large speculum. Now seize the hemorrhoidal tissue at different points of its upper boundary with "T" or the ordinary hemostatic forceps, as in the American, by slight traction, everting the entire circumference. Next, divide the tissue at the junction of the mucous membrane with the true skin, encroaching as little as possible upon the integument. Dissect the hemorrhoidal tissue from the sphincter, being careful not to injure the muscle at any point. Having carried your dissection up as far as the hemorrhoids extend, remove the loosened tissue completely, catch up the bleeding points and, if necessary, tie them. If we were to stop at this point, we would have so much contraction of the parts when they had healed that the patient would be in a worse condition than before the operation, just the condition that is many times presented after the Whitehead or the American operations. To obviate this difficulty we will go a step farther. Again put the sphincter on the stretch and before removing the speculum, make a free incision in the posterior median line to the extent of dividing all of the muscular fibers, and with the scissors trim away each edge of the wound, so that they will not roll together and immediately unite. We now present a complete section of one-half, three-fourths, or possibly an inch of the lower part of the rectum with the sphincter and laid bare and a deep wound in the posterior median line. We will now place within the rectum a moderately large cotton tampon with a strong double silk thread attached, loosen the integument a little to permit the skin to pass a little way into the anal orifice rather than drag the gut out. Now by making traction on the threads attached to the tampon we cause the bowel to descend, and by packing with gauze the posterior incision, we prevent its healing except by granulation. Now place outside a small roll of cotton covered with gauze to which the tampon threads are to be firmly tied. Thus we get an equal pressure from within and without, in most cases completely approximating the edges of the bowel and the skin. In twenty-four hours there will be sufficient union to retain the parts in their proper relations, at which time the tampon is to be gently removed, the packing taken out of the wound in the sphincter and the entire wound irrigated. Then repack the wound in the muscle and apply any dry dressing preferred. If dressed daily in this manner, being careful to keep the incision packed until it has filled in by granulation, and the space between the membrane and the integument healed, as it will, either by first intention or by granulation, you have as a result a normal rectum, capable of performing all its functions in a normal manner. In thirty-six hours after the operation give a laxative, followed in twelve hours by an enema, and see that the bowels move daily afterward. The advantages this operation offers over the Whitehead and the American are the same, inasmuch as the two are identical, with the exception that in the American the dissection is from above downward and in the Whitehead the procedure is reversed, the object in both cases being to remove the pile-bearing portion and unite the mucous membrane and the integument.

If you will take the trouble to examine a few cases that have been operated upon by either of the above methods you will find that, even as long as one to two years afterward, there is a band of cicatricial tissue entirely encircling the anus, where the stitches have been, feeling very much like a wire, and which stiffens the muscles so that absolute control is impossible, a state of affairs which must be experienced to be fully appreciated. While this is not the inevitable consequence of these operations it is true of a vast majority of cases. We also know that it is necessary to continue to dilate the sphincter for weeks or even months after these operations, in order to prevent such a degree of contraction as will leave the patient a prey to insomnia, constipation, dyspepsia, nervous debility, etc.

Then again the stitches almost invariably slough out, leaving a gaping and suppurative surface instead of a clean healthy one, as in the case where no stitches are used. I assert that in stitching the gut to the skin the parts are thrown so far out of their normal relations that they will never have their normal action, but approximate them by a moderate pressure, as I have suggested, and nature will make allowance for the tissue that has been destroyed. The feature of this operation is the posterior incision, which, filling in by granulation, allows for the contraction which follows. My personal experience leads me to give this method the preference over the clamp and cautery. With the latter, it is impossible to make a complete section of the hemorrhoidal region, and those of us who have had experience and an opportunity to watch results, find that no cases are so prone to recurrence of the trouble as those having been treated with clamp and cautery.

As for the practice of tying off large masses of tissue, and leaving the stumps to slough away, thereby exposing the patient to danger of sepsis from absorption, we can only marvel that anything so unsurgical and so cruel has ever been countenanced by the profession. But the ligature has had its day and may well be relegated to the curio shops, where it will rank with the rack and thumb-screw of Inquisition days. We hope that none of our readers are so antiquated in their ideas that the remarks on ligation can be accepted as personal.

#### ORIGINAL INVESTIGATIONS ON THE NATURAL HISTORY, (SYMPTOMS AND PATHOLOGY) OF YELLOW FEVER. 1854-1894.

BY JOSEPH JONES, M.D., LL.D.  
NEW ORLEANS, LA.

(Continued from page 245.)

#### CHAPTER V.

It will be observed that Dr. Dowler records three cases in which in the primary stage of yellow fever, the temperature of the axilla reached 106 degrees; one 106.5 degrees, and one 107 degrees; in the middle period, one case 106 degrees, two cases 107 degrees, one case 108 degrees, one case 108.5 degrees, and one case 109 degrees; and notwithstanding the high temperatures the patients recovered. The patient whose temperature reached 108 was cured in seven days; the one with a temperature of 108.5, was convalescent on the third day; and the third with the axillary temperature at 109 degrees, was

cured in twelve days. The highest temperature observed by Dr. Dowler in fatal cases of yellow fever was 110.5 degrees axilla. On the other hand, by boldly exploring the regions of the body, a few moments after death, Dr. Dowler has shown that the temperature of the deep-seated muscles of the thigh may attain a temperature of 113 degrees F., the epigastrium and rectum 111, and the liver 112 degrees.

There is no proof furnished by the observations of Dr. Dowler that there was an actual increase of heat in the internal organs after death above that which it may have attained during the active stage. All the facts recorded in his tables appear to sustain the view that the high temperatures existed at the same time during life in the internal organs. Thus in those cases in which the temperature of the surface of the body in the region of the axilla reached 110.5 during life, it is probable that the temperature of the internal organs was at least from 2 to 4 degrees higher; and it is worthy of note that in not one of his observations on the post-mortem heat of regions, did the temperature of the axilla exceed 110.5, the highest point reached during life. It is still further worthy of note, that the case in which the thigh gave 113 degrees, the liver 112 degrees, epigastrium 111 degrees, and the heart 109 degrees, the temperature of the axilla was 109 degrees.

My own investigations upon the post-mortem heat in yellow fever sustain the view that there is no actual increment of heat above the highest maximum of the internal organs during life. With the sudden cessation of respiration and of the consequent transpiration from the surface of the lungs, and the sudden suppression of the perspiration of the skin and the consequent diminution of evaporation from the surface, there must necessarily be a change in the distribution of the heat, and as it is diffused by conduction from the center to the circumference, an increment of heat on the dead surface. If, however, this view be incorrect and if there is in certain cases an actual increment of the total amount of heat in the body, after death by yellow fever, such increment is probably due to the following causes: 1, cessation of respiration and evaporation from the surface of the lungs; 2, cessation of perspiration and diminution of evaporation from the surface; 3, the continuance of chemic changes chiefly in the blood and internal organs, and the consumption of the oxygen of the blood for short periods after death, the transformation of certain modes of force, as the nervous and muscular into heat.

To demonstrate conclusively whether there is an actual increment of heat in the body after death from yellow fever, comparative experiments should be instituted by immersing those suffering with yellow fever in definite amounts of cold water, (the quantity being regulated in accordance with the weight of the patient), and noting carefully the temperature assumed by the surrounding water at definite periods. Similar experiments, corresponded exactly in the quantity and temperature of the water employed and in the periods of time. The main element of disturbance to be calculated and as far as possible, eliminated from the first series of experiments would be the effect of pulmonary acts or respiration. In the absence of such exact experiments, the subject of post-mortem heat in yellow fever and other diseases must necessarily be involved in obscurity.

Dr. Dowler, however, inferred from his experiments

that there was an actual increment of heat in the body after death from yellow fever, and the views of this distinguished observer and physiologist are worthy of the most careful consideration. Thus in commenting on the results of his investigations he says:

"The average of five *maxima* of the epigastrium are nearly the same; but if we select ten *maxima* from each of these regions, the thigh will be found the hotter of the two by 0.3 degrees. This is the more remarkable, as the observations were made, owing to the emergencies incidental to an epidemic, at irregular, sometimes at lengthened periods after death, when the thigh more especially, from its comparative smallness, and greater exposure, had parted with more or less of its morbid caloric, by contact and radiation.

"In one series of cases of yellow fever, taken without selection, the following results were obtained: Fifteen patients who recovered, when temperatures were taken at a period which averaged fifteen and one-third hours, after the invasion, and afforded a mean temperature of the hand of 101.8, and for the arm-pits 104.84 degrees; nine persons who died, gave at an average of twenty-two and one-third hours after the invasion—for the hand 103.62 degrees; for the arm-pits 105.44 degrees.

"The maxima of these classes coincided, but not the minima. In those who died the average was higher; in the hand, the maximum reached by both was 107 degrees; the minimum in the hand among those who recovered, was 95 degrees, and of those who died 99 degrees; the maximum of the former in the axilla, 107 degrees; of the latter 109 degrees; the minimum of the former in the same region, 102 degrees, and of the latter 100 degrees, the latter being *in articulo mortis*.

"The extraordinary fact that in some bodies recently dead, the temperature, at various periods thereafter, rises higher than it had risen during any stages of the maladies which preceded—much higher than in the latter stages—has been fully confirmed, as well as another, still more extraordinary; namely, that at uncertain periods, usually, perhaps less than an hour, though occasionally later, the center and periphery will attain to, and remain at a stationary, perhaps a high temperature, which, for a considerable time will neither rise nor fall. But, still further than this, either the center or circumference, or both together, having reached a certain temperature, will sometimes fall and rise several degrees, repeating these movements several times. These internal and external fluctuations may or may not coincide in time, degree, and duration. Assuming that these thermal currents originate in different regions, independently of each other, and pursue different, perhaps curved routes, occasionally uniting at certain points or foci, it might be expected that at these points of contact or convergence the maximum heat would be found. These foci are not found in a marked degree, even in the center of the brain, far less in the inferior extremity below the knee, when the calorific power is most feeble or null in cadavers.

"How hot soever the patient may have been during the progress of fever, the heat generally recedes before and at death; and this recession will, upon averaging a great number of cases approximate natural standards, at least in the arm-pits and some other accessible regions.

"The development of post-mortem calorification

does not appear to be materially accelerated or retarded by the atmospheric temperature, humidity, or dryness. This heat is not the effect nor the accompaniment of, but antagonistic to putrefaction. When calorification ceases, physical refrigeration begins; and when the latter is reached, putrefaction is rapidly developed, if the weather be sufficiently warm.

The laws of post-mortem calorification are numerous and complex. Its increment, decrement, degree, duration, and repeated ebbings and flowings, differ in different bodies, so much that neither physics nor physiology has as yet furnished any satisfactory standard explanation but a parallelism. Periodic diseases, in which paroxysms of cold and heat alternate, seem to indicate analogy, if not identity, as do the great but little known fluctuations of the normal temperature during morning, noon, evening and night, among persons in health." (*New Orleans Medical and Surgical Journal*, March, 1860, Vol. XVII, pp. 210-212.)

In the May number of the same journal, in which Dr. Dowler continues the subject, he remarks:

"Both physiology and pathology furnish abundant evidence that animal heat is due neither to pulmonary combustion, nor in any way attributable to the energy of respiration. For example: In solar asphyxia (sunstroke of the first degree), which is almost always quickly fatal, respiration is very imperfect, being restricted chiefly to the bronchii and trachea, and is attended with loud mucous rattlings (râles); yet this is the hottest of all diseases. As the suffocation, I might say strangulation, increases, so does the heat, which in a few minutes reaches in some cases, 112 degrees F. in the axillæ and other regions. The post-mortem heat is equally remarkable, and may be of very long duration. The lesion usually found being either extravasation into the pulmonary tissues or congestion, which illustrates the previous history of pulmonary embarrassment.

"In sudden apoplexy (*apoplexie foudroyante*), as well as in most cases of apoplexy, coma occurs, and as the coma increases, the heat increases and is very persistent after death. Generally, in cases of the comatose form of death from acute diseases, particularly fevers, the close of life is attended with comparatively high temperature, notwithstanding the embarrassment and infrequency of the respiratory act."

"Whether the pulmonary congestion be the primary or secondary condition of insolation, I will not say; but I must remark, that of all morbid appearances of a congestive character, this is the least equivocal, so far as I have examined."

Although physiology teaches us that man is endowed with the power of maintaining the same heat of his body in all climates and all situations, with few exceptions, still it is possible, under peculiar circumstances, that the body may become actually heated beyond the normal standard. A chemico-vital refrigeration by means of perspiration or evaporation, is constantly going on. 'The fire kings,' themselves, when in a heat of 500 or 600 degrees, would roast and turn to cinders were it not for this refrigerating process, in conjunction with a vital energy which for a time neutralizes the accumulating power of caloric. The solar heat in sunstroke probably accumulates upon the surface (and in the lungs), of the body faster than nature can refrigerate through the lungs and the skin by evaporation; the vital energy being exhausted by the contest as well as by the excessive

labor (in most cases), is unable longer to neutralize the excess of temperature; vital chemistry is unequal to the task of preventing the conduction of heat into the body, and death is the consequence."

"If we suppose the central, the great vital organs to be as hot during life as they are found to be after death, the only wonder is that vitality should maintain its seat for a week or more, under the positive changes that ought, by every law of calorics, to take place in the molecular arrangement of the tissues. Let us suppose the brain in life to become as hot as the thigh is found to be after death, that is 14 or 15 degrees F. in health; the cerebral mass would expand faster than its cranial walls; the fluids would dilate and perhaps transude; compression would be the consequence, attended with convulsions, coma, and other effects incompatible with life. Suppose any other organ should become such a focus of morbid caloric only for a moment, would not each vessel from dilatation lose its healthy elasticity and cohesion and thus pave the way to sanguineous congestion? In some diseases, the lesions will afford an average alteration as great as fatal gunshot wounds; as, for example, dysentery, consumption, cancer. But in a fever how much is unexplained! Is not morbid caloric the agent that eludes the knife of the anatomist? To say nothing of its directly poisonous, let us consider its mechanical effects as above mentioned upon the brain. After dilating its delicate vessels, and establishing a sanguineous congestion death follows. The brain, as we have shown, falls sooner than other central parts under the law of refrigeration; the cranium contracts; this tremendous force drives the blood down from the brain towards the warmer and more yielding centers of the trunk; perhaps a real apoplexy, without rupture has disappeared."

So far as morbid heat can be identified as a cause of disease, we deal with a positive, not an imaginary agent, where the ground is not eternally slipping from beneath our feet. Albumen, which abounds in the brain and fluids, coagulates at 160 degrees; hematoxin, the coloring matter of the blood at 149 degrees; and moderate increase of heat vastly augments the solvent powers of the serum over gelatin, so abundant in the body. The phosphorus of the body were it uncombined, would burn in a heat less than 113 degrees.

"Admitting that the whole body be permeated with 10 or 15 degrees of heat, and that it can not render this heat latent, I ask again, is it wonderful that death should ensue? Which atom has not undergone a deleterious modification, or a new arrangement in its chemic, mechanic and vital relations? Delaroche and Berger prove that animals in chambers heated to 120 or 130 degrees F., have their temperature raised 11 or 16 degrees, and die speedily. If, as some maintain, all lesions may be reduced to those of nutrition, caloric is an agent well adapted to play an important and fundamental part, not only diminishing the elementary cohesion of the tissues, but in debilitating all the organs, thereby favoring intertextural depositions, hypertrophies, softenings, hemorrhagic serous effusions, morbid secretions, engorgements, and other alterations, solid, liquid and gaseous." (*New Orleans Medical and Surgical Journal*, May, 1860, Vol. XVII, No. 3, pp. 368-372; *Western Journal of Medicine and Surgery*, April, 1843; *New York Medical Gazette*, Vol. I, p. 209; *New York Journal of Medicine*, 1846.)

The researches of Dr. Bennet Dowler established

the important fact that post-mortem heat was not confined to yellow fever, as will be seen from the following cases recorded in his articles on "Animal Heat." (*New Orleans Medical and Surgical Journal*, Vol. XII, 1856, pp. 205, 289, 433, 470, 603, 759):

"Case 1.—Apoplexy, post-mortem heat; E. F. D., aged 46; born in France; for many years residing in New Orleans; stout and fleshy; long a sufferer from strictures and retention of urine; would allow neither the catheter nor the sound to be applied. About a month after my attendance upon him for an attack of acute pneumonia, he was seized in the night with a chill and fever; after rising from his bed in the morning, he fell and instantly expired; in thirty minutes after which, the axilla gave 102 degrees; in ten minutes 105 degrees, continuing stationary twenty-five minutes; in five minutes 104.5 degrees; in five minutes 104 degrees, remaining stationary ten minutes, that is as long as observed. A partial post-mortem examination brought to light a stone in the bladder of enormous size."

In this case it is evident that Dr. Dowler made no observation of the temperature at the moment of death. The rise in the temperature of the axilla may have been due to the equalization of temperature after the arrest of cutaneous and pulmonary transpiration and evaporation. In this case the unknown element upon which the entire theory of the post-mortem increment of heat rests is the temperature of the internal organs and especially of the blood in the large vessels just before death. No such objections can be urged against the observations in the following case which appears to sustain the conclusion that there was a marked increment of heat immediately after death:

Case 1.—Chronic enteritis, with pulmonitis; post-mortem heat. Aug. 18, 1843; room about 80 degrees. M. H., a woman aged 30, sick about sixty days; dead two hours; greatly emaciated; an incision three inches long in the umbilical region, admitting the air freely; temperature in ten minutes, 102 degrees; in fifteen minutes, 104 degrees; in twenty minutes, 106.5 degrees; in thirty minutes, 104 degrees; heart in 20 minutes, 104 degrees; in twenty-five minutes, 104 degrees; in thirty minutes 104 degrees, and slightly declining; right lung infiltrated with pus, gave in ten minutes 102 degrees; thigh 100 degrees.

Case 2.—Typhus; post-mortem heat. Feb. 28, 1848; air of room about 65 degrees. Mrs. —, aged 26, born in Ireland, last from New York; resident two months; sixteen days sick; dead twenty minutes. Axilla 100 degrees; in five minutes, 101.5 degrees; in ten minutes, 101.5 degrees; vagina in five minutes, 107 degrees; in ten minutes, 107.5 degrees; one hour after death, 107½ degrees; fifteen minutes later at dark, when the experiment ended, 107¼ degrees.

Case 3.—Typhus; post-mortem heat. July 22, 1845; air at 5 A.M., 76 degrees; at 5 P.M. 94 degrees. A. F., a Swiss, aged 30, last from Havre, ship *Swanton* fifty-one days at sea; died the second day after landing; experiment begun twenty-five minutes after death, and lasted without interruption two and one-half hours, having been stopped by the funeral. At intervals the axilla gave 109 degrees, 110, 110.5, 110¾ degrees; rectum 111.5 degrees; epigastrium 109; left hypogastrium 110; right hypogastrium 110.5; iliac and umbilical 110 degrees.

Case 4.—Typhoid pneumonia with pericarditis-hepatization. May 2, 1844, thirty minutes past noon; air about 80 degrees. P. M., aged 35; sick eight days; hand 90 degrees; bend of the arm 99; axilla 104; popliteal region 99; died five hours after; remained in bed fifteen minutes, and then as long in the dead house, covered with a linen sheet only; thirty-five minutes after death the axilla 104 degrees, and the popliteal 100; in five minutes axilla 105; popliteal 101; in five minutes axilla 105.2; popliteal 101; in five minutes axilla 106, popliteal 101.5; bend of arm 101; rectum in five minutes 100; bend of arm 101; in five minutes groin 102; bend of arm 100; in 10 minutes groin 100; hand in ten minutes 100; rectum in five minutes 106; axilla in five minutes 108 degrees nearly.

The following observations were made in the order in which they stand, at intervals of one, two, three or more minutes: Rectum, 108.5; axilla, 101; rectum,

109.5; axilla, 101.5; rectum, 110.5; axilla, 102; rectum, 110.5; axilla, 102. The observations lasted about an hour and a half, and were stopped by the lateness of the evening, at about two hours after death, the air being then about 79 degrees. Brain seventeen hours after death, 83; center of the thigh, 89; air, 83. Putrefaction odor absent at twenty-two hours after death. Here the axilla attained a maximum of 108 degrees, nearly one hour and a half after death, exceeding that of the living state 4 degrees, as taken four and one-half hours before death, exceeding that of the dead subject thirty-five minutes after death by the same number of degrees. A still greater contrast is found in the palm. The rectum rose from 100 degrees in an hour to 110.5 degrees after death, to the maximum of 110.5 degrees at twenty-five minutes later, and was stationary afterward, having gained and retained 10.5 degrees; while the axilla gained 4 degrees, lost 7 degrees and regained 1 degree, when night approached preventing further observations.

Case 5.—Congestive fever; post-mortem heat. Aug. 28, 1848; room 88 degrees. A. F., born in Maine; resident six months; aged 35; sick seven days; dead forty-five minutes; axilla in five minutes, 108 degrees; in five minutes 108.5; in five minutes 109, when the experiment ended.

In the majority of cases of cholera observed by Dr. Dowler, there was after death a progressive refrigeration from the surface toward the center. He records, however, the following case in which there appears to have been a marked increase of heat after death.

Case 6.—Cholera; post-mortem heat. In Aug. 24, 1848; air of the house 78 degrees. H. P., Swiss; dead about thirty minutes; each experiment being consecutive, lasting about five minutes in the following order: Axilla 104.5 degrees; 105.75; tongue 98; rectum 108; 106.5; 106.33¼; 108; 108.5; 109; epigastrium 108; 110; 110.5; brain through the nostril 103; concave surface of the loin 108; heart 109.5 brain 102.5; abdominal cavity 108; concave surface of loin 109; rectum 103.5. The experiments ended about two hours after death.

Case 7.—Solar asphyxia, coup de soleil, insolation, ictus solis, sunstroke. July 24, 1845; a day of extraordinary heat; air at 6 A.M. 80 degrees; noon 93 degrees. Deaths from sunstroke officially reported ten; unwritten and misnamed by estimation five; total fifteen. G. F., born in Boston; aged 28; some minutes before 6 P.M., fell while at work at the corner of Camp and Julia Streets; thirty minutes after, the experiments began; for twenty minutes, during the agony, the armpits gave 111 degrees; eight minutes after death 112; in fifteen minutes 112, in twenty minutes 112.5; at about 7 P.M. 113. The body was then stripped, laid in a cooling house, exposed to a free circulation of air, and was dressed in a muslin shroud. The axilla had been in the meantime freely exposed, but gave at seven hours and twenty-five minutes 112 degrees; seven hours and thirty-five minutes, 112; at seven hours and forty minutes, 112; at seven hours and fifty-five minutes, 111.5; at eight hours and thirty minutes, 111; at eight hours and forty-five minutes, 110.25; at nine hours, 109.25; at nine hours and fifteen minutes, 109, when the observations ceased.

Dr. Dowler gives the following as his observations of the temperature of this unexampled day: At 6:30 A.M., 84 degrees; at 8, 75; at 7:30, 87; at 8, 88; at 9, 90; at 10 A.M. in the sun near a wooden wall, 115 degrees; touching the same, 130; at 11 A.M. sand in the street, 143 degrees; at 2 P.M., sand in the street, 152 degrees; roof of a house, touching, 150 degrees; at 8:30 P.M., 89 degrees. River at 8 A.M., 83.75 degrees; at 3 P.M., 84.5 degrees; in the shade near the sun at 3 P.M., 102 degrees; in the house 97 degrees; at 4 P.M., 96 degrees.

Case 8.—Solar asphyxia in sunstroke, complicated with serous-meningeal apoplexy. Aug. 30, 1848: 11:45 A.M.; dead house 97 degrees. W. C., Irishman, aged 35; resident one

year; ate his breakfast as usual, worked till 9:30 A.M., soon after fell insensible; died 11:20 A.M. Dead twenty-five minutes. The thermometer remained in the axilla fifty-five minutes, without having been changed, as follows: Five minutes, 105 degrees; five minutes, 106.5; five minutes, 108; ten minutes, 108; ten minutes, 108; ten minutes, 108; ten minutes, 108.5; knees, 106; thigh 108; scroto perineal, 108; rectum, seven minutes, 110; fifteen minutes, 110; epigastrium, 109.25; middle of the thigh, 108.75; chest, 107. The small intestines contained from one to two pounds of chyle; thin in and near the duodenum; thick and pasty in the middle and lower third of the jejunum; semi-coagulated but little adhesion; soft clots or flakes of a milky opaline color prevailed in the ileum; in the lower third of the latter, especially near the valve, a point scarcely perceptible here was noticed.

While the above experiments on W. C. were progressing, the veins became greatly distended; a ligature was placed on the arm, a vein was opened, about two ounces of blood filtered out, after which a trickling took place for a considerable time, amounting by estimation to twelve ounces. The circulation was found to be very rapid about the head; the skin of the face and neck were injected, dark, lurid and somewhat mottled; there was no cardiac hyperemia or injection of the dependent parts; the external jugular veins were distended as if ready to burst. The left jugular was opened, as for ordinary blood letting, but no drainage or pressure was used, the head being raised, so that the orifice was nearly on a level with the breast bone. The blood jetted completely without wetting the skin, forming an arch, the diameter of which continued to extend for five minutes; at the end of eight minutes the arch had contracted owing apparently to small clots in the margin of the orifice. Dr. Dowler estimates the amount of blood which flowed out of the jugular vein at five pounds eight ounces. As the blood letting progressed the congestion and discoloration of the skin of the face diminished. Dr. Dowler concludes from this experiment that the circulation in the veins was more active than in health.

*Case 9.*—Yellow fever, intermittent type at its inception, with prolonged coma at its conclusion. Post-mortem heat August 29 1843, air about 83 degrees. S. F., born in Cincinnati; aged 24; sick eight days, (incipient coma); hand 104 degrees; axilla 105. The coma continued until death, three days after. The experiments with one instrument began thirty minutes after death, and continued about two hours. In the order of time as follows, having been recorded at intervals of two, three, five and sometimes more minutes: Axilla, 104 degrees, 105, 106, 106; thigh, 106, 107, 108, 107; axilla 107; left hypochondriac, 109, 109; right 109; hypogastrium 106; thigh 106.5, 106.5; lungs 102; heart 103; thigh an hour after the removal of all the abdominal viscera 106.5, and falling. Weather rainy; room 84. Body exposed to a free ventilation.

*Case 10.*—Yellow fever, post-mortem heat. Sept. 15, 1843; noon, air 89.5 degrees. A. G. G., born in New York; sick four days; hand 91 degrees; axilla 100; I bled to syncope, and cupped twice yesterday. Died at 1 P.M. In five minutes after death the experiments began, and were noted consecutively every five minutes, more or less: Axilla 102 degrees, 104, 106.5, 107, 106; thigh 106.5, 107, 106.5; axilla 105.5; thigh 106; left lung 106; upper lobe 103.5; heart 104.5; hypogastrium 106.5, 106.5; left hypochondriac 105.5; right thigh 106; left 106; axilla 104; left hypochondriac 104; hypogastrium 106.5; right hypochondriac 106.5; thigh 106.5; hypogastrium 106.5; left hypochondriac 104; right 104; rectum 105; hypogastrium 105. September 16, dead twenty-two hours; room 90 (noon); thigh 89; left lung 92; epigastrium 92. Incipient putrefaction.

*Case 11.*—Yellow fever, post-mortem heat. August 22, 1843, room 86. J. H., born in Virginia, aged 30; sick twelve hours, bled twenty ounces; the blood falling on the thermometer placed in a basin, gave in ten minutes 100 degrees; thirty minutes later, hand 103; both axillæ 107; (blood letting repeated) to syncope; cupping same day. August 23, cupped twenty ounces. Died at 10:25 A.M. Experiments

began in ten minutes, ending at one hour and a quarter after death, in the following order: Axilla 100 degrees, 103; perineum 101; axilla 101.5, 101; rectum 103, 103; axilla 103; when the experiments ceased.

*Case 12.*—Yellow fever, post-mortem heat. August 15, 1843. Room 86. P. L., aged 20; sick three days; hand 99 degrees; axilla 104. August 16, hand 98; axilla 103. August 18, axilla 99. August 19, room 90; hand 98; axilla 101. August 20, died.

The observations beginning twenty-five minutes after death, were recorded about every five minutes continuously for three hours and forty-five minutes, with one thermometer, in the order following: Room 86 degrees. Axilla 100, 105, 106.5, 106.5, 106.5, 106, 106, 106.5; groin 104, 103.5; right hypochondriac 109; left 108.5; right iliac 108; left 108; right hypochondriac 108; thigh 109, 109; cardia of the stomach 109, 109, 109; circumference of the left lung 107; mediasternum 107, thigh 107, 107; right hypochondriac 107; left 107; heart 107; hypogastrium 107; thigh 107; heart 107; thigh 108, when the experiment ceased.

*Case 13.*—Yellow fever. Extraordinary heat during life, post-mortem heat. August 23, 1847. J. F., Irishman; aged 28; resident nine months; dying; experiments before death for forty-five minutes; hand 107 degrees; axilla at intervals during thirty minutes 110, 110.5, 110, 110. Died. Axilla at intervals during thirty minutes after death, 110.5; bend of the arm at ten minutes 107. Carried to the dead house, stripped and laid out. Axilla about one hour after death 108; at two hours 107 $\frac{3}{4}$ . Darkness put an end to further experiments.

*Case 14.*—Yellow fever, post-mortem heat. August 28, 1848. Air about 89 degrees. N. L., born in France, aged 23; resident eighteen months. Dying; the hand and the ball of the thumb 94 degrees; bend of the arm 102, and falling; axilla 106. Dead house 89. The experiments began soon after death and continued with intervals for two and one-half hours, in the order following: Bend of arm 104 and falling; calves of the legs brought in contact 100; axilla 107; bend of the arm fifteen minutes 105.5. Stationary; axilla 107, soon 108, continuing for forty-five minutes, then declined to 107 $\frac{3}{4}$ , and in one hour after to 103 $\frac{3}{4}$ .

*Case 15.*—Yellow fever, post-mortem heat. August 12, 1847. H. M., a German, aged 45; hand 89 degrees; bend of the arm 93. Died one hour after. At one hour after death, the experiments were made for a few minutes, having been interrupted by night: Axilla 106, 106 $\frac{1}{4}$ , and rising, being thirteen and one-sixth beyond the living state one hour before death.

*Case 16.*—Yellow fever, post-mortem heat. August 13, 1843. Air 91 degrees. R. C., born in Kentucky; aged 25; sick nine days; hand 98 degrees; axilla 102. Died next day. Room 93. The experiments began thirty minutes after death, and were noted every ten to twenty minutes ending with the seventh hour in the following order: Axilla 106.5; fold of the groin, 109; rectum 111, 111; axilla 104, 104, 104, 104; thighs (in contact) 102; rectum 109, 109, 109; axilla after two hours exposure 100; rectum seven hours after death 102.

*Case 17.*—Yellow fever, post-mortem heat. Sept. 7, 1843. Air 80 to 83 degrees. J. G., aged 32; born in Ireland; sick five days; hand 98 degrees; axilla 102. September 11, hand 99; axilla 104. Died twenty-four hours after. The experiments began ten minutes after death; the body exposed to free ventilation; the room 90 degrees; the axilla ten minutes 109; left thigh five minutes 113; epigastrium five minutes 112; thigh old incision 109; epigastrium 112; right thigh new incision 111. After an interval of one hour the heart gave in eight minutes 109; the thigh in five minutes 109. After the removal of all the abdominal viscera the thigh still gave 109 degrees at about three hours after death. About one hour after death, both the arms including the scapulae and shoulder-joints were amputated for the purpose of experimenting on the contractility of the separated limbs. The limbs and body together discharged from three to four pounds of blood, which did not seem to diminish the heat of the trunk, nor that of the separated limbs, so long as the experiments lasted.

*Case 18.*—Yellow fever, post-mortem heat. August, 1893; air of the room 84 degrees. L. L., aged 25; sick five days (cold for two days before death as in congestion), dead twenty minutes; weather very breezy; body resting on stone floor, freely ventilated; experiments with Reaumur's thermometer (now expressed by Fah.): lasted three hours and forty minutes, that is four hours after death, having been noted every five or ten minutes in the order of time as follows: Axilla 108 degrees; mouth 103; epigast. 108; perineum, without incision, 104; center of the thigh, 108 $\frac{1}{2}$ ; mouth, 99 $\frac{3}{4}$ ; epi-

gast. 108; thigh 106; axilla 104; epigast. 107 and 106½, 106½, 106½. Experiments now ceased for one hour and thirty-five minutes, during which time the mercury had fallen 5¾ degrees. It rained also. Epigast. air 104; circumference of the lungs (pluræ) 103; concave surface of the liver and base of the right lung 104; hypogastrium 103; concave surface of the liver and base of right lung 104, when the experiments ceased.

*Case 19.*—Yellow fever, post-mortem heat. Sept. 13, 1894; air of the room 86 degrees. N. L., a Frenchman, aged 58; sick eleven days; dead five minutes; experiments noted consecutively about once in five minutes; axilla 102; knees brought into contact 102; rectum 104; axilla after free exposure 104; thigh 105, 107, 108; epigastrium 107; thigh 108, 108, 104, 104; left lung 104; right 103.5; thigh 104, 104, 104; right lung (base) 103, left 102; thigh 103; epigastrium 103. September 14, seventeen hours after death, room 86; epigastrium 88.5; thigh 88.5; left chest, 88; calf of the leg 86; middle of the arm 88.5; epigastrium 88.5; thigh in one hour 86.

*Case 20.*—Yellow fever, post-mortem heat. Sept. 18, 1893; S. E., born in Germany; last from Texas; resident, one month; aged 23; sick five days; occasionally delirious; became comatose last night; now dying. Axilla 104 degrees; bend of the arm 102.5; palms 98.5. Died at sixteen minutes before 11 A.M. six minutes after death; axilla 106, eight minutes 107, in two minutes later, 107; one minute 107¼; bend of the arm three minutes later (11 A.M.,) 104, one minute 104; palm two minutes 98.5. A few minutes past noon, resumed the experiments in the deadhouse, the temperature of which was about 88 degrees. The experiments were made successively in the following order, until 1 P.M.: Axilla 107 degrees, and stationary; epigastrium 107, 107.5; right and left hypochondriac 107.5, 107.5; center of upper third of thigh 107.5, 108; axilla 105; brain in the center 105; heart 107; brain 104¾, when owing to urgent circumstances the experiments ceased.

In this case during the agony, and even after respiration ceased, an universal tremor, with strong tension of the muscular system took place, while the fingers and forearms were found flexed, having been for a time very rigid. The treatment consisted of two doses of castor oil; a mixture of magnesia and charcoal in peppermint water, and at the close brandy.

An attentive study of the entire series of cases and observations recorded by Dr. Bennet Dowler establishes the following conclusions:

1. A temperature of 109 degrees, in the axilla in yellow fever is not necessarily fatal. It is probable that in such cases the temperature of the internal organs reaches 113 to 115 degrees.
2. Many cases of yellow fever, in the high temperature, and rapid progress and sudden termination resemble sunstroke (solar asphyxia, *coup de soleil insolatio*, heat stroke). When death takes place in the active stages of both diseases, the post-mortem heat may rise as high as 113 degrees, and remain at this point for varying periods of time.
3. In many cases of yellow fever, the rise of post-mortem temperature can not be referred solely to the arrest of respiration and of cutaneous and pulmonary transpiration and evaporation.
4. Post-mortem heat is not peculiar to yellow fever, but may occur after death from various causes, as lesions of the nervous system, traumatic tetanus, cholera, typhus and typhoid fevers, pneumonia and phthisis. The phenomena therefore can not be wholly referred to the action of the specific poison of yellow fever.
5. In many cases of yellow fever, as well as of other diseases, there is no post-mortem development of heat above that which existed at the moment of death; but on the contrary the bodies obey the ordinary physical laws of the gradual conduction, radiation and loss of heat from the circumference to the center.
6. Post-mortem heat may be due to several causes, among which may be enumerated the following: *a*,

chemic changes in the blood and organs, which continue for a certain period after death; and as the evaporation from the surface of the lungs and skin, as well as the refrigeration of the process of respiration have ceased the full effects of these chemic changes are manifested in the increased development of heat; *b*, the transmutation of the electrical forces and the modifications of physical force known as the muscular and nervous forces into heat.

(To be continued.)

## NERVOUS DISEASE IN EARLY SYPHILIS.

Read before the Chicago Academy of Medicine, October, 1894.

BY G. FRANK LYDSTON, M.D.

Professor of the Surgical Diseases of the Genito-Urinary Organs and Syphilology in Chicago College of Physicians and Surgeons; Surgeon in charge of the Masonic Hospital of Chicago; Fellow of the Chicago Academy of Medicine; Lecturer on Criminal Anthropology in the Kent Law School; Fellow of the American Academy of Social and Political Science, etc.

(Continued from page 248.)

### ANALYSIS OF CASES.

The cases of early nerve syphilis which have been related can hardly be classified arbitrarily, but may with fairness be divided into: 1, cases in which toxin poisoning was the chief factor; 2, cases in which organic cell deposit existed and was the main element; 3, mixed cases in which both factors were probably well marked. That these conditions are often absolutely independent of each other during the active period is hardly credible. I wish in this connection to again direct attention to the fact that the probability of the presence of organic cell deposit is in direct proportion to the duration of the case. Some of the very early nerve phenomena are distinctly toxic; a little later we have a mixture of both, although either may greatly predominate; later still, the toxic factor is of secondary importance. Nerve phenomena associated with a simple typical roseola may be accepted as probably toxic. The existence of eruptions consisting of cell deposit, enhances the probability of cell infiltration of nervous tissue or the vessels supplying it.

Cases 1 and 2 are fair examples of the effects of the syphilitic toxins upon the brain. Not only were the meninges directly intoxicated by the products of syphilitic germ evolution, but there was in all probability a vasomotor neurosis which constituted a still more powerful source of cerebro-meningeal hyperemia. The line between such conditions and actual inflammation is difficult to draw, but judging by the effects of known syphilitic pachy-meningitis later on, it is questionable whether actual inflammation is present in these early types of head disturbance. Its occurrence would not be surprising judging by the effects of other poisons—that of rheumatism for example—upon the meninges and brain. Periosteal involvement may, I think, be laid aside in these cases.

When we consider the excessive engorgement of the pharynx in secondary syphilis, we ought not to be surprised at the occasional occurrence of severe symptoms referable to meningeal engorgement. The faucial hyperemia is, it is true, referred to actual cell deposit—indeed I formerly so regarded it—but I have lately become convinced that vasomotor disturbance has much to do with it.

It would appear that mental disquiet had much to do with the determination of the head symptoms in Case 1. This is an important practical point as

tending to show that syphilis alone may be quite a different matter from syphilis plus anxiety, brain fag or any condition which tends to disturb cerebral circulation and nutrition.

In Case 2 we have in all probability an illustration of what may occur when diathetic conditions and blood impoverishment are superadded to syphilitic infection. It has seemed to me that rheumatism, gout, tobacco and alcohol are somewhat alike in increasing vulnerability of nerve and brain tissue both to syphilitic intoxication and cell growth. Alcohol is especially open to impeachment by virtue of its pernicious effect not only upon the brain cells, but also upon the cerebral circulation. A point regarding the effect of the salicylate of iron which may be pertinent in connection with its results in Case 2, is the fact that I have reason to believe that this preparation is of special value in various toxemias. It has apparently been of great service in the treatment of erysipelas, diphtheria and puerperal septicemia. This may have a direct bearing upon its action in syphilo-toxemia.

Case 3 is by far the most interesting case of my series and is the one which I believe to be most open to controversy. It is possible that the Fellows of the Academy may fear that I am carrying the neuropathic theory of syphilitic phenomena to extremes in classifying this case among them, but there appears to me to be no other logical explanation of its peculiarities. I certainly do not believe that I succeeded in aborting a double pneumonia by the means adopted in this case.

Visceral engorgements and infiltrations are by no means uncommon in syphilis, diffuse infiltration characterizing the early, and distinct gummy deposit the later period. Tenderness over the liver, spleen and kidneys are occasionally observed. Transient albuminuria is not uncommon. I have long entertained the view that more or less transitory circulatory disturbance of the viscera is quite a constant feature of early syphilis. That this is due in any great degree to cell deposit, I do not believe; there is too little disturbance of function as a rule. It would appear logical to infer that certain visceral areas participate in the changes characterizing the roseola, at which time no cell deposit may be manifest in any location. If my position be correct regarding the presence of a sympathetic neurosis produced by syphilitic toxins at this period, the viscera, which bear so important a relation to the sympathetic, could hardly be expected to escape. I have said that there is usually no marked disturbance of function, but I have met with some striking exceptions to this rule. For example, I have seen severe jaundice apparently due to hepatic involvement at a very early period of syphilis.

Hutchinson, I believe, admits that the early lung involvement of syphilis consists of temporary congestions; actual inflammations and infiltrations being reserved for a later stage. Aside from the possible existence of pulmonary vasomotor disturbance as the explanation of the phenomena observed in the case under consideration, it is not beyond the bounds of probability that the syphilitic toxins acted in some peculiar manner in this instance, upon the pneumogastric.

Irritation and hyperemia of posterior nerve roots readily explain the severe intercostal pain.

Case 4 in all probability illustrates the fact that

syphilis is likely to seize upon the slightest point of vantage. The old back strain and a rheumatic diathesis constituted a point of departure for local disturbance. Whether the irritation and hyperemia of posterior nerve roots was in a certain sense a reflex of the muscular disturbance is open to question. I am inclined to the belief that the old injury was the source of local vulnerability, the neuralgic element in the case being, however, the direct effect of the syphilitic toxins upon sensory nerve roots.

The necessity for ordinary measures of local derivation and counter-irritation in this case, are worthy of comment.

Case 5 shows very conclusively that syphilitic brain disease may remain latent for some time, only to develop upon the supervention of some exciting cause. Whether this is true only of the early disturbances of syphilis is open to question. It is a fact, however, that in early cerebral disturbance which is due either to toxins or gradual diminution of vascular caliber, or both, the onset is apt to be insidious, with premonitory symptoms of vertigo, slight aphasia, impairment of memory, cephalalgia, sense of head fullness, melancholy, irritability, or perhaps muscular spasm. The final stroke may be sudden, but some of the foregoing symptoms are likely to have preceded it. The exceptionally sudden development in several of my early cases is a feature of some interest. Later cases, which may be due to thrombosis, embolism, or hemorrhage are, on the other hand, often very sudden. In the case of hemi-anesthesia at present under consideration, the character of the lesion is an open question. Cerebral hemorrhage should be rare in such early cases, the thickening of the vessel walls and perivascular tissue protecting the arteries from rupture rather than otherwise. Collateral vascular strain and hyperemia might possibly explain it. Venous obstruction of limited extent, in the presence of active hyperemia induced by venery and alcohol might have been the essential factor. It will be understood that I do not deny the probability of a small extravasation in this case. I simply wish to assert its rarity in so early a period of syphilis. Its occurrence, however, might show that the localization of vasculo-cerebral syphilis, depended upon some antecedent non-syphilitic disease. This is not likely in so young a subject.

The occurrence of acute ischemia of the affected area is not improbable. The affected area probably accommodated itself to the gradual diminution of the blood supply, incidental to the encroachment of the syphilomatous process. When, however, from any cause the vessels are suddenly occluded the result is well known. The mechanism of this occlusion in early syphilis is not so easily explained. Embolism is not impossible, but is not to be expected in early syphilis. Localized vasomotor disturbance is possible. The toxin element does not enter here, save as a complicating factor; that it is the essential feature of the case is not likely. After a careful survey of the pathologic possibilities in the case under consideration, I am inclined to the ischemic view of the cerebral disturbance. The location of the lesion in the internal capsule or its immediate vicinity may I think be accepted.

The subsequent recovery and prolonged good health of this patient typify the favorable ultimate prognosis of many cases of nervous syphilis. Case 4

quite forcibly illustrates three important features of syphilitic neuro-pathology, viz.:

1. The acutely pernicious action of syphilitic toxins upon the nervous system.

2. The vulnerability of nerve tissue produced by this early intoxication.

3. The importance of such conditions as la grippe and possibly the influence of sexual excess in determining neuropathic phenomena. The early nerve disturbance in this case, I believe to have been due to the following factors: *a*, direct irritation of nerve tissue and spinal meninges, by the syphilitic toxins; *b*, circulatory disturbance—probably hyperemia—of the same tissues and especially of the posterior roots of the spinal nerves, produced by syphilitic intoxication of the sympathetic. The paraplegia which occurred later on, was in all probability due to actual cell infiltration of the motor tracts determined by the perversion of nutrition left by the toxins. For that matter the paraplegia did not occur late enough to exclude toxin action at the time it developed. Even if the toxins were the point of departure, however, cell infiltration was probably the essential factor at this time. I have already spoken of the importance of la grippe in the etiology of this case. The sexual excesses of the patient perhaps had much to do with the spinal determination of the syphilitic poison. The question has occasionally arisen in my mind, whether the causative influence of syphilis in tabes may not be operative chiefly through the secondary factor of sexual excess. Hutchinson reports a case in which acute myelitis was precipitated by sexual indulgence, the patient being well along in late syphilis. I recognize the fact that the true importance of syphilis in the etiology of tabes has not been definitely settled. Alcohol bears a somewhat similar relation to tabetic etiology; it is probably the determining factor that develops morbid changes in the spinal cord in syphilitics, which abstainers would probably escape.

In Case 7 we have an illustration of a condition of syphilitic nerve disease which, while it can hardly be said to be very rare, is yet sufficiently infrequent to be of great interest. In this case the fifth nerve was obviously involved. It would appear that syphilis has something of a monopoly in the production of paralysis of the fifth. Hutchinson states that he has never seen this form of paralysis except from syphilis. I am not in a position either to verify or contradict this assertion. Neurologists of large experience are much more competent to judge. It is to be remembered, however, that Mr. Hutchinson's clinical experience has been enormous. The only cases which I have seen have been due to syphilis, but strange to say, neither of them bore out Mr. Hutchinson's favorable prognostic opinion of such cases. He says: "I do not recollect a single case of syphilitic paralysis of the fifth nerve which was permanent." The apparent contradiction in my cases was probably due to the late period at which proper treatment was begun. In neither of my cases was the cornea involved, the superior division of the nerve probably escaping involvement. Hutchinson has several times removed the eyeball in cases of total involvement of the nerve, the anesthesia from the nerve lesion being so complete that anesthetics were unnecessary. As a rule, only one nerve is involved, cases in which bi-lateral paralysis of the fifth or coincidental involvement of other cranial nerves being exceptional.

Hutchinson believes that the want of symmetry and strict localization of the lesion shows that the trunk or ganglion rather than the origin of the nerve are affected.

The most interesting feature of the case under consideration is the unilateral deafness. So rare is this condition that Hutchinson states he has never seen an example of it. Partial deafness in one or both ears, generally temporary, is by no means unusual in early syphilis. Tinnitus aurium is another aural phenomenon which is not infrequent and is likely to be very stubborn, but may be unaccompanied by the slightest inhibition of audition. In the cases in which absolute deafness occurs the process is not only bi-lateral but may be very fulminant. Unless mercury be vigorously used, incurable deafness is very likely to develop in an incredibly short time. We are almost in the dark regarding the pathology of these cases. Possibly there may be some new pathologic features which the otologists of the Academy can impart to us in the discussion.

Deafness develops during the first year of syphilis, as a rule, is rarely if ever tertiary, and seems to be almost identical in acquired and hereditary syphilis, in which latter condition it is very frequent. The severity and rapidity of the process in connection with the total abolition of hearing which usually results, warrants its classification among the nerve phenomena of syphilis. A disturbance of the relations of the arteries to their bony investments by virtue of a loss of elasticity, thickening and narrowing of the vessel walls, probably explains some of the slighter cases of deafness and tinnitus. Some transitory cases are doubtless due to a syphilo-toxic vasomotor neurosis.

Where cell infiltration in or about the auditory nerve occurs, the pressure and counter pressure on the delicate nerve fiber must be very great because of the unyielding nature of its osseous investments. The syphilitic neoplasm may as usual be quite speedily removed, but pressure and toxic innutrition have done their work and permanent and functionally fatal injury has been produced. I see no other logical explanation of these cases. There is certainly no explanation which could more powerfully emphasize the necessity for early and radical treatment.

A final point of interest is the fact that facial hemiatrophy is exceptionally preceded by neuralgia of the fifth as occurred in my case.

In Case 8 we have an example of cerebral disease in early syphilis which is quite rare, the recorded cases being few in number. The onset of the hemiplegia in this case was apparently very sudden, as the patient afterward told me that he had felt perfectly well before the attack, with the exception of some slight manifestations of syphilitic fever. The lesion in this case was in all probability one of marked vascular infiltration. The presence of papular syphilides showed that the characteristic dissemination of cell deposit had begun. It is probable that moderate ischemia of the affected area preceded the stroke, the final result being due to a sudden diminution or cessation of the already limited blood supply. Theoretical reasoning is our only recourse in such cases and it might be quite as logical to attribute the condition to localized venous obstruction and sudden edema, or possibly hemorrhage, were

it not for the fact that the disease has a greater predilection for the arteries than the veins, and hemorrhage is quite unlikely at so early a period of syphilis. Possibly, however, the effect of alcohol in precipitating the attack of hemiplegia might be best explained upon the theory of hemorrhage, the arteries rather than the veins being the point of departure. Our distinguished Fellow, Dr. H. M. Bannister, relates a very interesting case with features somewhat similar to mine<sup>3</sup>: "I was called into a large store to see a man who had been seized with an apoplectic attack. I found a gentleman between 30 and 40 years of age, completely hemiplegic on the left side. He had not lost consciousness and while mentally somewhat disturbed, was capable of giving a clear account of himself, which was verified by his friends. He had been well, prior to the attack, with the exception of a chancre contracted four months previously. I had him taken in a carriage to his boarding place as he requested, prescribed and promised to call next day. The next morning to my surprise I found him up and dressed; all motor paralysis had disappeared but he was completely aphasic and could only partially express himself by signs. I learned that his hemiplegia had left him during the night, to be followed by his present condition. This also passed off within twenty-four hours, but his mind was left markedly affected, a condition of mild depression and partial hebetude remained which continued until he left the city and passed out of my knowledge."

Dr. Bannister considers this case to have been one of incipient parietic dementia due to toxic cerebral disturbance, and in this opinion I am inclined to agree, but with some qualifications. It is unfortunate that the age of the patient, his previous habits of life, his hereditary and subsequent history were not definitely known. These points would possibly afford additional support to Dr. Bannister's theory of the case, by removing certain features of doubt. As to the cerebral intoxication, it was doubtless a very important factor in the case, but there were certain other elements requiring due consideration. In the first place, cell deposit was to have been expected at the time the hemiplegia developed; vasculo-cerebral changes were probably present with resulting relative ischemia and defective nutrition of the brain. The toxins undoubtedly did their full share in perverting nutrition and inhibiting cerebral function, but the sudden paralysis was probably explicable by their vasomotor rather than by their direct effect. The speedy recovery of the hemiplegia and the apparent alteration of the morbid process from right to left as suggested by the aphasia which replaced the left hemiplegia tend to show this. Temporary vaso-contraction of arteries the lumen of which was already diminished by syphilitic infiltration, would serve as a logical explanation. The resulting mild dementia was probably due to the combined effects of the temporary anemia and the syphilitic toxins.

In Case 9 we have another typical example of early syphilitic hemiplegia with ample evidence of the favorable character of the prognosis under careful and systematic treatment. A very important point in this connection is the fact that such cases should rarely occur. We can not avoid in some cases—possibly in the majority—the early toxin phenomena, for the

reason that treatment may not have time to thoroughly impress the patient before the symptoms of toxin nerve disease develop. When, however, we have several months leeway, we should almost always be able to prevent symptoms due inferentially to arterial disease, providing the patient be intelligent and conscientious.

Case 10 illustrates the fact that recovery does not ensue even in early syphilitic brain disease, unless the syphilitic neoplasm be removed before permanent changes in the affected tissues have occurred. We may sweep away the syphilitic factor in such cases, but we must be very prompt and radical in our therapeutics else nerve ruin be left behind. The pathologic process in the case just related, may have been precocious and verging upon gummy change. It certainly might be expected to be distinct and circumscribed, as suggested by the marked osteo-periosteal changes.

The author has no desire to be arbitrary in his own conclusions regarding any of the series of cases at present under analysis, least of all does he desire to insist on the accuracy of the diagnosis in Case 11. Facial paralysis from other causes is very frequent, while involvement of the seventh nerve in syphilis is very rare; the possibility of coincidence is therefore to be taken into serious consideration. Hutchinson, with his vast experience, recalls only two or three examples of facial paralysis from syphilis and in these cases other cranial nerves were also involved. He quotes Buzzard and Hughlings Jackson as having recorded examples of it. In my own case there was no change for the better until full mercurial treatment was instituted.

Another gentleman—also a physician, by the way—had been under my care for syphilis of a duration of something less than a year. He developed a facial paralysis which our confrère Dr. Church, pronounced syphilitic. As this man has gone through a serious surgical operation and was just convalescent, and moreover, from the fact that he had been over treated if anything, from time to time, I doubt the accuracy of the diagnosis. Recovery was soon complete in this case, and in a recent letter the doctor gives a very cheerful and reassuring account of his condition.

Case 12 is certainly of great interest. It would be difficult to prove the connection of the early tabetic symptoms of undoubted specific origin, with the later manifestations of the typical tabes. The inference of a causal relation of the early symptoms to the later incurable cord disease is, however, apparently fair. At this junction it might be well to again suggest that in many cases of tabes with a syphilitic history, cord intoxication without symptoms may have laid the foundation for later changes.

My friend and colleague, Dr. H. N. Moyer, has observed a case which is also pertinent as bearing upon early spinal cord involvement in syphilis. His account of the case is as follows:

*My Dear Dr. Lydston:*—The circumstances attending the case of which I spoke to you I can only recall from memory, but they are substantially as follows: Some six or seven years ago I was called to see a woman about 30 years of age who was said to be suffering from an obscure nervous trouble. The disease had begun some weeks before I saw her, with quite severe pain in the back and shooting pains in the legs. These symptoms had gradually increased until within a few days of the time when she came under observation, at which time she was compelled to take to her bed. At the time I saw her, she was apparently very sick and suffering excruciating pains particularly in the legs and a

<sup>3</sup> American Journal of Insanity, 1894.

dull heavy aching in the back. She was very restless and sleepless. The pains were described as shooting or darting up and down the limb; the feet were especially painful and there was a feeling as though hot sand were applied to the soles. On examination, there was no special atrophy though there was perhaps some loss of power in the legs. She was able to stand with the eyes open but with them closed she would immediately pitch forward. The knee reflexes were completely abolished. There was impaired tactile and temperature sense in the lower extremities. At this examination I detected a diffuse macular and papular eruption pretty generally distributed over the entire body and which up to that time had not attracted the attention of the attending physician. The eruption also was present upon the palms of the hands. Suspecting the specific nature of the eruption I immediately questioned the husband who admitted that about ten months before he had been infected, but after six months treatment his physician had advised him to marry and he had done so.

"To my mind, there was no question that the specific infection was directly responsible for the acute ataxia in which I found the patient. An examination of the genital organs did not reveal any primary sore. I saw the patient on one or two occasions after this visit and learned subsequently from her physician that under free use of the iodids with mercurial inunction, the pains rapidly disappeared and the patient made a quick recovery. Within three or four weeks she was going about attending to her ordinary household duties. It would be interesting if at this time I could see and examine the patient, but unfortunately I do not know where she is. It is the earliest case that has ever come under my observation."

I greatly regret the lack of accurate data in Dr. Moyer's exceedingly interesting case. The absence of subsequent history is especially to be regretted. Such incompleteness of detail is so frequently unavoidable that many of our most valuable clinical experiences are sadly marred. Despite the lack of certain details, however, there is no doubt as to the accuracy of the diagnosis of Dr. Moyer's case.

It has not been my fortune to observe cases of early brain syphilis with mental symptoms as the predominant element. A number of such cases are on record. Most of these cases have been collected by an eminent Fellow of this Academy, Dr. J. G. Kiernan's paper being a brief yet comprehensive survey of the literature of the subject of early syphilitic psychoses. I take the liberty of quoting his references and cases in full.<sup>4</sup>

(To be continued.)

## NEW INSTRUMENTS.

### AN IMPROVED INSTRUMENT FOR DRAINING THE ABDOMINAL CAVITY AFTER LAVAGE IN ABDOMINAL SECTION.

BY J. H. KELLOGG, M.D.  
BATTLE CREEK, MICH.

Every ovariectomist who has had any considerable degree of experience has some time felt the need of an efficient means by which the abdominal cavity could be conveniently and completely drained of fluid after washing out, so as to avoid the necessity of inserting a drainage tube for this purpose in completing an operation. "Always drain when you wash out," has long been an accepted maxim with many ovariectomists, and the fact that those conditions which require washing out are very generally such as render the drainage tube an absolute necessity, or at any rate a wise precaution against the extension of septic processes or a comforting assurance in relation to

internal hemorrhage, will enable the drainage tube to hold its place in abdominal surgery, notwithstanding the cry raised against it by those who happen to have the good fortune to score a long succession of recoveries without its use. Now and then, however, a case is encountered in which one hesitates to incur the risks of the drainage tube, balancing on the one hand the danger which may be incurred if the drainage tube is omitted and, on the other hand, the possible danger of hernia from difficulty to secure immediate union when a drainage tube has been *in situ* for twenty-four or forty-eight hours; of wound infection through the difficulty of maintaining absolute asepsis in the care of the drainage tube; of possible intestinal fistula from pressure of the inner end of the tube against some portion of the intestinal canal, the nutritive supply of which has been weakened by the breaking up of long existing adhesions. The fact that in cases in which washing out is required, more or less unusual risk is necessarily involved by reason of the grave character of the case, renders important the employment of every possible means of lessening the risk of any unfortunate complications which can possibly arise subsequent to the operation. There are, certainly, several classes of cases in which if the surgeon could feel absolutely sure that every drop of fluid had been removed from the abdominal cavity, he would feel much happier to leave the case with the abdomen completely closed than with the most approved form of aseptic drainage tube in position. There are three classes of these cases:

1. Those in which the abdominal cavity has been washed out in consequence of a sudden rupture during the operation, of a thin-walled cyst, allowing the escape of colloid matter, which in itself is not toxic but is capable of furnishing a favorable nidus for the development of air germs, more or less of which must always find entrance to the abdominal cavity during the operation in spite of the most careful aseptic precautions, and which are sure to develop and form their characteristic toxins if fluid remains behind in the abdominal cavity. It is true that often in such cases nature ultimately triumphs by absorbing the fluid, ptomaines and all, thus starving out the mischievous microbes, but the lowered vital resistance of the patient who has undergone a complicated and prolonged surgical operation sometimes prevents this happy conclusion of the matter.

2. Cases of ascites due to fibroids of the uterus, papillomata of the uterus or appendages, or peritoneum, tuberculosis of the peritoneum or fibroid of the ovary. This ascitic fluid, while innocuous so far as toxemia is concerned, before the opening of the abdominal cavity, after air germs have been admitted, so encourages the growth of microbes that local or general peritonitis may easily result, so that washing out is frequently justifiable, especially where there has been any escape of blood into the peritoneal cavity, resulting in general soiling of the intestines.

3. In cases in which through the rupture of a pus sac, or some similar source of infection, deep portions of the peritoneal cavity have been soiled, notwithstanding the walling off of the intestines and greater portion of the intestinal cavity by sponges or napkins. Every operator knows how readily such soiling may occur through the rupture of a firmly adherent pus tube, or a suppurating ovary, notwithstanding the most careful and dextrous manipulation in freeing the diseased parts from the surrounding tissues.

<sup>4</sup> Medical Standard.

There are, perhaps, still other cases in which if the operator could feel that the peritoneal cavity had been thoroughly cleansed and was entirely free from fluid, he would leave his operating room or surgical ward in a much more contented state of mind than after introducing a drainage tube, with the knowledge which the experienced surgeon appreciates much better than the tyro, that eternal vigilance in watching the drainage tube is the price of even a moderate safety from the dangers which its use involves.

After this perhaps somewhat lengthy introduction, I desire to present a new device, by which, in cer-

tain cases at least, it is believed that the necessity for the use of the drainage tube may be obviated. The device illustrated in the accompanying engraving consists of a metal tube about one centimeter in diameter, the lower end of which is inclosed in a cage, which not only guards the tube laterally, but by extending a little beyond the lower end of the tube also protects its lower extremity. The advantage of this construction will be readily appreciated. The diameter of the cage is about one inch. It thus creates a sort of well about the tube, in which the fluid may collect. The circumference of the well is seven centimeters, as compared with three and one-half centimeters for the tube. The length of the tube is eight centimeters. We thus have a drainage area of fifty-six centimeters, whereas in the use of an ordinary wash-out tube there is often no drainage area at all created in consequence of the intestine, omentum, or other loose tissue being drawn up against the end of the tube by the suction of the siphon or the evacuating syringe. At best, the whole drainage surface of the tube without the cage can scarcely be reckoned as more than three-fourths of a square centimeter. The protection of the lower end of the tube by the cage prevents obstruction, so that the fluid accumulates about the end of the tube, from the surrounding tissues. By introducing the instrument to the various parts of the abdominal cavity, and especially to the most dependent places, the whole peritoneal cavity may be quickly and perfectly drained.

I have tested this instrument in a number of cases and find it admirably suited for the purpose for which it was designed. In a recent case it proved very useful, indeed, serving a new purpose by which it became more useful than I had anticipated. The case was one in which I had removed a very large malignant kidney by the lumbar method. I found it necessary to extend the opening anteriorly to enable me to get the mass out. The tissues were so friable that just at the last moment, notwithstanding careful manipulation, a portion of the malignant growth gave way under pressure of the fingers, and a sudden gush of blood occurred which left present a great number of clots packed away in each of the little pockets which had been formed by the numerous nodules of the tumor. The weakness of the patient rendered necessary the completion of the case at the earliest possible moment. Recalling my caged

tube, I thrust it into the cavity at once, and while the stream of water was flowing, carried it around to every part of the wound, and was surprised at the facility with which I was able to do this which was due, I am sure, to the large surface presented by the cage, which prevents its entanglement with surrounding tissue. I was also able to pass it freely everywhere without fear that the end would be thrust through the thin septum which intervened between the cavity from which the kidney was removed and the peritoneal and pleural cavities. After the wound had been sufficiently washed, I simply separated the tube from the fountain and dropped the end into a vessel upon the floor when the powerful suction of the siphon thus produced quickly emptied the whole cavity, drawing out through the tube such small clots as had not been previously lifted out by the force of the inflowing stream, and when I removed the tube I was pleased to find that the enormous cavity, which was nearly large enough to receive a man's head, had been completely obliterated, its walls being drawn up around the cage, in following the water as it receded. Examination showed that the cavity was entirely free from clots, and it was only necessary to tuck in a strip of iodoform gauze, close the wound, and rapidly introduce a few sutures to complete the operation.

In conclusion, it is but just that I should state that the idea of this instrument was suggested to me by Dr. Eastman's well, which accomplishes much the same thing, although somewhat less convenient in use. I must also thank Wm. H. Armstrong & Co., of Indianapolis, for the pains they have taken to construct the instrument according to the plans I have given them.

#### A NEW CLUB FOOT WRENCH.

BY STEWART LEROY McCURDY, A.M., M.D.

Professor Orthopedic Surgery, Ohio Medical University; Orthopedic Surgeon Protestant Hospital, Columbus, Ohio; Member American Orthopedic Association; Lecture Topographical Anatomy, Western Pennsylvania Medical College, Pittsburg, Pa.

PITTSBURG, PA.

In the treatment of the various forms of talipes even after tenotomy of the tendo-Achilles, or the plantar fascia of other muscles and ligaments, or as individual case may require, great force is required to break up the adhesion between the tarsal bones.

The bones which have been in abnormal position for years are bound together by dense adhesions, and have new articulating facets in abnormal position.

These distorted relationships must be disturbed. The hand of the average surgeon is not sufficiently powerful to bring the foot to a normal position. It may be necessary to even fracture the bones to overcome the deformity and when it is found necessary to do so it should be done, for by the time treatment is completed the fracture will have had ample time to unite.

The "T. T." or "Thomas Twister" as introduced in this country by Dr. Ridlon is not entirely satisfactory as a club foot wrench. Phelps machine is all powerful but it is quite complicated, expensive and cum-

bersome. Neither of the machines can be kept absolutely clean. The wrench herewith illustrated is simple, can be kept aseptic and is not expensive. While the handle is to one side of the foot in the "T. T.," the handle is in the center of this instrument, and there is great advantage given the operator in power without the annoyance of the wrench slipping around the foot. The set screw shown allows an adjustment to any sized foot. The bars as they come in

contact with the skin are protected with rubber tubing, thus avoiding the liability of contusing the skin. The wrench should be used after tenotomies have been done, for the forcible correction of the foot, in cases of talipes-equino varus, or equinus, and always done under an anesthetic. It may be used in any variety of deformity of the foot, hand or other joints of the extremities.

## SOCIETY PROCEEDINGS.

### Louisville Academy of Medicine.

The Academy met in their rooms, Monday evening, February 4, DR. T. L. McDERMOTT, President, in the chair.

DR. W. B. PUSEY exhibited an intubation tube "introducer," a modification of O'Dwyer's. It is a much lighter instrument, doing away with the spiral spring with which the tube is pushed off in the original introducer, thus making it much easier to clean. It also has a notch in which the thread rests. He also exhibited an extractor which he stated was in the experimental stage and had not been put to practical use yet.

DR. DUGAN showed a specimen removed from a child 6 years old, consisting of the trochanter and two inches of the shaft of the femur below. The child had applied to a surgeon for hip joint disease, and a splint was applied with extension. Under this treatment the patient gained in flesh until about six months ago, when she began to fail. She was put on tonics and again improved for a time. When seen by Dr. Dugan there was a boggy mass outside the thigh, which had discharged in the region of Ponpart's ligament on right side. The thigh moved on a small axis, and a spontaneous fracture was suspected, especially as there was a history of a fall one year ago. The detached trochanter was removed and two inches of the shaft which was in the condition of osteomyelitis. The periosteum was detached but healthy.

DR. CHEATHAM showed a calculus which he had removed from Wharton's duct. Two years ago a calculus had discharged through an abscess. This one was removed without difficulty after an incision, the forceps being introduced and the calculus grasped. It was situated under the tongue and about one-fourth inch from the opening, and could be distinctly felt with the finger.

The discussion upon diphtheria was then begun.

DR. KOEHLER read a paper upon the

### BACTERIOLOGIC DIAGNOSIS.

He stated that the bacteriology of diphtheria was based upon the supposition that all cases in which the Löffler bacillus is found are true diphtheria, and if not found it is a pseudo-diphtheria, which is not contagious or infectious. The bacteriologic examination is a valuable hygienic measure. The malignancy of the diphtheria bacillus is not based on theoretical grounds. The description of the bacillus and its method of culture were then briefly explained. The position of the bacteriologists is misunderstood. They do not hold that typical cases of diphtheria need a bacteriologist to make the diagnosis. Any competent physician can do that, but there are cases obscure in their nature which may be the source of disseminating the disease among many, in which a bacteriologic examination makes the course to be pursued perfectly clear. In the series of cases examined by Drs. Frank and Koehler, the staphylococcus was most frequently associated with the bacillus of diphtheria. Of the fifty cases, sixteen were diagnosed as true diphtheria, three of which did not have the clinical symptoms of diphtheria. Five of these were fatal. In the cases of pseudo-diphtheria there were no serious symptoms.

DR. KOEHLER took the stand that all cases in which the bacillus is not found are non-infectious; but when found, if the clinical symptoms do not point to diphtheria, they must be treated as such, especially in regard to isolation, etc.

DR. W. E. GRANT read a paper upon his

### EXPERIENCES WITH THE ANTITOXIN SERUM OF BEHRING.

He thought that it was a mistake for a comparison to be made between the diphtheria antitoxin and Koch's tuberculin, as the action of the two and their composition were so different. The diphtheria antitoxin has only a local influence, neutralizing the product of the disease germ, and for this reason he also used in conjunction with the antitoxin, local treatment as well as constitutional treatment as the latter was indicated; the antitoxin had been very prompt in its action. Löffler's bacillus had been found in each case. There had been no skin complications, no joint pains, no kidney troubles. The injections were made in the back under the strictest antiseptic precautions. The large needle was used, as the viscid character of the serum necessitated the large caliber. Pain was no factor, but the twisting of the child may break the syringe or the needle, and a practical suggestion was made to have an assistant hold patient over his shoulder, holding his neck and legs, thus arching the back and holding him firm. The local treatment consisted in the application of fifteen volume peroxid of hydrogen, 3iv, and bichlorid of mercury 1 grain. Constitutionally, whisky was given freely 3ij daily, with tr. chlorid of iron and chlorate of potassium, the latter given until the second day only. Digitalis and strychnia as indicated. He reported five cases in which the antitoxin had been used with recoveries in all, though one case was *in extremis* when the remedy was administered.

DR. J. M. RAY read a paper upon the

### LOCAL TREATMENT OF DIPHTHERIA.

As the disease is primarily a local one and the poison is generated here, the treatment must be begun early and that point attacked. The indications are: 1, destroy the germs; 2, neutralize the toxic products; 3, limitation of extension of the membrane. The prophylaxis is an important element. Adenoids and enlarged tonsils should be removed in those exposed especially; all discharges in those with diphtheria must be destroyed and the clothing, etc., boiled or otherwise disinfected. Local treatment necessarily has its limitations; a spoiled child by its struggling might be injured, or one much prostrated, made worse from loss of valuable vital force from poorly applied efforts at local treatment. The application of powders, if bitter, destroys appetite by creating a bad taste in the mouth. The situation and extent of the membrane and stage of the disease is a guide to the administration of local treatment. If diphtheria of tonsils, pharynx or nose, a warm alkaline cleansing solution is best, a combination of sod. bicarb., sod. chlorid and boric acid, this used as a douche, and when warm is a painless application. As a spray the best is the following:

R. Hydrarg bichlorid . . . . .	gr i.	106
Glycerin . . . . .		
Peroxid hydrogen (Oakland) aa . . . . .	3ij.	64

which if very irritating will be made neutral by adding salt or soda in small quantities. Iron has a good effect, as it destroys and shrinks the membrane. Powerful antiseptics are contra-indicated. In the laryngeal cases the laryngologist rarely sees a case until intubation is indicated. If seen early,

sprays are of no avail; we must use vapors or steam. Tr. benz. co. is pleasant and effective with ac. carbolio and eucalyptol. The Brooklyn or Corbin treatment is very effectual in laryngeal diphtheria. Statistics were given of 358 intubations without this treatment with 28 per cent. recovery, and 218 intubations in which the calomel sublimation treatment was used with 39.8 per cent. recovery. A lamp used in this treatment was shown which is used by Dr. Dillon Brown.

Dr. D. G. DABNEY spoke on the

VALUE OF THE LOCAL APPEARANCES IN DIPHTHERIA AND THE PROGNOSIS.

Only the nasal and pharyngeal varieties were spoken of. The progress in this disease was due to the advanced knowledge of the pathology, treatment and the less severe epidemics. In every suspicious case a bacteriologic examination should be made, especially if the case is a mild one. But even where the diagnosis of diphtheria is made bacteriologically it is oftentimes difficult to convince one's self that it is diphtheria because of the mildness of the form. The more extensive the membrane, the more toxin is produced, and the more grave the prognosis. If little membrane there is generally not much trouble. Cases of follicular tonsillitis are less ominous at the beginning but prognosis should always be guarded. The nasal form is always more serious because of the number of absorbents and the likelihood of a laryngeal diphtheria supervening as a complication. Nasal bleeding is a bad omen, also the extension of the membrane deeply and rapidly. Early enlargement of the glands of the neck and the presence of adenoids influence the prognosis.

Dr. W. B. PUSEY read a short paper on

INTUBATION IN DIPHTHERIA.

He gave the history of this treatment of diphtheria, and paid a tribute to O'Dwyer. The advantages over tracheotomy are obvious, especially to any one who has seen an intubation. In some cases a secondary tracheotomy is necessary but they are not many. The tube is generally worn from five to ten days, the average time being seven days as a rule. In one case he had had, the tube was worn twenty-four days, being removed every five or six days, with recovery; another had coughed up the tube at the end of twenty-four hours and re-introduction was not necessary. This is not always easy to do, but in most cases it can be performed without difficulty. Under eighteen months, the parts are so small and the tube is often longer than the length from the epiglottis to the vault of the pharynx. This makes introduction and especially extraction of the tube almost impossible. Of the 147 cases in which he had intubated, 66 recovered, 44.9 per cent. The ages ranged from 8 months to 9½ years. The introducer exhibited earlier in the evening he had used three years and it was very satisfactory.

Dr. T. C. EVANS read a paper on the

CAUSE OF DEATH FOLLOWING DIPHTHERIA.

The value of intubation is not underestimated, but so many cases occur in which intubation offers so little help; the operation is easily and quickly performed as a rule, and there is no blood, but the results are far from satisfactory. The most frequent cause of death is broncho-pneumonia, due to or existing with the extension of the membrane downward; a nephritis, heart complications, sepsis or accidental causes, among which may be mentioned strangulation from pushing down the membrane, prolonged efforts at introduction of the tube, and from the exhaustion supervening from the removal. Northrup's statistics of 103 autopsies from diphtheria were quoted; in 72 cases there was extension of membrane downward. The broncho-pneumonia of diphtheria differs from the ordinary form, or that following the exanthemata; it generally runs a rapid and fatal course by the end of the second day, not often as late as the fourth day. The picture of a case relieved by intubation is a marked one, the quiet peaceful sleep, lessened respiratory embarrassment. In twenty-four hours afterward there is a loss of appetite, the child is restless, there is an elevation of temperature and an increased pulse and respiratory rate; an examination of the chest generally shows râles over the base; there is little or no cough but a temperature from 103 to 105 degrees, shallow respiration, dilatation of alae nasi, with a rapid and feeble pulse. There is an inspiration of mucus and saliva from the trachea, which is highly suggestive of the death rattle. The pathologic condition present is an extension of the membrane all the way down; it may be discrete or confluent all through, differing lower down in the bronchi from that in the larynx; in the former place being easily

detached. It generally consists of a cast of the larger bronchi and in the smaller tubes the membrane with the exudate may plug up the bronchioles and beyond there will be collapsed vesicles or emphysematous lung. There also exists a peri-bronchial inflammation. The question of importance is, Does intubation bear a causative relation to broncho-pneumonia? All the conditions are present for an aspiration pneumonia, and as a rule the patients do not live after the second day.

DISCUSSION.

Dr. W. CHEATHAM objected to the use of the term pseudo-diphtheria, because it is misleading. The bacteriologic aspect of diphtheria is much underestimated. Two cases were given in point to illustrate how an error which may prove fatal can be made in clinical diagnosis alone. Dr. Ray's paper in the light of the antitoxin is superfluous. The alkalies do no good, as we know the bacillus grows better upon an acid medium. If antitoxin is used no local treatment is needed, unless a simple salt solution be used as a wash. He had had five cases in which he had used the antitoxin personally and four cases in which it had been used under his observation and all recovered. But this is not unusual here, especially if there is no larynx involvement. All the bad results noted are swelled and painful joints and erythema; the important point in connection with the use of the antitoxin is its early use.

Dr. R. C. GILBERT.—The tube is certainly a great stride forward, but we need some treatment for those intubated cases which die. Much diphtheria goes unrecognized until diagnosed by the sequelæ; hence the importance of an examination bacteriologically.

Dr. WEIDNER wished to know of Dr. Cheatham why local treatment should not be used in conjunction with antitoxin. We all know that the disease is primarily a local one, that the toxic product is neutralized by the antitoxin, but the production of the toxin must be stopped by local treatment, by removal of the membrane. He is a believer in the antitoxin, but the results are not as encouraging as he would wish. The difference of epidemics, the difference in the sequelæ make the taking of statistics difficult.

Dr. H. E. TULEY reported a case of laryngeal diphtheria, primary, in which he had used the antitoxin. Child 3½ years old; seen five hours after first symptoms; there was a temperature of 103½ degrees; pulse 160; great obstruction to inspiration with recession of suprasternal and clavicular notches, and of the intercostal spaces; great prostration and cyanosis. Intubation was suggested but deferred until antitoxin could be produced; 250 units were administered two hours later, with improvement in a short while of all the symptoms. A second dose of 500 units was given on next morning, and child made a rapid recovery. The first injection was only partially given, as one-half of the 500 units were lost by struggles of child, this illustrating the point made by Dr. Grant in his paper.

Dr. LOUIS FRANK emphasized the importance of the bacteriologic diagnosis. A great many cases are perambulatory and disseminate the disease. A diphtheria may be grafted on a follicular tonsillitis and examination should be made during the progress of the case.

In the series of cases reported by Dr. KOEHLER, in every case the pus producing organism (the streptococcus) was found. These cause more trouble oftentimes than the bacillus; they cause sepsis and great depression—and this fact alone should induce us to use local treatment. The antitoxin only neutralizes the toxin. The bacteriologic examination should be made as a diagnostic agent, during the course of the disease and during the convalescence, and complete disinfection should follow every case. He stated that diphtheritic laryngitis and membranous croup are identical.

Chicago Ophthalmological and Otological Society.

Regular meeting, postponed one week, held at the Saratoga Hotel, Jan. 15-18, 1895. Dr. Hotz in chair. There were twenty-four members in attendance.

The Treasurer's report showed a balance of \$60, Jan. 1 1895. This was ordered audited by a committee consisting of Drs. Westcott and Starkey.

The following officers were elected for the ensuing year: President, Dr. F. C. Hotz; Vice-President, Dr. H. Gradle; Secretary, Dr. C. P. Pinckard. Committee on Membership, Drs. W. H. Wilder, E. L. Holmes, G. F. Fiske.

Dr. W. E. Gamble was elected a member.

On motion, the Secretary was instructed to provide a ballot box.

On DR. GRADLE's motion, it was voted that the Society set apart certain evenings for discussion of stated topics, such topics to be announced at the preceding meeting.

DR. TILLEY reported three cases of asthenopia, relieved by crossed cylinders of equal strength. Efforts had been made in each case to relieve the condition by spherical lenses, by cylinders and by combinations of both. In every case there was a considerable amount of astigmatism as seen by the ophthalmometer, but in no case could the patient's vision be improved by astigmatic correction. First case seen in September, 1894. Repeated trials were made with spherocylinders to relieve the asthenopia but without success. On trying a  $-2.00$  D. axis  $180^\circ \subset -2.00$  D. axis  $90^\circ$ , the patient read 6-6 easily. After repeating the test several times, glasses were ordered and patient has been comfortable since. Second case was a lady about 45; had never seen with comfort, wearing  $+5$  D. With  $+2.50$  axis  $90^\circ \subset +2.50$  axis  $180^\circ$  vision rose from 6-18 to 6-6. These were worn a week with comfort, and then  $+4.50$  axis  $90^\circ \subset +4.50$  axis  $180^\circ$  was ordered for near. She has been using them with comfort ever since. Third case, vision was raised from 6-12 to 6-5 by  $-.50$  axis  $90^\circ \subset -.50$  axis  $180^\circ$ , and asthenopia relieved. Samples of crossed cylinders, ground by F. A. Hardy & Co., were shown.

DR. HOLMES had had a similar experience with a cataract case.

DR. STARKEY had tried such combinations but not with much success. He had seen cylinders with axes not at right angles give relief.

DR. GRADLE referred to articles by Manthner and by Channing where cylinders crossed had given relief.

DR. HOTZ referred to the fact that in mixed astigmatism crossed cylinders were better than spherocylinders. The field is said to be flatter and there is less spherical aberration.

DR. TILLEY had seen a patient wearing  $+9$ . axis  $90^\circ$  combined with  $-8$ . axis  $180^\circ$ .

DR. WILLIAMS showed Snellen's modification of Donder's instrument for measuring the color sense quantitatively. The essential feature is that the illumination as well as the size of aperture can be accurately varied. The trouble is that a different normal standard should be made for each color.

DR. HOTZ then spoke about the theory of the symmetric action of the oblique muscles in oblique astigmatism, so persistently advocated by Dr. Savage. He showed that Dr. Savage has given us no proof of the existence of such action of the muscles. Dr. Hotz has never been able to find such action in any case of oblique astigmatism and denied that the supposed rotation of the eyeballs caused by this action would benefit binocular vision. He further proved by demonstrations that oblique astigmatism does not cause obliquity of the retinal images and showed that the laws of physiologic optics do not sustain such doctrine. The theory is based on false premises and wholly untenable.

C. P. PINCKARD, Secretary.

### American Electro-Therapeutic Association.

*Fourth Annual Meeting held in New York Academy of Medicine, New York, Sept. 25, 26, and 27, 1894.*

WILLIAM J. HERDMAN, M.D., President.

FIRST DAY, SEPTEMBER 25, MORNING SESSION.

The meeting was called to order at 9:30 A.M., by the PRESIDENT, DR. WILLIAM J. HERDMAN, of Ann Arbor, Mich., who said: By virtue of the authority with which I am endowed, and by means of this emblem which I use for a gavel, I declare to you that the fourth annual meeting of the American Electro-Therapeutic Association is now convened. We will hold a brief executive session in order to facilitate our future work. The first order of business is the consideration of an amendment to Article III, of the Constitution, notice of which has been given for one year as required by the Constitution.

"Every candidate for admission to the Association shall be required to present a paper to the Executive Council at least one month before the annual meeting." This is a re-

quirement which is not unusual, and we think it is time we should at least consider the advisability of adopting such an amendment.

DR. A. H. GOELET, of New York City—As the proposer of this amendment I will say that I suggested it because I believe it is the only way we can be sure of getting good men into the Association. I hope very much that it will be passed. It certainly will not exclude any desirable person from the Association.

DR. HOLFORD WALKER, of Toronto—If this amendment takes effect does it apply to the members now to be voted upon?

THE PRESIDENT—No; only for future candidates for membership.

DR. R. J. NUNN, of Savannah—In view of the light attendance, I would move if it be in order, that the discussion be deferred until there are more persons present.

THE PRESIDENT—This matter has been brought so thoroughly before the members that I think if they were especially interested in the subject they would take pains to be present. [Motion not pressed by Dr. Nunn.] A vote was then taken, and the amendment was carried, Dr. Robert Newman, of New York City, alone voting in the negative.

The Secretary then read the list of those proposed by the Council for membership.

Ordinary Fellows: L. A. W. Alleman, M.D., 64 Montague Street, Brooklyn, N. Y.; W. H. White, M.D., 192 Dartmouth Street, Boston, Mass.; C. O. Fairbank, M.D., 25 West 45th Street, New York City; Robert M. Slaughter, M.D., Theological Seminary, Va.; J. Griffith Davis, M.D., 200 West 14th Street, New York City; Robert Safford Newton, M.D., 103 East 16th Street, New York City; Caleb Brown, M.D., Sac City, Iowa; Henry S. Jewett, M.D., Dayton, Ohio; David Inglis, M.D., Detroit, Mich.; William M. Hutchinson, M.D., 205 Clinton Street, Brooklyn, N. Y.; Francis B. Bishop, M.D., 1913 I Street, Washington, D. C.; O. B. Douglass, M.D., 123 East 36th Street, New York City.

Associate Fellows: Charles F. Scott, M. A. I., M. A. T. T., Pittsburg, Pa.; R. G. Brown, E. E., 158 Montague Street, Brooklyn, N. Y.

Honorary Fellows: M le Docteur J. Bergonie, 6 bis rue du Temple, Bordeaux, France; Professor D'Arsonval, Paris, France; Professor John W. Langley, Case School of Science, Cleveland, Ohio; Professor Elihu Thomson, M. A. I., E. E., Lynn, Mass.

On motion of DR. CHARLES R. DICKSON, of Toronto, the Secretary was instructed to cast a ballot for the list of all names as read. Seconded and carried.

### SCIENTIFIC SESSION.

DR. WILLIAM J. HERDMAN, of Ann Arbor, Mich., delivered the President's address.

### THE FUNCTION OF THE AMERICAN ELECTROTHERAPEUTIC ASSOCIATION.

A remarkable activity and interest seems to have been awakened in all that relates to electro-therapeutics since the organization of this Association a few short years ago. It would be presumptuous for us to claim that this is, in any considerable degree, the direct result of our efforts. On the contrary, we may more rightly conclude that this Association is but the natural crystallization from a medium that was already saturated with thoughts, facts and efforts, having a relationship to electro-therapeutics, but "without form and void" until its advent. The more familiar we become with the history of the achievements of mankind, the more apparent it is that the plan of evolution is as applicable to the world of mind as to that of matter. No advance is made that has not been long in preparation, and while it may appear to the thoughtless observer, that chance and accident determine results, to him who looks with deeper insight, the myriad workers are disclosed beneath the surface, to whose efforts we are indebted for the progress of to-day. The formation of this Association four years ago was no accident.

It came into being as the natural and necessary result of the requirements of the times. Prophets had heralded its birth and wise men had long hoped and looked forward to its coming, and were prepared to bring the fruits of many years of their choicest thought and earnest labors to lay at its feet. For centuries, knowledge has been accumulating in independent channels concerning the part which electricity plays in the universe of matter and of force.

The chemist and the physicist have discovered, little by little, how important a factor it is in producing the phenomena which occupy their attention; while those who busy themselves with the phenomena of life, the biologist, the botanist and the physiologist are continually forced to recognize how indispensable is the presence of electricity in the building up and breaking down of vegetable and animal tissues, and in the conduct of all vital processes. The physician also—who in his best estate must be a combination of all these specialists, and more—long before any of them, observed that electric force was in many ways intimately related to animal organization, and could be made to influence and modify its functions at will. Notable among the leaders of thought, to whom history points, when tracing out the beginnings of the science of electricity, are such physicians as Gilbert, Galvani and Duchenne, whose remarkable labors in the field of physics and biology, may be said to have awakened the world to the importance of electric energy as a factor in determining the phenomena peculiar to each of these branches of modern science. But starting from these early suggestions, the physicist and the physiologist, the biologist and the physician has each pursued his independent way while seeking to discover the part that electricity had to do, or might be made to do, within his special field of observation. For a long time they seemed to have little in common, and but little intercourse between them was sought for or thought desirable. Each has evolved his own apparatus; established his own methods of research; created his own nomenclature and terminology, promulgated his theories of electric action and accumulated his facts.

Artificial barriers have thus sprung up between these lines of research, due to provincialisms in language and thought which are the necessary consequence of specialization. But each has found that he has been dealing with a force or energy whose activities extend far beyond the limits of his narrow field, and eagerness to know more of its nature and capacities has tempted one and another to overstep the boundaries of his own domain to learn what his neighbor has discovered, and get some hint that may expand his vision, and lead to larger concepts of the truth.

Man is a little cosmos and he who assumes to deal with human ailments, and attempts to set them right, must needs provide himself with every resource that will fit him for his task. The physician, then, who honestly sought in electricity an agent for the correction of some of the disordered states and functions of the body, could not, in the face of accumulated knowledge, longer hold aloof from his fellow-worker engaged in like attempt, or from any who could bring testimony of value concerning the nature of the agent he employed. In his desire to know all that was known, or could be known about this potent force, the electro-therapist recognized it was time to bring these goods to a common storehouse.

Thus was the American Electro-Therapeutic Association conceived by the wise men who first organized it, and placed it on the solid and comprehensive foundation where we find it to-day.

And now may I be permitted to briefly enumerate certain of its important functions by way of confirming the declaration I have made, that it came in the natural course of evolution, a necessary result of the progress of the times. Primarily it has a duty to perform in the improvement of electrical nomenclature and terminology. Electricity has been found to have a universal relationship to the phenomena of matter, both organic and inorganic. Those who study its manifestations, if they would interchange thought, and widen their conceptions of its action through conference, must understand each other when they meet and adopt a common language. We must have a cosmopolitan language in electric science. Words must mean the same to the electro-therapist that they do to the physicist. For the sake of simplicity, clearness of thought, and in the interests of progress, the electro-therapist must be willing to lay aside his "galvanism" and "faradism" and speak of "direct" and "induced" currents, while the physicist, the electrical engineer and the biologist, on the other hand, must avoid the extremes of peculiarly technical expression while discussing questions in a congress of this character that

have a wider scope than the limits of any one specialty. This Association, wisely providing as it does for representation from other departments of electric research, affords a channel wherein the gradual erosion of these relics of former separation will naturally disappear in the efforts toward mutual understanding, and greater simplicity and uniformity in expression will result, with wider comprehension of the truth.

We are thus led naturally, to refer to a second important function of this Association; the opportunity that it affords for the worker in pure science and the technologist to meet and compare results. The fruits of the labor of the one, enlighten and stimulate the other. The fact that the originators of this Association were prompt to recognize the value of this feature, is convincing proof that they were fitted for their mission and were "chosen vessels." Our membership is already strong in the department of electrophysics, the groundwork of the science we are attempting to build up. But in that intermediate stage between the play of forces in the inorganic world, and their part in the disordered vital processes we have much to learn before we can rationally and most efficiently adapt therapeutic methods to disease. We are in much need of the investigations of biologists and physiologists, who following in the steps of Du Bois-Reymond and D'Arsonval will determine for us the "characteristic of excitation" within normal limits for each and every form of electric energy that can be applied in therapeutics. The addition of a few more experimental biologists and physiologists to our membership would result in mutual helpfulness and materially aid in fulfilling the purposes of this Association. Again, an association of this character was needed to assist in fixing a uniform standard of electrical measurements. The Congress of Electricians in council in Paris in 1881 passed a resolution asking that an uniform system of measurement of electric stimuli be introduced into physiology and therapeutics. The advantages to be gained by such uniformity are self-evident, and it is an indispensable requisite to further progress. At the time the Electric Congress made this suggestion there was no organization in existence, national or international, competent to represent the physiologists and electro-therapists, and take the initiative in this matter. Through the character of its membership, this Association is peculiarly fitted for this duty and it should not be lost sight of in our deliberations and discussions.

Again, the times are ripe for the introduction of instruction in electro-therapeutics into the regular curriculum of all our medical colleges. The medical educator can no longer afford to disregard the therapeutic value of a force that has been shown to influence animal organism and modify life processes in so many ways. This Association has already done much to redeem the practice of electro-therapeutics from neglect and shown the folly of the contempt with which it has been regarded by many members of the medical profession. The incontrovertible testimony and demonstrations that we have been able to furnish of its efficiency have already restored many a scoffer to his right mind, and transformed him into a penitent disciple. The tardy recognition on the part of medical teachers of the value of electro-therapeutics, is responsible for much of the misuse which electricity has received at the hands of the charlatan. If the heir falls from his high estate, and fails to make good his birthright, there will always spring up false claimants and impostors seeking to lay hold of the neglected titles. But there are other influences at work, aside from the testimony offered in the transactions of this Association, that will naturally aid in bringing medical educators to their senses in the matter of instruction in electro-therapeutics. Agencies are now at work all over this broad land that bid fair to intensify the mortification of the so-called liberally educated physician because of his ignorance.

Schools of electricity and simple methods of instruction in its principles and phenomena are now providing information concerning it in a form so readily assimilable that the newsboy and mechanic will soon be prepared to ridicule the crude notions of the medical graduates concerning the capacities of electric energy. With the solid work done by this and kindred associations massed before it, and the light infantry methods for disseminating information to the laity on either flank, the medical college curriculum will be compelled to surrender to the demands of electro-therapeutics. Already we see symptoms of yielding all along the line. When the capitulation finally comes, there will be work enough for us to do in defining the conditions by which alone instruction in electro-therapeutics can be made of scientific value and fruitful in good results. It must be

thorough in the fundamental work of physics and physiology, and must be taught by laboratory methods. So you have each learned it by long and laborious effort. So must the student learn it, but with perfected facilities, and with the results of your experience to guide him to fuller and more comprehensive acquisitions.

And, finally, this Association has a duty to perform to the great body of medical practitioners throughout the civilized world, who look to gatherings like this for enlightenment and guidance. Here, it is presumed, that whatever electricity is capable of doing to cure disease will be made known; the best methods will be revealed; the best appliances described. With an open forum for the free expression of opinion by those who are not novices in the art, doubtful results and questionable statements should not go unchallenged. Especially should the Association exclude from publication in its Transactions any views or theories that are manifestly unsound or misleading, since by so doing it gives to them the sanction of its authority.

The reports of the scientific committees on the various forms of therapeutic appliances, appointed two years ago, and continued until now, can be made of great value to the medical profession. In the opinion of your President, these committees should be made standing committees, and it should be expected of them that each make known to us, and so to the profession at large, through its annual report, the advance and improvements that have taken place during the year in therapeutic work by means of that class of appliances under its supervision. These committees are comprehensive in the scope of work they cover, and by this plan the entire field of electro-therapeutic appliances will receive careful review and presentation at our meetings, by those well qualified for the task and who, knowing in ample time what is expected of them, will not be hurried in its execution.

If the Association thinks favorably of this proposal, I would suggest for the sake of greater efficiency that the title of the first of these committees, be changed from that of "Standard Coils" to that of "Induction Coils and Alternating Current Apparatus," since recent invention has added a class of apparatus to therapeutic facilities which has not been assigned to any one of these committees to investigate.

It would certainly appear from this brief sketch of what I conceive to be a few of the functions of this Association that it was not born without a purpose. It has, so far, given evidence that it is fully conscious of the weighty responsibilities that have devolved upon it and has laid its foundations broad and deep in its efforts to fulfill its mission and construct the edifice that will serve as a storehouse for truth in this department of science so intimately related to human welfare. Let it be our determination never to lose sight of the greatness and grandeur of the work we have so auspiciously undertaken and each year give abundant evidence of the necessity for our existence.

#### REPORTS OF COMMITTEES ON SCIENTIFIC QUESTIONS.

THE PRESIDENT—Many of us come here to learn what there is new in apparatus furnished for our work, and if we know quite early the opinions of these committees, it will materially help us in securing such additional apparatus as will give us the best aid. The object of these committees is distinctly educational. The foundation of electro-therapeutics should be broad and deep. The first foundation stone is electro-physics; the second is electro-biology, by which we mean the physiologic response of electricity in all its forms in normal tissues; and the third foundation stone is rational therapeutics. Our program is arranged as nearly as possible on this plan.

REPORT OF COMMITTEE ON STANDARD COILS  
was presented by DR. WILLIAM JAMES MORTON, of New York City.

The main functions of an induction coil are:

- (a) To cause muscular tissue to contract.
- (b) To produce a sensation of sedation. While physiologic effects produced by different coils differ, they do not differ so much but that a single secondary coil will fulfill all the requirements of a standard coil. For one and the same "long fine wire coil" will

- (a) produce vigorous muscular contractions
- (b) produce sedative effects.

Therefore, for the sake of simplicity and uniformity this member of the committee recommends,

- (a) A standard cell.
- (b) A standard primary winding of No. 22 wire of  $\frac{1}{2}$  ohm resistance.
- (c) A vibrator of a new type furnishing a given musical note.
- (d) A rheostat in the primary circuit to govern the note agreed upon.
- (e) A secondary coil of No. 32 wire, 500 meters in length.

DR. A. H. GOELET, of New York City, also a member of the committee, said that Dr. Morton was undoubtedly correct in his statement that the members of the committee could not agree. He was arguing from the standpoint of the neurologist, and what was suitable for the neurologist was not suitable for the gynecologist. A coil which would produce muscular contraction would not always produce sedation. Again, it would produce muscular contraction in some gynecologic conditions, but would not do so in others. For instance, in a sensitive pelvis or a condition resulting from inflammatory action, a fine wire current would produce painless muscular contraction and sedation, but if that same current is applied to a case of subinvolution of the uterus and vagina there would be absolutely no effect. Under such circumstances the stimulating properties of the current must be increased by increasing its volume and this can not be done with a coil of one length. At the first meeting of the Association, the speaker said he had suggested a combination of coils which he thought would answer the purpose, not only of the gynecologist and neurologist, but that of the general practitioner, and now after an experience of three years he was more than ever convinced that it would answer all these purposes. He was furthermore convinced that a one coil apparatus was suitable only for the person working in one line of work. On the external surface of the body where Dr. Morton had done most of his work, the resistances are high, and it is necessary to use a long wire coil. In gynecologic cases the resistances are very low, particularly when both poles are placed in the vagina. It was possible to produce most intense muscular contractions with a coarse and short wire in some cases, whereas with a long wire current, no effect whatever would result. The speaker said that before he had suggested this combination of coils he had worked with a battery which he brought with him from Paris. The coil he had estimated by measuring the resistance to contain about five hundred or six hundred yards of wire, yet he had found it entirely inadequate for his purpose. It was this that had led him to suggest this combination of coils. He did not mean to say that this particular faradic apparatus should be adopted, but on the other hand he thought every faradic apparatus should stand on its own merit. Hence, he agreed with the President that this committee should be a standing committee charged with the duty of testing every induction apparatus put upon the market, and of reporting on their merits or demerits at each annual meeting.

DR. MORTON said he desired to say that his distinguished fellow-member of the committee had given him a very narrow channel of work which was by no means his sphere of labor with induction apparatus. His remark had been based on an experience with all resistances, both high and low, neurologic and otherwise.

DR. GOELET said that he would like to add to what he had said that the only objection to the combination he had suggested was its expense. Therefore, he had the makers construct a battery with a coil of one size of wire (32) split up into different lengths which would answer for most ordinary

purposes and was cheaper. The cost is only one-half that of the other apparatus. It is a good cheap battery but its sphere of usefulness is limited.

#### DISCUSSION.

DR. G. BETTON MASSEY, of Philadelphia—said that his experience covered both fields of gynecology and neurology, and as a result of his experience he was inclined to indorse the views expressed by the second member of the committee. He was somewhat in doubt whether a single coil might not cover all the indications of both special and general work. There were very few such coils manufactured, and he was sure that one of five hundred yards would not be suitable. It was not only a question of the length and size of the wire, but the nearness of the core to the whole of the coil which was important. He had failed in one patient to get a high contracting power from any machine manufactured in New York, although he had searched among the instrument makers very carefully. In the one matter of current volume this high wire was lacking; one must have coarse wire in close approximation with the core in order to get a high contracting power. From such a core—one closely wound and having a moderate electro-motive force—we might get sedation also by introducing resistance into the extra current circuit, such as was obtained in the speaker's current controller. He was not sure but that low electro-motive force with slight current was capable of exhibiting all the sedation qualities of the current with high electro-motive force.

DR. R. J. NUNN, of Savannah—said he would like to ask the committee if any researches had been made as to the frequency of the interruptions, and he would also like to say that there should be some standard by which the length of the coil should be measured. The resistances in different individuals varied so greatly that while in one series of experiments a 500-yard coil might be sufficient, in another case a 1,000-yard coil might be required. He had observed this in his own experience.

MR. BROWN, of Brooklyn—said that this question of resistance had nothing whatever to do with the length of the wire or the efficiency of the coil. The whole matter depended, not upon the length of the wire but upon the number of turns. To speak of a coil as having a certain resistance and a certain length secondary coil was to give no definite idea of its value. With a given number of windings on the primary coil, and the second coil, the electro-motive force could be determined. For applications to the surface of the body high electro-motive force was wanted. This was obtained by increasing the number of turns on the secondary coil. If, on the other hand, it was desired to use a bi-polar electrode where the resistance was very low, very low electro-motive force would be required, but a very large quantity of current. By increasing the number of turns on the secondary, the electro-motive force was increased, but in the same ratio the quantity or volume was decreased. On the other hand, if short thick wire were used on the secondary coil, the resulting current would have a low electro-motive force but large quantity. A current of high electro-motive force would shoot right through the body, but one of low pressure instead of shooting through the tissues would follow the blood vessels and would have a more diffused action. It would therefore seem that the vital question was the number of turns of wire in a coil.

DR. A. LAPHORN SMITH, of Montreal—said he quite agreed with Dr. Goelet as to the necessity of having two distinct coils for the average work in gynecology. It was to this branch alone that he wished to refer at the present time. From the point of view of the gynecologist he thought two coils were required, and if he knew nothing about such a coil except what was derived from his own experience, he would

say that a short coarse wire coil produced results, as interpreted by the patient, which were very different from those obtained from the long fine wire coils. If the patient's head was covered up she could at once tell you by her sensations which form of coil was being employed; the coarse coil giving severe muscular contraction, the fine wire first a tingling sensation and then a "numb feeling" extending over a greater or less area. Some patients could even tell the operator the apparent size of this "numb" area. It would seem reasonable, therefore, to believe that two coils were necessary. There should be provided a short coarse wire coil with slow interruptions, and a long fine wire coil with very rapid interruptions. He felt that there should be some improvement in devices for regulating the speed of the interruptions. As a rule, the iron spring was too heavy for this purpose. In one instance he had substituted for it a piece of ferrotype plate and had obtained a very high musical note.

MR. CARTY, of New York City—said that he could sympathize with Dr. Morton's statement that we would not come to any agreement on induction coils for a number of years. If medical practitioners knew just what kind of current they needed they could safely leave the matter of the kind of coil to the electrician. He could say for the electrical engineers that a medical man could make no request for a current, whether to kill or to cure, that the engineer could not supply. The trouble was to get the medical practitioner to determine just what kind of a current was best suited to his purpose. The physician knew he had obtained a favorable effect with a machine of a certain manufacture and of a certain kind, but he could not accurately describe the nature of that particular current. At one of the previous meetings of the Association, some remarks had been made about recording tracings of the current. If such apparatus were perfected and put into general use he felt confident that this great difficulty of which he had spoken would soon disappear.

In answer to a question by the President as to the difficulties in introducing this graphic method more generally, Mr. Carty said there was no difficulty in the electrical engineer making such observations, but he thought it would be difficult to provide a cheap and portable apparatus which could be used satisfactorily by medical men.

DR. MORTON, in closing the discussion, said he had purposely omitted many interesting points because he felt that they should be discussed for a while longer by the members of the committee. He did not know what Mr. Brown meant by "volume." He would suppose that 500 meters of a given wire with a given primary coil and given rate of vibration would give in every instance the same graphic record. It was well known that electro-motive force was governed by the number of turns of the wire.

As to measurements, there had been some machine recently invented, particularly in Germany, for measuring the alternating and periodical current. He felt that Mr. Carty had touched the keynote of the whole future work of the committee. Monsieur D'Arsonval has attempted this, and had done some admirable work in determining the physical form of the waves of a continuous current, and of the alternating current. This observer considered the form of the current to be the best guide in determining its physiologic effect. Dr. Kellogg, of this Association, had already shown before the Association some very beautiful tracings of the currents which he had made. In defense of his own remark that he thought one secondary coil, all the other conditions being equal in each case, would answer all purposes, he would say that he recognized that a powerful muscular contraction was desirable, and also that a sedative effect was needed, a sort of static effect. In his opinion, with any ordinary sized wire and a length of upward of five hundred yards, all the

muscular contractions which any patient could stand could be obtained. He had seen the most powerful muscular contractions produced by such apparatus and under varying resistance. In addition to the muscular contractions he had also obtained a sedative effect. He thought muscular contractions and sedative effect did not need to be considered as two distinct entities; they could be obtained at one and the same time by the apparatus described. If it were desirable to obliterate the sedative effect, then he could conceive that a different coil might be needed—one that would hurt the patient—but this he did not think was what was wanted. The whole question seemed to him to be one of over-refinement in technique.

#### REPORT OF COMMITTEE ON METERS.

The requirements of a thoroughly good meter, which the committee has considered in examining the various instruments submitted to it, are practically those of last year, and in the descriptions of the various instruments which appeared in the committee's last report, these various requirements are taken up and dwelt upon individually in connection with each make of instrument.

The committee has had before it this year, meters of the following make: Weston, Kennelly, Jerome Kidder, Queen & Co.; Hirschmann (of Germany); Waite & Bartlett, McIntosh, Vetter and Flemming. The McIntosh and Kidder instruments were not among those tested last year.

The Kidder is an instrument handsomely mounted in a nickel-plated case. Its scale is clear and convenient. It is of low resistance and is made either for horizontal or vertical use. It is of a type similar to the Weston and Kennelly, and is practically unaffected by outside magnetism. As the makers say, the suspension system is very delicate and where a quick reading is desired it becomes necessary to put on a "drag" which renders the instrument practically "dead beat." In the instrument on test there were two scales, from 0 to 75 and 0 to 300; the change from one scale to the other is made by means of a plug which can be readily introduced. By putting on the "drag" the instrument can be transported without fear of injury. The makers say in a recent letter that they contemplate in the near future arranging their instruments so as to give a 250 milliampère scale as a maximum, thus giving broader lines of division.

The McIntosh instrument is one for which much is claimed by the manufacturers, the McIntosh Battery and Optical Company, of Chicago, but although the instrument is very prettily put together and makes a very nice appearance, the sample submitted to us has been found to be far from accurate. By reference to the table of tests accompanying this report, it will be noticed that through all the readings the McIntosh instrument lags behind, until the point was reached where the Weston standard read 500 milliampères, while the McIntosh showed but 250. In writing to the committee, this Company wishes it to be understood that they have never claimed their instrument was in any true sense to be considered as a standard instrument of precision, but that "gauged by correct standards it approximates very closely absolute reliability."

It was hoped that it might be possible to have a Gaiffe and a D'Arsonval instrument among the others tested, but none were available for this purpose without incurring the expense of purchasing one.

Since the last annual meeting of the Association the Galvano-Faradic Company have been working on their meter with a view to improving it, as they have appreciated from the first report of this committee that there must be room for such improvement, and as they are desirous of offering to the profession only good apparatus, have been doing their best to make their milliampère meter a success. It would seem that they have been progressing very well in this direction, but owing to a press of other work have not been able to finish up an instrument in time for the test.

The Weston instrument is in practically the same form as last year, as in the Kennelly, though the scale of the latter has been considerably improved. The strictures which were last year placed upon the Waite & Bartlett, Flemming and Vetter meters may be repeated this year, although the scale of the Vetter instrument tested is better than the one before the committee last year.

#### THE TEST.

The current for the comparative test of the meters was obtained from the street circuit of the Edison Illuminating

Company, and for convenience it was passed through a Kennelly adapted as a means of regulating the flow to the meters for the readings up to and including 200 milliampères after which a large box of variable resistance was substituted as a regulator. The fourteen meters on test were all placed in series, those having large permanent magnets being in one group and those of the galvanometer type being in another group at a considerable distance from the first. In this way the supersensitive instruments were entirely withdrawn from the baneful influences of stray magnetic lines of force from abroad. It even became necessary to take off and put away the watches of the committee, as well as any pieces of steel and iron which they might have about their persons.

As was done last year, the Weston instruments were used as a standard of comparison during the recent tests, and it would seem that this was fully justified by the absolute correspondence within perceptible limits of the readings from the different Weston instruments, as well as from the recognized position held by the Weston meter for general accuracy. But to avoid any possible doubt as to the accuracy of these standards, they were after the completion of the test, checked by Prof. F. B. Crocker, of the School of Mines, Columbia College, with a standard Thomson Centiampère Balance, the results showing very close approximations to the readings of that standard. Their use for this purpose was abundantly justified.

The following table shows the readings of the instruments with certain corrections made necessary by the fact that in the case of the Kennelly, the Kidder and Queen instruments, the needles were slightly off zero to begin with, due possibly to jars received in transportation.

Make of Instrument.	MILLIAMPERES READ IN TEST.

NOTE.—The scales of each make of meter marked with a star (\*) are on the same instrument; it is thus shown that there were two Westons and one Kennelly instrument in the test, etc.  
 † This Kennelly meter has been in constant use a year without re-standardizing.

We consider that in all these cases there was no inaccuracy indicated by the erroneous starting point beyond acci-

dental bending of the needles, and that for these reasons they were entitled to these corrections. In this table, the Weston scales which were used as standards during the various portions of the test are indicated by heavy type. It might also be said that the Kennelly meter, marked with a dagger, is one which has been in use without re-calibration for over a year. In this connection it might be stated as the opinion of the committee that it would be advisable for any one using milliamperè meters, of whatever make to have them re-calibrated at least once a year.

As the meters were of different maximum capacities it became necessary to drop some of them out as the readings progressed into the higher ranges, and when maximum reading of any instrument was reached the comparative temperature of that instrument was observed. There was no apparent over-heating observed in any of those on test, and this is noteworthy because most of the meters were subjected to a gradually increasing current for about three hours.

The matter of the graduation of the scale was very carefully considered by your committee and they are disposed to believe that it would be better to have a double scale in the more expensive instruments. There is no doubt that it would be best for oculists and aurists who use small current strength, say from a fraction of a milliamperè to three, four, ten or twenty-five, to have a separate meter with a proper special scale, while a meter constructed so as to read from 1 to 25 and then in five milliamperès up to the highest number on the scale would be more desirable for general use. Among the Weston milliamperè meters is one which combines a fine scale from 0 to 10 graduated in tenths of a milliamperè, and a second scale from 0 to 500. This is applicable to the needs of all practitioners.

Your committee has also considered the question of the advisability of a meter reading as high as 500, and are of the opinion that it is not of general use and the cases are exceptional where higher reading than 100 is required. In hydro-electric methods and in the Inglis Parsons treatment of cancer, a scale reading as high as 500 is desirable, but in average medical work there is no need of a higher reading than 250, while even that is of doubtful necessity. It is not necessary, in order to determine whether the current is flowing in the right direction through a meter, that the meter should be so arranged as to read from a scale on both sides of the zero mark. In fact, a meter whose zero is in the center of the scale sacrifices clearness and range for an imaginary convenience, provided that an opportunity is given for the needle to move backward to a certain extent with a wrong direction of current flow. This opportunity almost invariably exists.

#### POSITION OF METER.

A meter should be so placed in an office as to avoid the influence of any magnetic field caused by masses of metal or circuits carrying light or power currents. Such field may sometimes have its center outside the apartment in which the instrument is located. When placed upon a table, cabinet or horizontal switchboard, a meter is liable to be affected by vibrations, particularly accidental jars to the entire board. The horizontal position is always the best, because a meter so placed is not affected by gravity, while in the use of a vertical meter, unless perfectly counterbalanced, gravity will sometimes retard their operations and sometimes assist them. The easel position of the Queen meter is a very convenient one to the operator for reading. Your committee would recommend, however, that meters should be suspended from the wall by elastic cushions or bearings, and where such suspension makes the act of reading inconvenient, it may sometimes be assisted by placing a mirror on the wall behind the instrument.

#### MAGNETIC SHIELD.

The matter of a magnetic shield or encasement to prevent the effects of an exterior magnetic field such as results, for example, from an operating motor near at hand, has been considered by your committee. It is not deemed necessary either in the Weston or Kennelly meters. It is not advisable to use these meters close to a strong magnet, not only on account of stray magnetic leakage influence, but because it is possible (though difficult) to alter the results secured by their permanent magnets, by an accidental powerful field in their vicinity. Ordinary care, however, is all that is necessary with instruments thus constructed. Other instruments such as the Waite & Bartlett, McIntosh, Flemming, Vetter, etc., would be strongly affected by a similar disturbing influence of less power, and can not be expected to be controlled by ordinary care for, as has been indicated here-

tofore in this report, it was necessary to lay aside watches, keys, pocket-knives, etc., before coming near any of these instruments.

#### VOLT METERS.

While there was no actual test made of volt meters, yet your committee would report in favor of the Weston volt meter or the one manufactured by Queen. The Weston volt meter used in certain experiments, which will be detailed, is generally recognized by electrical engineers as being an excellent instrument.

#### WATT METERS.

Your committee have considered the advisability of securing a watt meter which will directly indicate the amount of energy expended in a given treatment. The matter was looked into with considerable care and it was decided that to get a watt meter of sufficient delicacy, considerable time and expense would be required. Owing to the fact that the amount of energy used by physicians in their applications is so very small, such an instrument would necessarily be extremely delicate and therefore expensive. All the requirements can for the present be met by the combined use of an am-meter and a volt meter, which instruments possess independent and separate usefulness, whereas a watt meter as ordinarily constructed could only be of special value for its own indications. It was, therefore, decided to consider the use of a volt meter and am-meter together, the connections being made in such a manner as to place the volt meter in shunt with the patient, plus the am-meter of negligible resistance and thus measure the fall of potential between the electrodes. By multiplying the amperage and the volts, the number of watts of power expended in a circuit between the volt meter terminals will be obtained. Given the number of watts, the energy in electrical horse-power may be readily obtained by dividing by 746.

It is desirable that there should be the best electrical contact at all binding posts and shunt switches, especially where, in a test for watts, the volt meter spans the am-meter as well as the subject operated upon, otherwise the amount of power being expended upon the individual will not be correctly indicated. Where a meter is permanently mounted upon a cabinet or switch-board, the binding posts should be provided with lock-nuts or equivalent devices to prevent impairment of contact.

In this connection the following observations may prove of interest. The volt meter used in all these experiments was the Weston.

The above diagram represents a volt meter in the circuit so as to get a reading both of volts and amperes or fraction thereof. By multiplying volts by amperes the number of watts is obtained, while dividing this product by 746, the number of watts to an E. H. P., the E. H. P. used is determined.

H. E. C. Fibroid tumor with exudates on right side. A hydro-electric application given with the vaginal douche electrode, two and one-half quarts saline solution, an Apostoli pad over the abdomen, forty-two square inches in area. Pressure 53 volts, c. s. .060 of an ampère. The voltage multiplied by the ampère gave 3.1 watts. This divided by the number of watts in E. H. P., namely 746, gave .004 of an E. H. P., the power or the rate of energy. The resistance was 8,830 ohms.

M. E. S. Goitre. Indifferent electrode, hands in gallon jar of salt water, active, negative, eighteen square inches in area over growth. Pressure, 56.75 volts, c. s. .020 of an ampère, giving the power or the rate of expanding energy at 1.1 + watts or .001 + E. H. P. The resistance in this instance was 2,837.5 ohms.

M. A. Facial Acne. Electric douche to face, pressure 57

volts, hands in saline solution, c. s. .010 of an ampère, the rate of expanding energy .5 watts or .0007 of an E. H. P., resistance 5,700 ohms.

M. A. Vaginal electric douche, saline, negative, indifferent electrode, abdominal pad forty-two square inches, pressure 52 volts, c. s. .050 of an ampère, watts 2.6 or .003 E. H. P., resistance 1,040 ohms.

M. E. S. Hemorrhoids. Treatment, cupric electrolysis, indifferent electrode abdominal pad thirty-six square inches, pressure 56 volts, c. s. .018 of an ampère, watts 1.4 or .001 E. H. P. Resistance 3,111 ohms.

M. E. S. Vaginal electric douche, negative, pressure 55 volts, c. s. .040 ampère, 2.2 watts or .003 E. H. P. Resistance 1,375 ohms.

H. E. N. Vaginal electric douche negative, pressure 55 volts, c. s. .050 of an ampère, 2.7 + watts, or .003 + E. H. P. Resistance 1,100 ohms. Condition, chronic vaginitis, with eczema of the vulva.

E. C. M. Chronic peritonitis, sacro-abdominal (per cutaneous) application, electrode thirty-six, and forty-two square inches in area, pressure 90 volts, c. s. .025 of an ampère, 2.25 watts or .003 E. H. P., R. 3600 ohms.

P. H. Gonorrheal vaginitis, vaginal electric douche cataphoric  $\text{Ca}_2 \text{SO}_4$ , 6 grs. to qt., 3 qts., indifferent electrode, abdominal pad 42 square inches, negative, pressure 110 volts, c. s. .008, ampère .880 watts, R. 13,750 ohms.

These experiments give in recognized units of measurement the rate of expanding energy in given treatments. They do not cover a very wide range of applications, owing to the fact that in very busy office life one has not always the time to take the measurements and make mathematical calculations. However, these observations are going on from time to time, and are intended in time to cover as wide a range of applications as can be made in the treatment of disease by the constant current.

NOTE.—The following is the result of the examination of the two Weston instruments, used as standards, by Prof. F. B. Crocker, of the School of Mines, Columbia College, with a standard Thomson Centiampère Balance:

No. 204 Thomson Balance.	No. 2272 Milliampère meter.	No. 2131 Milliampère meter.
25.45 milliampères.	25.	25.
50.	50.	52.
75.15 "	75.	76.5
100.25 "	100.	100.5
151.	150.	151.
204.2 "	.....	200.
249.8 "	.....	250.
298.6 "	.....	300.
99.6 "	.....	500.

NOTE No. 2.—Before submitting this report, it is with pleasure we note that the McIntosh Manufacturing Company have about ready for the market a new and improved milliampère meter which promises to be an exceedingly valuable instrument. It was not completed in time for the test this year, but we trust that it will be placed in the hands of the committee during the year.

#### RECAPITULATION OF SUGGESTIONS.

Meters should:

1. Be re-calibrated once a year.
2. Be constructed to indicate fractions of milliampères on one scale to a predetermined point, and higher currents on a second.
3. Be (ordinarily) required to indicate only up to 100 milliampères.
4. Be placed in a horizontal position.
5. Be flexibly suspended from solid support.
6. Be re-inforced by a mirror to assist in reading the scale.
7. Be provided with magnetic shields when not made with strong permanent magnets.
8. Be capable of indicating either direction of the current, but measuring it in only one direction.
9. Be furnished with reliable binding posts and shunt switches.

Signed, MARGARET A. CLEAVES, M.D.,  
Chairman.

W. J. JENKS, E.E.  
ENIL HEUEL, M.D.

#### DISCUSSION.

DR. MORTON said that as there was frequent occasion to reverse the current he could not understand what was meant by recommending meters which would register in only one direction.

THE PRESIDENT said he considered this kind of work an extremely important part of the labors of the Association.

Within the last three years he had found considerable benefit from using extremely small continuous currents—those registering one-tenth of a milliampère or less. From this it would seem that the scale should be even more finely divided than that recommended by the committee. He was satisfied that there was important use for constant currents, if not for other currents, of very low ampère continued for a long time.

DR. MORTON said that he thought it would be desirable in the future to report upon what provision could be made for measuring the current more minutely.

DR. DICKSON said that last year he had spoken about the beneficial effects he had observed from currents of one-tenth to one-fifth of a milliampère. In his work at the Toronto General Hospital he met many specialists and he found that the oculists were especially interested in electro-therapeutic work. In some of the ophthalmologic cases one-half a milliampère would not be tolerated, hence the importance of improving the scale in the direction just suggested. The report of the committee was a most excellent one.

DR. MASSEY said he wished to take exception to the slighting remarks made as to the possible value of very heavy currents, although he appreciated the value and importance of the work of the committee. He thought we occasionally needed meters which would register 500 milliampères or more, particularly in cases of cancer or of highly vascular tumors in cavities contiguous to the surface of the body. Under anesthesia, one might easily use from five hundred to one thousand milliampères of current in that way, and so increase the surgical possibilities in this direction.

DR. CLEAVES, in closing the discussion, said that the objection to meters registering both ways was that it interfered with the clearness of the scale. Some of those who had spoken, seemed to have lost sight of the fact that the committee had recommended that the meters should read as minutely as one-tenth of a milliampère. The remarks made by Dr. Dickson on this subject at the last annual meeting did not refer to the use of such a current, but to whether the instrument could be depended upon for such minute measurements. The value of heavy currents was not lost sight of and readings of 500 advised for special work.

The Association then adjourned at 12:30 A.M.

(To be continued.)

**Ligature of the External Iliac Artery.**—At the *Société de Chirurgie* of Paris, held in December, 1894, M. Chauvel, reported the case of an Arab child who had been wounded in the thigh by a pocket knife. It immediately resulted in a spurting hemorrhage, which spontaneously ceased, but recommenced after six hours. On admission to the hospital a compress bandage was applied and left in place for eight hours. When it was removed the clot was thrown out and the hemorrhage was again active. M. Nicot decided to ligate the external iliac, which was done without chloroform, by cocaineization. Cure by second intention resulted. On the thirteenth day there was secondary hemorrhage which was arrested by direct compression. Some days afterward there was gangrene of the foot which was self limited and the child recovered. The reporter was of opinion that it would have been preferable to seek for the divided ends of the vessel and tie them in the original wound.—*Revue de Chirurgie*, Jan. 10, 1895.

**Adulterating Olive Oil with Castor Oil.**—Olive oil is found to be frequently adulterated with castor oil. It is even claimed that the olive, especially if it has become strong smelling or rancid, is improved by the addition. As much as 20 per cent. of the adulterant may be added without detection. "An Italian expert," says *Food and Sanitation*, "claims its presence may be discovered by taking 10 cc. of the suspected oil, mixing it with half its volume of hydrochloric acid, and then shaking them together in a test glass graduated to 0.1 cc. If any castor oil is present the liquid will separate, on standing, into three well-defined layers, the lowest of which will be the hydrochloric acid, the top the olive, and the middle the castor oil. This test may also be used with sesame, cotton seed, colza, earthenut and linseed oils."—*Pharmaceutical Era*.

PUBLISHED WEEKLY.

## SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE . . . . . \$5.00  
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.  
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

## MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, FEBRUARY 23, 1895.

## THE PREVENTION OF BLINDNESS.

The census of 1880 as compared with the census of 1870 showed an apparent increase in the number of blind, very much greater than the increase in population. Attention was called to this by a paper read before the American Ophthalmological Society and a committee was appointed to examine into the cause of blindness in the United States. In the report of this committee it appears that in this country, as in Europe, at least 15 if not 20 per cent. of all the children in blind asylums are there because of purulent conjunctivitis of childhood, and stress was also laid upon the fact already well known that when these cases receive proper attention in the very early stages of the disease the number of unfortunate cases is reduced to a mere fraction of 1 per cent. Evidently, then, it is simply a question as to how these children can be brought promptly to the attention of some one who is supposed to be qualified to treat them, or if he fails to do so can be made responsible to the parents. In other words, the natural inference was the advisability of legislation which should require nurses and midwives to report these cases at as early a stage as possible to some legally qualified practitioner. There were, naturally, many other causes of blindness referred to by that committee, and various suggestions made in regard to those forms, but we wish to invite attention at present to the blindness caused by ophthalmia neonatorum. When these and similar facts were formally presented to the Legislature of the State of New York by another committee of medical men, a bill was unanimously passed known as chapter 41 of the law of 1890 and read as follows:

## AN ACT FOR THE PREVENTION OF BLINDNESS.

SECTION 1.—Should any midwife or nurse having charge of an infant in this State, notice that one or both eyes of such infant are inflamed or reddened at any time within two weeks after its birth, it shall be the duty of such midwife or nurse so having charge of such infant, to report the fact in writing, within six hours, to the health officer or some legally qualified practitioner of medicine, of the city, town or district, in which the parents of the infant reside.

SEC. 2.—Any failure to comply with the provision of this Act shall be punishable by a fine not to exceed one hundred dollars, or imprisonment not to exceed six months, or both.

SEC. 3.—This Act shall take effect on the first of September, eighteen hundred and ninety.

Slight changes were made in this law subsequently, the wording being retained practically the same, but for the sake of convenience and for greater efficiency it was incorporated into the penal code. Following the example of New York, almost exactly the same law was passed by Maine in 1891 and by Rhode Island and Minnesota in 1892.

Meanwhile, at the Milwaukee meeting of the AMERICAN MEDICAL ASSOCIATION a paper was read by one of the members of the Ophthalmological Section calling attention to the reasons for such legislation and showing what had been accomplished in that direction. The discussion which followed the paper resulted in the unanimous indorsement of the advantages of such legislation and the Section reported a resolution appointing a committee of five whose duty it should be "to urge in all parts of the country, by personal application, by circulars to physicians and legislators, and by blank forms of a desirable law, such legislation as will tend to lessen the blindness caused by this disease." The committee consisted of DR. LUCIEN HOWE, DR. HENRY GRADLE, DR. GEORGE M. GOULD, DR. JAMES L. THOMPSON, and DR. G. C. SAVAGE. Last year a similar law was passed in Maryland and Ohio, and this year bills have been either presented or soon will be presented in the Legislatures of several other States.

The general plan in each of the States has been about the same. At the suggestion of this central committee, appointed by the AMERICAN MEDICAL ASSOCIATION, one or two leading ophthalmologists in the different States have been asked to read papers at the meeting of their State medical societies, calling attention to the dangers of ophthalmia neonatorum when the cases are neglected, and the excellent results obtained when these cases are seen in the early stages, and citing the increased cost to the State for indigent blind who are in that pitiable condition, usually in consequence of the negligence of midwives and nurses. Following these papers, resolutions have been adopted by the State medical societies, strongly indorsing some form of legislation to abate this evil and appointing a committee to take charge of the matter. This committee has then gone before the Committee on Public Health in the two branches

of the Legislature and presented the reasons for the existence of such a law.

In Pennsylvania an excellent paper was read by DR. GEORGE M. GOULD at the last meeting of the State medical society. A series of strong resolutions were adopted by the society indorsing this law. A committee now has the subject in charge and will have it presented at an early date. In Vermont such an act has been read twice and referred to the joint Special Committee on Public Health. In Michigan and Illinois, bills have been introduced in the Legislature at the instance of the State medical societies, and in the latter State the interest of the governor has been enlisted in securing its passage. In California, the bill goes before the Legislature with the unanimous indorsement of the leading medical societies of the State. In New Jersey a bill has been drawn up and will be presented to the Legislature at this session. In New Hampshire it is before the Legislature. In Indiana and Connecticut it is before the Committee on Public Health.

There are other States in which the question of such legislation is being agitated or advised, and it is earnestly hoped that before many years such a law will exist in every State of our glorious Union.

#### THE CARE OF THE INEBRIATE.

This question comes more and more frequently to every general practitioner in the country. Within a comparatively recent period it has become a well recognized fact that the inebriate is diseased and curable by medical means and measures. The class of cases curable and the exact remedies and appliances for this purpose are not so well defined, and like all other new questions is open to some differences of opinion.

The appeals of friends and relatives of patients, and even of patients themselves, to the physician for help are touching and very urgent. In some vague, half-defined way the average medical man may recognize the possibility of help from drugs, but the uncertainties of medicines and his doubtful knowledge turn him to ethical and moral lines of treatment. He gives placebos and severe lectures to the patient, threats, warnings, appeals, and accepts pledges and promises. He may go beyond this and administer secretly, medicines to produce nausea, or narcotics to check the morbid impulses. In one case a disgust for spirits is expected to give power to abstain in the future; in the other, checking the drink craze, is supposed to destroy it. The latter is always disastrous in turning the drink craze into other and even more incurable channels. Many good physicians, in despair of other remedies, have turned to morphin by the needle, and secured temporary relief, only to find that, later, morphinism was developed. Chloral, cocain, and many other drug

habits have begun in this way. The not infrequent failure of the family physician to successfully treat these cases, has opened wide the door for quacks and quack remedies.

The wild wave of gold cure specifics was only possible through the failure of physicians to recognize the physical nature of inebriety, and failure to give these cases the care and attention they deserve. Some few physicians seemed infected with the charlatanism of the secret gold cure remedies, and believed the loud boasts of supposed cured victims was sound evidence of success. Such persons ignore all facts of the physiologic action of certain drugs, and psychologic laws and forces, and manifest credulity that reflects sadly on their scientific training. While the injuries and diseases from the use of spirits and drugs require a considerable part of the physician's time and work, he has most unfortunately not studied the physical side of inebriety, but been content with the half moral and half physical theories of reformers and non-experts. As a result he is unable largely to do anything or even to advise soundly as a scientific man. Theories of inebriety and alcohol popularly held to be true, do not bear the tests of accurate inquiry, and opinions that are without any bases of facts are repeated from side to side as if beyond question, when in reality they are simply delusions. The few men who have made a study of this problem in many circles are still called cranks and extremists, while the positive dogmatist, who claims full and explicit knowledge on all phases of this subject is the medical hero of the hour. An ever increasing number of thoughtful men in the profession begin to realize that this drink problem has a very important medical side which when carefully studied, will enable the physician to answer the despairing cry: "What can we do with the inebriate?"

The physical study of the inebriate (whose drink craze is a symptom), of distinct conditions and causes that can be known and prevented, is the only true road to successful treatment. The physician must realize that appeals to him for help, come from organic suffering, the same as in other diseases. It is not damaged morals and ethics of conduct; it is a cry for relief from a morbid impulse to suicide, and to escape the injury from alcoholic poisoning. If each case is studied as one of disease, the remedies and means of relief will be apparent. Medical colleges should take up this subject and give its advanced students some instruction along this line, for inebriates are often among the first persons they will be called to treat.

Physicians who have studied the inebriate along lines of exact science, are agreed in asserting that the successful treatment of the inebriate should be begun by the family physician at home. That the physician should be able to prevent and cure the

inebriate in the early stages; and in the near future this will be done with as much certainty as other diseases are now treated. This is confirmed by the experience of practical men in individual cases everywhere. It seems a reflection on medical skill that these armies of inebriates should grow up and go down to destruction in every town and city of the country, with no help from medical art. The few small asylums where these cases are treated, are practically lost and insignificant in the scope and limits of their work.

The boasting charlatan occupies the field with his specifics, and the wilder dogmatists and reformers, are struggling to reach this disease by the pledge, the prayer, and the promise. Evidently the answer to the appeal for help, addressed to physicians everywhere must come from a great revolution of public sentiment in regard to the inebriate and his malady. In the meantime, physicians should study these cases more earnestly, and seek to know the causes and means for relief that are only possible by accurate study. Then this question can be answered, and a new field of cure and prevention will be opened.

#### THE INSPECTOR-GENERAL OF THE ARMY ON HOSPITAL CORPS DRILL.

The report of the Inspector-General of the Army has the following with regard to the Hospital Corps:

"The instruction given in the Hospital Corps has continued throughout the year and in some instances with results approaching perfection. The company of the Hospital Corps at Fort Riley has had under instruction 100 men, 53 of whom have been transferred for duty to other stations. At date of inspection the company was partially armed with carbines, revolvers and knives, and, as reported, was devoting three-quarters of an hour daily to carbine drill.

Admitting without question the very great necessity to an army of a Hospital Corps, it is not easy to understand why its members should be instructed in the military use of any such weapon or in what way such instruction prepares a recruit for the duties of dressing injuries or nursing the sick. On the other hand, there is a manifest impropriety in giving arms of any description to a soldier of the Red Cross, whose duties do not demand it and whose neutrality in time of war renders it wholly unnecessary.

Another view of this subject is presented by the facts: If it be found necessary to the proficiency of the Medical Department that its members be trained as combatants, then a return to the old system under which those who now compose the Hospital Corps were recruited would probably subserve the best interests of that department. Only soldiers who have proved their aptitude and efficiency for the duties were transferred as a rule, and having already been instructed in the use of arms, there was no encroachment on their time or that of medical officers for that purpose, and no temptation to turn from the legitimate duties of the Medical Department to those which are wisely intrusted to other hands."

It may be added that the "Drill Regulations of the Hospital Corps" provides for no rifle or carbine drill.

Rifles are mentioned only in connection with the extemporization of litters; and each detachment of the Hospital Corps is furnished with a few rifles for use in practicing such extemporizations. The criticisms of the Inspector-General would be relevant only if these drills were general or called for by War Department orders. Local commanders are not prohibited from putting carbines into the hands of raw men for purposes of drill. No doubt they may, if they please, make use of this arm just as they may make use of any article of the outfit of the gymnasium.

#### CLEVER MALINGERING.

The Chicago daily papers have recently contained an account of the operations of a family of sharpers who have victimized railroad corporations. Their plan of operations consisted in having a member of the family feign paralysis, which it was asserted had been brought about by a fall while on a railroad train or street car. In almost all of these cases a convenient banana peel was the predisposing cause while a jolt or sudden start of the conveyance furnished the exciting factor. An investigation of an attempt to obtain money from the Chicago, Rock Island & Pacific Railroad led to an exposure of their numerous efforts in Chicago and Boston to extort money from railroad and street car companies.

It seems that one member of the family had succeeded in so far overcoming natural sensibility that she would allow pins to be thrust into her skin without flinching. The usual claim was a complete motor and sensory paralysis of the lower extremities.

The following is a copy of one report made by a physician of Boston:

"FANNIE FREEMAN has double vision. One object appears as two at times, and her vision is blurred. She has photobia or dread of light; is unable to move her limbs in bed. Examination shows scrapes along the spine. Tenderness to pressure and percussion over the lumbar and dorsal vertebræ. Can't stand, walk, or sit unless completely supported, and then can only be held in the half sitting and half reclining position, all the time evidencing great agony. Reaction of pupils normal. Tongue clean, pulse 90 at the beginning of examination and 80 at the end. Apparent anesthesia of the lower limbs. When I stuck pins into her legs and feet and touched them with my hands she declared she could not feel any sensation, and I couldn't surprise her into painful expression. Her feet felt cold to me; knee-jerk normal. It was evidently painful for her to be moved, either to be got up or to be turned from her back to her side in bed. She sees no gain or improvement in her condition, and thinks at times she is going to die."

We are at a loss to understand how so transparent a fraud could have so long escaped detection. Had she chosen to confine her operations to "traumatic neurosis" or "spinal concussion," one could readily understand how deception could have succeeded. A

total paralysis, sensory and motor, of both lower extremities could mean only a lesion of the cord and this would soon have been followed by atrophy and changes in the electrical reactions. A complete motor paralysis of both lower extremities without palpable atrophy, associated with a normal knee jerk, is certainly so rare that it ought at once to excite remark.

#### REDUCED FEES AND INCREASED RISKS.

A prominent life insurance company has notified its medical examiners that their fees will be reduced from five dollars to three dollars for examinations. The following, quoted from a circular letter, is the argument advanced—presumably in all seriousness—for the reduction: “The considerations which have led up to this conclusion are that the company has in the past placed in your hands a considerable amount of business, and, should you accept the proposed terms, it is its intention to continue to give you as much business, if not more, than heretofore. The company feels that it stands in the same relation toward you that a patient stands in toward his attending physician. A physician charges five dollars a visit for occasional visits where he would hardly feel warranted in charging so large a fee for regular medical service extending over a considerable length of time. In the latter case it certainly is the uniform custom among physicians in making out their bills to make considerable reductions from the fee for a single visit on account of the number of those visits.”

The letter then goes on to say: “Of course we do not know whether you will feel warranted in accepting this reduced fee and in continuing to serve us as our examiner.” It occurs to the JOURNAL that the doubt which should exercise the company’s mind is whether its policy holders—who are, in effect, its stockholders—“will feel warranted in accepting” the kind of risks which the three dollar fee will be apt to pass. The examination of the present policy holders involves the exercise of professional skill and ability, not too highly paid for even by a five dollar fee. How will they relish seeing the value of their policies and their prospective profits impaired by the accession of lives admitted on a scrutiny 40 per cent. less thorough—measured by the fee—than that to which they were subjected?

It is highly probable that, as our cotemporary, the *American Practitioner and News*, pithily puts it: “The public will look askance at any one of the would-be leading companies that will in any way cheapen or weaken its most vital safeguard.”

#### THE DEPARTMENT OF PUBLIC HEALTH.

Senate bill No. 1840, introduced by SENATOR GRAY, of Delaware, is the bill recommended by the Committee of the AMERICAN MEDICAL ASSOCIATION. It

antagonizes none of the Public Services and there is no reason why there should be any opposition to the bill. The Marine-Hospital Service will ultimately be greatly strengthened by this bill, and the other medical branches of the Government, under the terms of the proposed Act will have frequent opportunity for consultation and appropriate work. A supplemental bill recasting the relations of the Marine-Hospital Service, the only Public Health Service now in existence, will undoubtedly be required, for with the creation of the new Public Health Department, there will be every reason why that excellent Service should become its executive arm. There no longer exists any reason why the financial department of the Government should assume direction of a Service that has worked out the problems of national quarantine, sanitary inspection of vessels, and is now operating its great laboratory in the direct interest of the public health.

The lateness of the session may possibly prevent action this year, but without doubt the AMERICAN MEDICAL ASSOCIATION will finally succeed in passing this great public measure.

#### THE STREETS OF NEW YORK CITY.

The experience of New York City in the matter of street cleaning has well demonstrated the great advantage to the public, of securing competent and thoroughly qualified men for the conduct of technical departments of municipal governments.

The reform Mayor of New York, MR. STRONG, could have selected no one better qualified for the street cleaning department, than that well-known sanitary engineer, GEO. E. WARING, Jr., formerly of Newport, Rhode Island, and now of New York City, an active member of the American Public Health Association.

Already in the business portions of the down town district, the paving stones have reappeared, the gutters have been cleared, and Broadway presents a clean and tidy appearance quite to Bowling Green.

We are assured that the adjacent districts will soon feel the refreshing effects of the Colonel’s scrubbers as soon as possible. In the meantime those of us who have occasion to watch the vagaries of our unfortunate municipalities will rejoice that our leading city, has had the good sense to place a man at the head of one of its most important sanitary bureaus, who is not only a “scholar in politics,” as the current phrase goes, but is at the same time a competent sanitary engineer.

#### CORRESPONDENCE.

##### Leprosy and its Diagnosis.

PHILADELPHIA, Feb. 9, 1895.

To the Editor:—As one who for many years has studied leprosy, and who, moreover, has had opportunity of observing many cases in this and in other countries, I write this

note with the view of calling forth additional information upon the "Report of two Cases of Leprosy in native-born Citizens of Ohio," by Dr. J. G. McDougal, of New Lexington, Ohio, in this JOURNAL, Feb. 2, 1895. The history and symptoms are in several ways remarkable, so much so that one familiar with leprosy might be inclined to question the correctness of the diagnosis without further facts and proofs being given. It is not the intention of the writer to criticize the report at present. It may, however, be stated that it is very unusual for leprosy to develop at the age of "fifteen months." It would, moreover, seem probable that the affection of the "nose and upper lip" from which the father at one time suffered was not lepra, but may have been syphilis. There seems to have been not even a suspicion that the father had at any time symptoms resembling those of lepra; nor that these children ever came in contact with a known leper.
